FRUIT.—137 bunches of Grapes were staged, many of them being of a high order of merit, but the awards in several of the classes were made in the most indiscriminate manner possible, except in cases where size of bunch, form, and finish went together. Red-berried Hamburgs, Madresfield Court, Lady Downe's, Alnwick Seedling, and Mrs. Pince, and green-berried Duke of Buccleuch, Golden Champion and Foster's Seedling had no weight whatever with the Judges in question (we are going by their awards) so long as the bunches were larger. Neither had symmetry of outline anything to do with a show bunch of Grapes unless it had size also to commend it to their notice. Such was the standard of excellence set up by the gentlemen who made the awards on this occasion. The most palpable errors of judgment were manifest in the collection of six varieties, the three-bunch Black Hamburg class, and the second prize stand in the any other black variety class, as well as the stands in the collection of six bunches, distinct, to which first prize was awarded, most decidedly should not, in the opinion of competent judges present at the Show, have been placed in the prize list at all. Having made the above remarks, which the necessity of the case and the interest of the Society, exhibitors, and Grape culture in the district call for, we will proceed with a summary of the awards as they were made.

For a selection of six bunches of Grapes distinct—First, Mr. W. C. Rafarel, showing Madresfield Court, Duchess of Buccleuch, Alnwick Seedling, Duke of Buccleuch, Lady Downe's, and Golden Champion. Second, Mr. H. W. Ward, with Gros Maroc, Madresfield Court, Foster's Seedling, Muscat of Alexandria, Black Prince, and Alnwick Seedling. Extra, Mr. James, gardener to Sir John Walrond. Six collections were staged. Four good collections of ten kinds of fruit were staged in competition for the silver cup presented by Messrs. R. T. Veitch & Son, the well-known nurserymen of Exeter. First, Mr. H. W. Ward, Longford Castle, Salisbury, showing three bunches each of Muscat of Alexandria and Alnwick Seedling Grapes, Providence Pine Apple, Captain Lark's Melon, Pine Apple Nectarine, Dr. Hogg Peach, Moor Park Apricot, Old Orleans Plums, Morello Cherries, and Brunswick Figs, which was the weakest dish in the collection. Mr. D. C. Powell, gardener to the Earl of Devon, Powderham Castle, was a very good second, showing good Grapes, Pine Apple, &c. Mr. Bull, gardener to General Buller, also showed well in this class.

There were nine lots of Black Hamburg Grapes staged, the first prize being awarded to Mr. G. P. Benmore for three immense bunches, consisting of medium-sized red berries. Second, Mr. James, with medium-sized compact, well-finished bunches. Several other good lots were staged in this class. For three bunches of Muscats there were four entries—first, Mr. J. H. Stevens, gardener to C. D. Cave, Esq., for three grand bunches. Second, Mr. J. Barnes, gardener to P. C. Daniels, Esq.; the same exhibitor being again easily first with well-proportioned and superbly finished bunches of Alnwick Seedling in the class for any other black variety than Hamburg, the second being awarded to three rather loose bunches of the same excellent Grape, the berries being somewhat green about the foot-stalks, in preference to three large well-formed and well-coloured bunches of Madresfield Court belonging to some local grower. There were seven exhibits of any other white than Muscat of Alexandria shown. First, Mr. H. W. Ward with Buckland Sweetwater, the three weighing over 12 lbs. Second, Mr. J. Barnes with three loose bunches, but having large well-coloured berries.

Mr. Bull had the best Pine Apple, and Mr. Ward the second best. Mr.

James had the best of Peaches, showing even well-coloured fruit of Princess of Wales; second Mr. Mairs, gardener to Sir John Shelley, with Crawford's Early. Ten dishes were shown, and for nine Nectarines there were a like number of entries, the first prize going to Mr. W. Seward, gardener to Sir H. Davie, for a nice dish of the Pine Apple; second Mr. J. Drew. For one green or white-fleshed Melon, first Mr. W. Seward; second Mrs. Hart. Ditto scarlet, first Mr. Mairs; second Mr. Geeson, gardener to Lord Haldon, Haldon House, Exeter, with R. ad's Scarlet. For nine Apricots, Mr. Mairs was first, Mr. Powell being second. There were thirteen dishes of excellent fruit shown in this class. There was only one dish of Figs—excellent fruits of Castle Kennedy—staged, and for which Mr. Geeson deservedly secured first prize. Mr. Geeson was also first for nine Pears, showing good fruits of Beurré Giffard, and out of nine lots of dessert Apples, Mr. Mairs was first with a good even fruit of Red Joaneting. Second Mrs. Ensor. Mr. Underdown, gardener to Sir John Kennaway, Bart., had the best dish of kitchen Apples, and Mr. Powell the second best. The last named exhibitor had the best dish of yellow or green Plums, showing good fruits of Coe's Golden Drop. Second Mr. Seward. And for a like number of red or purple fruit, Mr. Lang, gardener to Lord Poltimore, was first with good Kirke's. Mr. Powell had the best dish of Morello Cherries, and Mr. Mairs the second best.

VEGETABLES.—These, as regards the collections and single dishes, were shown well in quantity rather than in quality, and without any attempt at dishing up, one collection covering as much space as a like number of dishes of specified quantities in two collections as staged in London would cover. For collection of twelve kinds, first Mr. Sparks, second Mr. Leach. Mr. Ward had the best dish of twelve Tomatoes, showing Stamfordian, and Mr. W. Rowland the second best. We may be excused for suggesting that at future exhibitions of this really good south of England Show the address as well as the names of gardeners and their employers be given on the individual exhibition cards.

Not for competition plants, &c., Messrs. Locombe, Pince & Co., and Messrs. R. Veitch & Son, both of Exeter, showed a grand lot of plants, consisting of choice stove and greenhouse, fine-foliage, and flowering plants. Messrs. Veitch's plants of single and double-flowering Begonias being remarkably good, the flowers large, well-formed, and the colours well defined. This firm's Pelargoniums were also very good. Messrs. Curtis, Sanford & Co. also contributed some good stands of Roses of Merveille de Lyon, Marechal Neil, and other varieties.

GRAPE-GROWING AT BATH.

I AM happy to be able to somewhat alleviate the fears of "J. S. W." that the extension system of Vine-growing is in danger at my hands. So far from that being the case I have as yet seen nothing to induce me to alter the views expressed in the sentences he quotes from my book. I will endeavour to explain what may appear an inconsistency.

"W. I." remarks, "The position chosen is on a rather sharp declivity with a south-west aspect, a great amount of excavation being necessary before the vinery could be built." Thus one side of the house faces the south-west, and stands well out of the ground, and this is planted entirely with Muscats. The north-east side, in addition to its less favourable aspect, is also below the ground level, and although everything is done that can be done for it I never expect the Vines to flourish there as they will on the more favourable side, and probably they will only remain there temporarily till those on the south-west side grow quite across.

In addition to the disadvantages mentioned all the young Vines were propagated under unfavourable conditions. The workmen were not out of the house till April (last year) was considerably advanced, and the best place I had to strike the eyes was in a frame across the hot-water pipes before the roof was on the house. Now, supposing "J. S. W." to be a greater enthusiast than myself about the extension system, he would not, I believe, recommend leaving growth where there could be the slightest doubt about its perfect maturity. Give me thoroughly ripened wood on which the growths have been kept pinched the same way as for pot Vines, and I would as soon leave 20 feet as I would 1 foot.—WM. TAYLOR.

HALLAMSHIRE FLORAL AND HORTICULTURAL SOCIETY.

THE eighteenth annual Show of this Society was held on the 17th inst., in a field lent for the purpose by C. H. Firth, Esq., the President, at Ranmoor, Sheffield. The weather was all that could be desired and the Show was undoubtedly a financial success, as it may also be considered a success as a high-class exhibition. The exhibits well filled two large tents, one being occupied by the open and gentlemen's gardeners' classes, the other by amateurs and cottagers, who at this Show are always very strongly represented. The President kindly threw open his beautiful grounds and conservatories at Riverdale to the people visiting the Show, which added much to the attractions, and caused the gate money to flow fast and freely into the Society's coffers.

In the gentlemen's gardeners' tent there was a very good display of well-grown specimen stove and greenhouse plants, the principal prizetakers for which were Mr. T. Shelley, gardener to Mrs. Hobson, Burnt Stones, Sandgate; Mr. T. Fogg, gardener to Mrs. Wilson, Lapton Hall; and Mr. Sheridan, gardener to Mrs. Harman, Ranfall, Ranmoor. The first prize for six plants was well taken by Mr. T. Shelley with beautifully fresh and finished specimens of *Miltonia spectabilis*, 4 feet across and full of bloom; *Ixora coccinea superba*, very fine; *Crotons undulatus* and *variegatus*, *Stephanotis floribunda*, and *Allamanda Hendersoni*. The same exhibitor was also first with six exotic Ferns, all splendidly grown specimens, one of which, *Davallia Mooreana*, was a magnificent example 6 feet across. Mr. T. Fogg was second with very good examples of stove and greenhouse plants, having fine examples of *Bougainvillea glabra*, *Stephanotis*, and *Dipladenia Brearleyana*, and he also secured first prizes in the classes for Fuchsias, Coleus, and Zonal Pelargoniums, in each of which he showed finely finished specimens.

In the amateurs' tent the most noteworthy exhibits in the classes for plants in pots were the British Ferns. These plants are cultivated in a really first-class manner by numerous amateurs in and around Sheffield, inasmuch that I do not know of any other town or district in which they are equally so; and much of this is, I think, due to the example set for many years past by an enthusiastic and skilful cultivator. Mr. John Eadon, an occasional contributor to the Journal on the subject, and who was for many years a very active and useful member of the committee and large exhibitor at the shows of the Hallamshire Society. The principal prizetakers on this occasion were Messrs. R. Middleton, T. Marples, T. Froggat, and W. Smith.

Vegetables were shown in large numbers, but were not considered to be quite equal in quality to the exhibits of last year, owing to the long-continued dry weather. This was especially noticeable in the classes for Potatoes, which were generally inferior both in size and appearance to those shown last year.

Fruit was very well represented, Grapes, Peaches, and Nectarines being shown by several exhibitors of excellent quality, and Melons especially being very fine and numerous.

Cut Roses were shown in extra fine condition by R. Proctor, nurseryman, Chesterfield, and Duncan Gilmour, Esq., Sandgate. A bloom of A. K. Williams in the stand of the former was the finest which has been seen at any show in the district this season, and will scarcely have been surpassed at any of the National Rose Society's shows.

Capital groups of choice plants not for competition were exhibited by Messrs. Fisher, Son, & Sibray, Handsworth Nurseries, and by Mr. B. Crossland, Richmond Nurseries.

AVERAGE TEMPERATURES.

ONE of your readers writes, with reference to my remark that the temperature of the week ending August 15th was near the average, that "It is cold comfort, when we are suffering from frigidity, to be told we are enjoying the average temperature," and then he adds that he thinks that it will be of interest to give the difference between this August and last.

With your permission I will give two little tables, which will show the exact state of the case.

MAXIMUM IN SHADE.					
August.	Average.	1882.	1883.	1884.	1885.
1st week.....	72.0	74.5	72.4	79.7	70.7
2nd ".....	71.5	73.9	69.7	81.2	71.3
3rd ".....	70.8	70.6	74.9	79.3	70.0
4th ".....	70.0	67.7	77.3	68.6	—

MINIMUM IN SHADE.					
August.	Average.	1882.	1883.	1884.	1885.
1st week.....	53.8	53.0	53.2	53.5	52.5
2nd ".....	53.5	53.1	53.9	58.5	51.5
3rd ".....	52.8	56.4	54.3	52.9	50.8
4th ".....	52.2	50.8	53.1	52.4	—

This shows that the weeks have been, as I said, near the average (1° or 2° below it), and it also shows that 1884 was as I described it in three successive weeks—"Glorious summer weather," "Another week of glorious summer weather," and "The fine summer weather which had prevailed since the beginning of the month lasted through this week, but it was not quite so hot, the temperature being about 3° below that of the preceding week, though still considerably above the average."

My correspondent seems to have forgotten that an average, to be good for anything, must include a long series, not merely a few.—G. J. S.

CIRENCESTER.

AUGUST 20TH.

THE annual Exhibition of the Cirencester Horticultural Society was, by the kind permission of T. W. C. Master, Esq., held on the date named in the Abbey grounds, situated but a short distance from the centre of the town. The Abbey, dedicated to St. Mary, was founded by King Henry I., upon the abolition of the collegiate church that existed long before the Norman Conquest; but this, in its turn, suffered demolition. There is, however, almost overshadowing a portion of the grounds, the splendid edifice of the Church of St. John the Evangelist, with its handsomely proportioned, embattled, and pinnacled tower 134 feet high, from the top of which, on such a day as this, a view of the surrounding country excites a sense of admiration, the recollection of which cannot but be treasured, more especially that of Oakley Park, the seat of the Right Hon. the Earl Bathurst. The poet Pope was among the celebrities who enjoyed the hospitalities of Allan Lord Bathurst, to whom he dedicated his third epistle of "Moral Essays," commencing "Who shall decide when doctors disagree?" and there is in one of the rides in the park a stone structure designated Pope's Seat, besides many other objects of interest that may be seen by visitors, the noble owner of this magnificent park allowing it to be open to the public.

The schedule of the Society does not comprise a class open to all, consequently growers within an easy distance of Cirencester ("Our town of Cirencester in Gloucestershire."—King Richard II., act 5, scene vi.), who are famed for their stove and greenhouse plants, are not attracted to the capital of the Cotswolds as they might otherwise be. Nevertheless, the exhibits in many of the classes were of a high order of merit. The productions were exhibited in two large marquees, the largest measuring 130 feet by 60 feet, on the central stage of which were arranged some of the most noteworthy of the exhibits.

In the amateurs' class for a collection of plants grouped for effect, the first prize was awarded to the Misses Brown, Further Barton, the second position being gained by Mr. James Taylor, Rendcombe Park. For six distinct varieties of stove and greenhouse plants in bloom the same exhibitors succeeded in taking the prizes in the same order. In the premier

exhibit the plants, with the exception of *Statice profusa*, were remarkable well grown. These were, *Allamanda grandiflora*, *A. nobilis*, *Vinca oculata*, *Cassia corymbosa*, and *Dipladenia amabilis*, and in the latter were very fine specimens of *Allamanda nobilis*, *Bougainvillea glabra*, *Vinca alba*, and three *Ixoras*, the third prize going to H. Van Notten Pole, Esq., Watermoor House. For six ornamental-foliaged plants, *Begonias* and *Coleus* excluded, Mr. James Taylor was placed first with a splendid *Cycas revoluta* and fine specimens of *Miranda Lindenii*, *Croton Weismanni*, *C. interruptus*, *C. pictus*, and *Anthurium crystallinum*. In the second prize collection of the Misses Brown were fine specimens of *Cissus discolor*, *Caladium Prince Albert Edward*, and *Cycas revoluta*. Major Chester Master, M.P., Stratton House, was third, amongst his best specimens being a finely coloured *Dracena McArthurii*, *Alocasia metallica*, and well-grown plants of *Croton pictus* and *C. Weismanni*.

For a collection of exotic Ferns, Mr. James Taylor occupied the premier position, and his exhibit comprised some remarkably fine specimens, particularly those of *Davallia Mooreana*, *Dicksonia antarctica*, *Blechnum corcovadense*, *Adiantum trapeziforme*, *A. gracillimum*, and *Neottopteris nidus* avis. The second prize was taken by H. Van Notten Pole, Esq., who staged fine plants of *Davallia canariense*, *Adiantum farleyense*, *A. concinnum latum*, *A. Veitchii*, *A. trapeziforme*, *A. gracillimum*, and *Lomaria gibba*, while the third prize was taken by the Misses Brown, in whose collection there was a well-grown specimen of *Nephrolepis Duffii*, as well as good examples of *Cyathea dealbata* and *Adiantum farleyense*. The class for British Ferns was well contested, the collections embracing some of the best forms of our indigenous Filices, but the manner in which they were staged easily admitted of further improvement. Mr. W. Miller was awarded the first prize, the Misses Brown being a good second, and Mr. James Creese was placed third. In the class for six Zonal Pelargoniums, very creditably grown plants were staged of Ferdinand de Lesseps, Mrs. Wm. Paul, L. Grand, Emile Lican, Elegance, and Vesuvius, the prizes going to the Misses Brown and H. Van Notten Pole, Esq., in the order named. For six tricolor Pelargoniums, the schedule, it might appear, designedly discourages the cultivation of this class; however, there was a collection of six varieties staged by Major Chester Master, M.P., which was justly awarded the first prize. The classes for Fuchsias were both represented by specimens that reflected much credit on the growers of them, they being far above the average merit of plants generally exhibited at provincial shows. In both classes the successful exhibitors were the same, and the awards were in the same order, the first prizes being won by Major Chester Master, M.P., second honours going to the Misses Brown. For Gesneriaceous plants, no number being stipulated, the first prize was awarded to H. J. Elwes, Esq., Preston House, for six Balsams the Misses Brown were first, and H. Van Notten Pole, Esq., second. For six *Begonias* in flower the same competitors occupied the positions as in the former, and the Misses Brown were again placed first for six *Coleus*, while Major Chester Master, M.P., was second. For Cockscombs, six plants, T. W. C. Master, Esq., The Abbey, was first, H. Van Notten Pole, Esq., second, and the Misses Brown third. For a specimen stove or greenhouse plant in bloom the Misses Brown secured the first prize, exhibiting

One of the most interesting plants in the Show was *Peristeria elata*—the "Dove Plant"—introduced into this country from the neighbourhood of Panama in 1826. The plant in question bore a tall spike, on which there were eight expanded, peculiarly fragrant, waxy-white flowers, the columns of which, bearing a resemblance to a miniature dove, suggested to the inhabitants the name of "*El Spirito Santo*," (doubtless through the same religious feelings as obtained for the *Passiflora* the name of Passion Flower), under which name it was first imported. In this class H. J. Elwes, Esq., was second with an exceedingly well-flowered plant of *Hoya bella*, and Mr. James Taylor was third with *Bougainvillea glabra*. For three hardy plants grown in pots H. J. Elwes, Esq., was first, H. Van Notten Pole, Esq., second, and T. W. C. Master, Esq., third. The collections of cut blooms of Pelargoniums, Verbenas, Carnations, and Asters were fairly well represented, but Roses and Dahlias were meagre. The bouquets to be competed for by ladies as well as the epergnes of flowers did not present the artistic finish that we are accustomed to see. Wild flowers arranged in vases or baskets for effect were fairly good, as were those of stove and greenhouse plants. For cut flowers of hardy herbaceous plants H. J. Elwes, Esq., secured the first prize. Amongst his most noteworthy specimens were *Veratrum nigrum*, *Sparaxis pulcherrima*, *Gladiolus draccephalus*, *G. Lemoinei*, *Allium Wallichii*, a yellow form of *Verbascum phoenicum*, and *Alstromeria chilensis*. The second prize was awarded to T. W. C. Master, Esq. J. H. Elwes, Esq., also obtained the first prize for new, rare, or interesting plants, the most noticeable one being that of *Darlingtonia californica*.

Fruit and vegetables were of a high order of merit, especially those of Grapes, Melons, Peaches, Apricots, Plums, and Red Currants, the three bunches of Madresfield Court Grapes exhibited by Sir T. Bazley being extraordinarily fine, the berries being very large and well coloured. The most noticeable of the vegetables were those of Beet, autumn-sown Onions, Potatoes, Carrots, Red Cabbage (very fine), Kidney Beans, and Vegetable Marrows.

In the cottagers' division the quality of the exhibits generally was surprisingly good. There were also staged by Messrs. Jno. Jefferies & Son, not for competition, a fine collection of Tuberosus *Begonias*, comprising about forty varieties, three stands of cut Roses, in which were fine blooms of François Michelin, Alfred Colomb, Magna Charta, A. K. Williams, Mrs. Jowitt, Charles Darwin, Madame Eugène Verdier, Dr. Andry, Maréchal Niel, and Madame Victor Verdier. The same firm also exhibited a number of groups of *Gladioli*, stands of white Carnations, the beautiful *Tigridia grandiflora alba*, and an effectively arranged stand of eighteen bunches of hardy perennial flowers from their Cirencester nurseries.—I. B. E.

AMONGST THE NOVELTIES.

NOVELTIES unfortunately are very attractive to me, and the consequence is that I often lay out money in them which would have been far better spent on sterling old standard varieties. "Nothing venture nothing win" applies to purchasers of new vegetables as well as to other

matters, and if we never tried we should never know, so I expect I shall go on in the same way, trusting to light on a treasure now and again to recompense me for failures. This season has been a very trying one for my garden, for my soil is poor and shallow, on gravel, and situated in the highest part of Essex. If vegetables have stood this season fairly in my garden I think they must be good. However, here goes for the results of my trials. Mr. Editor will cut me short if I attempt too much, so I will begin alphabetically, leaving over half for another issue.

Broad Beans.—King's Essex Wonder Longpod I found inferior to several other varieties. John Harrison, Prolific, quality good, but pods not long enough for exhibition. Nettlefield's Prize, a tall very productive variety of good quality. Weh's Mammoth heats them all in every respect.

Dwarf Beans.—Ne Plus Ultra I find early, very productive, and good. I can strongly recommend it as a first early, and the Monster Negro Longpod is a first-rate one to follow, bearing a large crop of tender and very long pods.

Runner Beans.—Whether I have the true variety or not seems doubtful to me, because after seeing it so highly spoken of I hardly expected to find it (as I have it) no whit better or longer podded than the old Scarlet.

Beet.—Goldie's Superb Black. I like the look of it very well, but have not tried it yet. Broccoli and Brussels Sprouts will have their turn later on, also Cabbage.

Chou de Burghley I am much taken with when planted late, so that it comes in just before spring Cabbage. Its Marrow-like flavour is unique. It requires plenty of water in the pot when cooking, and if this is not observed it may taste something strong, like many other vegetables under the same treatment.

Carrots.—Stuart & Meins' Early Exhibition and another early variety of Messrs. Biddle's I tried, of which the former was preferable, but Early Nantes when true is far better.

Cauliflower.—Snowball I found early, white as snow, and of first-class quality.

Cucumbers.—Purley Park Hero I think very highly of. It is very productive, handsome in appearance, and of very delicate flavour. Empress of India I found a rather shy fruiter, but the quality was good.

Onions.—Golden Rocca and Queen, autumn-sown, did well, of which the latter came in early, having bulbs weighing over half a pound each on the average. The young ducks found these Onions very useful. The Roccas are very good, and I am pleased with them. Cranston's Excelsior, Rowsham Hero, Lancashire Prize, and some of Gilbert's strain were spring-sown. I find the first and last the best, Excelsior being a globe and Gilbert's a flat. Both are very good, and I look forward to trying them in a better season. Rowsham Hero I am disappointed in, but perhaps another season it may do better. So far it looks no better than Lancashire Prize, and that is of no account.

My favourites, Peas and Potatoes, I will leave to another time if the Editor will give me room. I look forward to perusing the remarks of some far more able pen on the novelties they have tried this season. Let us live and learn, and above all let us try to distribute the knowledge we have attained by sometimes sad experience.—H. S. EASTY.

WESTON-SUPER-MARE SHOW.

THE thirteenth annual Exhibition of this Society was generally considered one of the most successful yet held, and in some respects was superior to that just previously held at Taunton. The arrangements were perfect, and Mr. F. T. Perrett, the new Secretary, is to be congratulated upon the success attending his labours. Mr. John Matthews, of pottery fame, takes great interest in the Society, and is a most genial and hospitable chairman. Fine weather prevailing, the attendance of visitors was most satisfactory, and it is to be hoped a good balance at the bank is the result.

Liberal prizes were offered for twelve stove or greenhouse flowering and fine-foliaged plants, and with these Mr. G. Lock, gardener to W. B. Cleave, Esq., Crediton, was easily first, his collection including fine healthy specimens of *Kentia Fosteriana*, *Areca lutescens*, *Kentia Belmoreana*, *Croton Disraeli*, a grand plant of *Erica Marnockiana*, *E. æmula*, *Dipladenia Brearleyana*, *Ixora Duffii*, *Eucharis amazonica*, all in good condition. Mr. J. Cypher, Cheltenham, was a rather poor second, his most noteworthy specimens being of *Erica ampullacea*, *Anthurium Andreanum*, and *Croton majesticus*. Mr. J. F. Mould, Pewsey, was a good third. The best six flowering plants were staged by Mr. J. Mould, who had fresh, medium-sized, well-flowered examples of *Dipladenia amabilis*, *Erica Austiniana*, *Ixora reginae*, *Bougainvillea glabra*, *Erica Marnockiana*, and *Clerodendron Balfourianum*. Mr. Cypher was placed second with a fairly good collection, but not up to his usual form. Mr. Lock was also first for six fine-foliaged plants, having immense healthy specimens of *Cycas revoluta*, *Latania borbonica*, *Areca Verschaffeltii*, *Gleichenia rupestris glauca*, *Croton Williamsii*, and an *Alocasia*. Mr. Cypher was a good second. The best six exotic Ferns were staged by Mr. Lock, these including very large specimens of *Davallia Mooreana*, *D. polyantha*, and *Gleichenia rupestris*. Mr. W. Brooks was second, and Mr. J. E. Cole third, each having very creditable groups. In the class for six *Adiantums* Mr. J. F. Taylor won the first prize, having medium-sized and very healthy specimens of *A. tenerum*, *A. cuneatum*, *A. cardiophyllum*, *A. gracillimum*, *A. farleyense*, and *A. amabile*. Mr. W. Rye, gardener to J. Derham, Esq., Snayd Park, Bristol, was a good second, his best plants being of *A. cardiophyllum*, and *A. Farleyense*, and Mr. J. P. Cassell was third. Zonal Pelargoniums were very well shown by Mr. W. Adams, gardener to W. Smith, Esq., the varieties being Emily, Mucedra, Ellen, New Life, Arabella, and Mrs. Strachey. There were also classes provided for Fuchsias, Lillies, Clematis, Coleus, Begonias, Balsams, Achimenes, Cockscombs, and Lycopodiums, and all were fairly well shown, the most successful exhibitors

being Messrs. W. Brookes, W. Ash, J. E. Cole, J. P. Cassell, and F. W. S. Wicksteed.

A second large tent was devoted to the productions of amateurs or their gardeners, and here again the competition was remarkably good. With six flowering plants Mr. Lock took the lead, these consisting of medium-sized fresh examples of *Ixora Williamsii*, *Dipladenia Brearleyana*, *Allamanda grandiflora*, *Erica tricolor Wilsonii*, *E. Eweriana superba*, and *Clerodendron Balfourianum*. Mr. W. Rye was a good second, his collection including a good *Stephanotis floribunda* and *Ixora Williamsii*, and the third prize was won by Mr. W. Hughes, gardener to H. Pethick, Esq. Mr. Lock was again first with six fine-foliaged plants, these including a handsome specimen of *Croton Warreni*, and a large *G. ichenia spelunca*. Mr. W. Rye followed very closely, his fine even group being somewhat marred by the similarity of the *Crotons*, variegatus, *Weismanni*, and *pictus*, the remainder consisting of large, very healthy specimens of *Areca sapida*, *Latania borbonica*, and *Dæmonorops palembanica*. With four *Adiantums* Mr. Lock was easily first, and Mr. C. Holland, gardener to W. Ash, Esq., a creditable second. Several good groups of *Coleus* were arranged, the first prize going to Mr. W. Andrews, gardener to W. Smith, Esq., who had fine plants of *Butterfly*, *Sensation*, *Weston Favourite*, and *Weston Sunset*. *Balsams*, *Fuchsias*, *Gloxinias*, *Begonias*, and *Zonal Pelargoniums* were also shown creditably by various exhibitors.

Cut flowers, including *Roses*, *Dahlias*, and *Gladioli*, were shown in greater numbers and excellence than might have been anticipated, and there were a considerable number of very tastefully arranged vases and bouquets. Mr. E. Miller, gardener to F. Tagart, Esq., Old Sneyd Park, Bristol, was first in the open class for cut flowers, the collection being noteworthy both on account of the choiceness of the flowers and also the tasteful manner in which they were set up. Messrs. Cypher, and Perkins & Son, Coventry, were the most successful exhibitors of bouquets, the former, as usual, occupying first position, the quality of the flowers, as well as their arrangement, being of the best description. The first prize for cut spikes of *Gladioli* was easily won by Mr. Dobree, Wellington, some of his best sorts being *Bushman*, *Flamboyant*, *King of Scarlets*, *Celestine*, *Prosper Langier*, *General Chasse*, *Eugene Scribe*, *Leda*, *Helen Masterman*, and *Belzoni*. Mr. W. Brooks, Weston-super-Mare, also staged creditably, and was awarded the second prize. *Hollyhocks* were well shown by Messrs. W. J. Burgess and W. Brooks; *Asters* by A. Walters, Bath; single *Dahlias* by T. Carr, Truckle, and A. Walters; double *Dahlias* by A. Hill; and S. Budd, Esq., was the principal prizewinner with *Roses*. Some of the best of the latter were *La France*, *Alba rosea*, *Marie Baumann*, *Captain Christy*, *Louis Van Houtte*, *Bouquet d'Or*, *Mons. E. Y. Teas*, *Marie Van Houtte*, *Queen of Queens*, and A. Colomb. Messrs. Parker & Sons, Bristol, received the second prize for *Roses* for a meritorious stand. The latter firm also exhibited a stand of a charming white bedding *Viola*, this variety possessing the merit of being sweet-scented.

Cut flowers were also well shown in the amateurs' tent. Mr. Rye was first with twelve varieties of choice cut flowers, and Mr. E. S. Cole, Sneyd Park, Bristol, displayed great taste in his first-prize device, combining fruit and flowers. Mr. M. Hookings was first in another good class for a floral device, the *Bristolians* generally excelling in this section. With twelve varieties of *Roses* Mr. S. P. Budd was easily first, his stand including excellent blooms of A. K. Williams, Duke of Wellington, François Michelon, Duchess of Bedford, Magna Charta, Arthur Dickson, and Comte de Raimbaud. Mrs. J. Burgess was a good second with *Roses*, and Mr. Dobree again first with *Gladioli*.

The display of choice fruit was fully equal to former occasions, but there was rather less hardy fruit than usual. With eight dishes of fruit Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, was first, staging a collection very similar to that he had at Taunton; and Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, followed closely, his collection including good Black Hamburg Grapes, Black Tartarian Cherries, High-cross Hybrid Melon, Grosse Mignonne Peaches, and Moorpark Apricots. The third prize went to Mr. W. Rye, whose best dishes were fairly good Muscat of Alexandria Grapes, Hero of Lockinge Melon, and a very fine dish of Ford's Seedling Peach. Muscat of Alexandria Grapes were not represented in great quantities, and the only really well finished examples were shown by Mr. W. K. Wait, the second prize going to Mr. J. Marshall, gardener to M. Whitwell, Esq. In the any other white class, Mr. A. Young, Clifton, was placed first for three beautifully finished bunches of Buckland Sweetwater; Mr. Miller following with fine bunches of a seedling Grape bearing a strong resemblance to Canon Hall Muscat, and Mr. J. Marshall was third with good Buckland Sweetwater. There were fifteen entries in the class for Black Hamburg, Mr. Iggulden taking the first prize for compact, well finished bunches, the second prize going to Mr. J. Ellicott, gardener to W. Tugwell, Esq., Bath, and the third to Mr. A. Young, each having good examples of this popular sort.

There were fewer exhibits in the class for any other black variety, and here Mr. W. Nash took the lead with three grandly finished bunches of Black Alicante, Mr. E. T. Hall following with fairly good Madresfield Court, while the third prize went to Mr. Sweeting, Sneyd Park, Bristol, who staged Venn's Seedling in fairly good condition, but the examples were by no means so good as those with which he caused a sensation the first time he exhibited this presumably distinct sort of his own raising. Melons were shown in good numbers, and some were very good. Mr. Rye was first in the class for green-fleshed varieties with Hero of Lockinge, and Mr. Miller was first in the class for scarlet-flesh varieties with Blenheim Orange, the fruit being of excellent quality in both instances. Peaches and Nectarines were very fine, but the Judges rather unduly favoured those of best appearance. For instance, a handsome and somewhat small dish of Crispin Galande, staged by the gardener to Mrs. Temperley, were placed before a very fine dish of Grosse Mignonne exhibited by Mr. W. Daffurn, gardener to Mrs. Walker; and a handsome dish of Elruge staged by Mr. Daffurn was put before a grand dish of Pitmaston Orange staged by Mr. Wollen, Wedmore. Figs were well shown by Messrs. J. Matthews, gardener to T. T. Knypton, Esq., an W. Fear; and Apricots by W. Fear and A. Hill, while the classes for Cherries, Pears, Plums, and Apples were all fairly well filled.

Vegetables were not so plentiful as usual, but the quality was remarkably good. The best collection of eight dishes was put up by Mr. Tilley, gardener to Colonel Cotgrave, and comprised good examples of Sutton's

Perfection Tomatoes, International Kidney Potatoes, Autumn Giant Cauli-flowers, Snowball Turnips, Sulham Prize Celery, Lemon Rocca Onion, Intermediate Carrot, and Scarlet Runner Beans. J. Law, Esq., was a good second, and Mr. J. Chaff, gardener to T. Chamberlain, Esq., third. Mr. Rye had the best Tomatoes, a fine dish of Hackwood Park Prolific; and Mr. J. H. Parsons was first in the class for Cucumbers with a fine brace of Webb's Perpetual Bearer. The cottagers also showed a lot of good vegetables, fruit and flowers.

Mr. J. Matthews, the Royal Pottery, arranged an extensive assortment of terra cotta statuary, vases, and other useful articles, which for excellence of design, perfection of finish, and quality of material, could not well be surpassed.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 25TH.

THE exhibits in competition for the prizes offered for cottagers' and artisans' garden produce formed the greater portion of the display at this meeting, and constituted a really wonderful exhibition of vegetables. There were between 600 and 700 entries, and in several classes the number of competitors was astonishing, as for instance in the class for a collection of six dishes of vegetables, of which there were no less than thirty-two exhibitors, and the Potatoes were also surprisingly numerous. The whole of a table extending down the centre of the conservatory and some portions of the side tables were devoted to these contributions, which comprised, in addition to those named, Beans, Peas, Onions, Beet, Turnips, Vegetable Marrows, Cucumbers, Tomatoes, Herbs, Apples, Gooseberries, Currants, and a few other fruits.

Gardeners had been invited to send dishes of Plums to this meeting for comparison and re-naming where necessary, but the only response were those sent from Mr. Smee's garden, together with the collections from Messrs. Rivers and the Society's Gardens at Chiswick. Messrs. Bunyard's handsome Apples were, however, much admired amongst the exhibits before the Fruit Committee.

The floral groups were not quite so numerous as on some previous occasions, but Mr. T. S. Ware again contributed liberally from his extensive collection of herbaceous plants, and had some choice arrangements of Lilies and Dahlias. Messrs. Kelway & Son similarly furnished a bright and important group of *Gladioli*, including 140 spikes of nearly as many varieties. Several fine Orchids added interest to the meeting, and one very remarkable incident occurred, the new *Angraecum Leoni* being shown in flower by five exhibitors, to each of whom a first-class certificate was awarded—a memorable event in the history of certificated plants, for probably a similar occurrence has never taken place before.

FRUIT COMMITTEE.—Present, T. F. Rivers, Esq., in the chair, Harrison Weir, G. Bunyard, J. Willard, J. Ellam, J. Roberts, Dr. R. Hogg, Wm. Paul, R. D. Blackmore, J. Woodbridge, G. T. Miles, and F. R. Rutland. Mr. Ward, the Gardens, Longford Castle, Salisbury, sent three splendid bunches of Buckland Sweetwater Grapes, to which the large bronze Banksian medal was awarded. Mr. G. Cummins, the Gardens, The Grange, Wallington, sent six dishes of Plums, two of Apples, and two Pears. Mr. P. Robertson, the Gardens, Hartrigg, Jedburgh, sent a branch of a seedling Red Currant called Mrs. Gladstone. It was a very fine Currant, but not to be distinguished from others in cultivation. Mr. Humphrey, the Gardens, Nash Court, Faversham, sent a very handsome seedling Melon, which, when cut, was found to be inferior in quality. Mr. Hudson, the Gardens, Gunnersbury Park, also sent a seedling Melon which was not of good flavour. Mr. G. Bunyard, the Nurseries, Maidstone, exhibited fruit of Bijou, Triomphe de Vienne, and Beurré Giffard Pears. They had been grown under glass, and therefore the flavour was not well developed. Triomphe de Vienne was quite rotten at the core. A letter of thanks was awarded. Messrs. Kelway and Son, Langport, sent three Cucumbers—Hero of Langport, Melton, and Conqueror—to which a cultural commendation was awarded. Messrs. W. Paul & Son, Waltham Cross, sent a dish of Beurré Giffard Pear, which was in excellent condition, and also Beacon and Peach Pears, to which a letter of thanks was awarded. Mr. William Earley of Ilford sent fruit of *Prunus domestica Myrobalana*, the yellow-fruited variety.

Mr. G. F. Wilson of Weybridge Heath sent a dish of Transparent Gage Plum, beautifully coloured and highly ripened, to which a cultural commendation was awarded. Messrs. T. Rivers & Son, Sawbridgeworth, exhibited a collection of twenty dishes of fruit, chiefly Plums, many of which were seedlings of their own raising; to this the large bronze Banksian medal was awarded. Mr. George Bunyard of Maidstone sent sixty-five dishes of fruit, to which a silver Banksian medal was awarded. Thirty dishes of Plums were sent from Chiswick, representing as many varieties, some of the most remarkable being Reine Claude d'Oullins, Belgian Purple, Bradshaw, Diamond, Dammas Musque, Gisborne's, Victoria, and Sharpe's Superior, very prolific.

FLORAL COMMITTEE.—Present John Fraser, Esq., in the chair, Shirley Hibberd, H. Cannell, E. Hill, H. Turner, F. R. Kinghorn, W. Wilks, W. Bealby, Maxwell T. Masters, J. Child, J. James, H. Bennett, G. F. Wilson, G. Duffield, J. Noble, Thomas Baines, J. Dominy, H. M. Pollett, H. Williams, J. Hudson, James O'Brien, and Amos Perry.

The exhibits before this Committee were not very numerous, but, as will be seen from the list of plants certificated, they comprised several of much interest. Some stands of Dahlias were shown by Messrs. Keynes, Williams and Co., Salisbury; C. Turner, Slough; Rawlings Brothers, Romford; and T. S. Ware, Tottenham, representing the best of the early varieties in good condition. G. F. Wilson, Esq., Weybridge, exhibited a stem of *Lilium auratum* with twenty blooms from a plant 8 to 9 feet high planted in 1881, for which a vote of thanks was accorded. *Lilium superbum rubro-striatum* is a pretty variety with regularly striped flowers. *Lilium tigrinum splendens*, a handsome variety, and *Gentiana asclepiadea* were also well shown by the same gentleman. Messrs. H. Cannell & Sons, Swanley, sent a fine-foliage Begonia with silvery leaves, red in the centre, edged with green, spotted with white. Lady Howard de Walden, The Mote, Maidstone, sent a fine double yellow Tuberous Begonia bearing her name. Mr. Owen of Maidenhead also had a plant of a double yellow Begonia named *Madéchal Niel*, and a single rose-coloured one named *Marquis of Lorne*, both good. M. J. Linden, Ghent, sent a plant of a *Cattleya* named *Magenta*, which was not considered

distinct enough to merit an award. Mr. W. Bull, Chelsea, had some fine Caladiums, Ibis Rose and Perle du Bresil with that certificated being the best. A vote of thanks was also accorded for Dion edule lanatum, a woolly-leaved form, which, we believe, has been previously honoured. Cattleya crispa venusta, from the same establishment, with white flowers and a crimson fringed lip, was also noteworthy. Messrs. J. Veitch & Sons, Chelsea, had a pretty collection of Salpiglossis in many varieties, crimson, purple, yellow, and parti-coloured. They also had several handsome Gladioli of the Lemoinei type, which have been previously noted, and plants of their magnificent Rhododendrons Dyak and Gloria Mundi, the former orange and the latter rosy salmon.

A silver-gilt Banksian medal was awarded to Messrs. Kelway & Sons, Langport, for their grand collection of 140 spikes of Gladioli, most varied in colours, and representing the most distinct of the very numerous varieties now grown. Mr. T. S. Ware, Tottenham, was adjudged a similar award for his superb and extensive collections of hardy flowers which invariably attract a crowd of admirers. The New Plant and Bulb Company were awarded a bronze Banksian medal for a large collection of Liliun auratum in many varieties, arranged with a few Orchids and other plants.

PLANTS CERTIFICATED.

Dahlia Mrs. John Walker (Rawlings Bros.).—A handsome, compact, well-built bloom, the florets white tipped with purple; distinct and attractive.

Androsace lanuginosa Leichtlini (Max Leichtlin).—A white variety of this well-known plant, the flowers having a red centre; pretty, but not more so than the ordinary type.

Dahlia Germania nova (H. Cannell & Sons).—An exceedingly distinct Dahlia with acute closely packed florets of a bright rose colour, the blooms of medium size and neatly formed.

Lælia elegans Littleana (H. Little, Esq.).—A handsome variety, suggestive of *L. elegans* Turneri; sepals and petals tinted with purple to the base, the lip being an intensely rich crimson, except in the throat, which is pure white, contrasting well with the deep neighbouring colour.

Angræcum Leoni.—Certificates were awarded for this plant to Sir Trevor Lawrence, Bart., M.P.; Mr. W. Bull, Chelsea; R. H. Measures, Esq., The Woodlands, Streatham; C. Dorman, Esq., The Firs, Laurie Park, Sydenham; and W. Vanner, Esq., Camden Wood, Chislehurst. It is a pretty species, but has been somewhat over-estimated, and its comparison to *A. sesquipedale* is certainly not justified. The leaves are thick, curved, and placed vertically. The flowers are pure white, 2½ inches in diameter, the lip 1½ inch long, and three-quarters of an inch wide, of an ovate form, the sepals and petals being narrow, and the greenish-white spur several inches long. The plants had two or three spurs of four to five flowers each clustered rather closely on the foliage.

Gastranema hybrida (Sir Trevor Lawrence, Bart., M.P.).—An extremely interesting plant, a hybrid between *G. sanguinea flammea* and *Vallota purpurea*, with narrow deep green leaves, and flowers resembling the *Vallota* in form, but slightly smaller, and of a light orange-scarlet hue.

Blandfordia flammea (Sir Trevor Lawrence, Bart., M.P.).—A very handsome bulbous plant, with a head of twenty flowers and buds, the former bell-shaped 3 inches long, scarlet, with a yellow throat and green-tipped lobes.

Caladium Comtesse de Maille (W. Bull).—Leaves semi-transparent, with a green margin and red veins; a very pretty and delicate variety.

Odontoglossum Insleyi splendens (W. Bull).—Flower of great size, the sepals and petals brown, the lip yellow, spotted with bright red.

Rhododendron Pearl (J. Veitch & Sons).—A supposed hybrid between *R. Princess Royal* and *R. Aucklandi*, though the influence of the latter parent cannot be traced. It is, however, very distinct, with neat white and faintly rose-tinted flowers, with small closely set leaves.

Gladiolus Masque de Fer (J. Veitch & Sons).—One of the *G. Lemoinei* type, scarlet, with the two lower petals deep maroon. A distinct and handsome variety.

Lælia Sedeni (Baron Schröder).—A magnificent Orchid, with narrow crimson sepals and petals, the lip nearly 1½ inch broad, intense crimson, with a white throat. The colour of the lip is exceedingly rich, and renders it one of the best of its type.

Aqanisia cærulea (H. J. Buchan, Esq., Southampton).—A botanical certificate was awarded for this curious but not very attractive Orchid. The sepals and petals pale purplish, and curving over the hollowed purple-veined lip.

New Gladioli (Kelway & Son).—*Princess Olga*, flowers white, beautifully streaked with rose, large and borne in a massive spike; a grand variety. *Prince Albert Victor*, scarlet, with a white central blotch in the lower petals, spike very compact. *Viscount Cranbrook*, salmon scarlet, crimson throat, spike long and dense; very handsome. *Princess Irene*, flower large, white margined with rose, of fine substance, and borne in a noble spike; a lovely variety. *Sir Henry Drummond Wolff*, brilliant scarlet, with a crimson blotch in the lower petals; very effective. *Prince Henry*, purple streaked with white, and central blotch.

THE COTTAGERS' SHOW.—As the largest exhibition of the kind that the Royal Horticultural Society has yet held, this merits a word or two of notice. Between 600 and 700 entries were received in the thirty classes provided, and throughout the quality of the productions was highly creditable to the exhibitors. The collections of six kinds of vegetables were especially good, and that the competition was keen may be judged from the fact that thirty-two collections were staged, five prizes being awarded, two collections highly commended and two commended. The first-prize vegetables from Mr. C. Beckett, Tyler's Green, Penn. Bucks, were extremely good, and would not have disgraced a professional gardener. They included Excelsior Tomatoes, Woodstock Kidney Potatoes, Veitch's Autumn Giant Cauliflowers, Carter's Champion Beans, Long Red Surrey Carrots, and Giant Rocca Onions, all neatly arranged on dishes with Parsley. Potatoes were well shown, there being 112 entries in the four classes. Both Runner and Kidney Beans were also strongly represented, the former by thirty-six and the latter by twenty-four dishes. Onions were fine, Turnips, Carrots, Beet, Vegetable Marrows, and Tomatoes being equally deserving of commendation. Apples were mostly of fair size and numerous, Gooseberries being large, and Currants good. As a whole the Show was most satisfactory, and proved con-

clusively that the working classes are making substantial progress in the cultivation of the useful garden crops.

HARDY FRUIT GARDEN.

LATE SUMMER PRUNING.—Now is the time when much good or much harm may be done to fruit trees by pruning. Good, if we shorten the midsummer growth sufficiently to give free admission of light and air to the spurs and every part of the branches; harm, if we shorten so much as to induce basal buds to start into growth now when the time remaining during which growth can advance, is so short, that the full development of shoot and bud is impossible. In five weeks from this time October will be here; we may then expect a fall in temperature that will at once check growth. It requires very little calculation, therefore, to see that if by injudicious pruning now we induce buds to start into growth, that growth will prove abortive and worthless. Instead, therefore, of close pruning, leave the wood from 4 to 6 inches in length according as the buds are thick set or otherwise, and then while the outer buds start into growth, the inner or basal buds will become full and plump without bursting, so that we can prune down to them after the fall of the leaves, and so leave them in the best possible condition for an early strong growth in spring. At one time it was our practice at this season of the year to twist and bend down the midsummer growth to render the lower buds plump, and not to prune at all till winter; but the hanging shoots proved so serious an obstruction to the passage of light and air that shortening of the shoots was adopted with the best results. Why, when, and how to prune is not half so well understood as it ought to be. These hints apply solely to trees cultivated on the spur system, the free growth of orchard trees only requiring some slight regulation and thinning in winter. As we prune now it will be well to mark barren trees of gross rampant growth for root-pruning to be done in September, both to arrest the flow of sap as early as is safe, and to induce the roots to put forth some rootlets this autumn. It may safely be laid down that the best time for root-pruning is early in September, and there can be no reasonable objection to the pruning being thorough in its application to young trees, provided they are prevented by stays from becoming subsequently loosened in the soil. Old trees, on the contrary, should have only half the roots shortened this autumn, leaving the remainder for next year, but we must take especial care to go fully half way under the tree so as to sever tap roots running downwards into the subsoil. The length of roots left on the tree should be about 2 feet for young trees up to 6 feet for old trees according to size: the greater length being only necessary for very large old trees. After pruning we like to fill the trench with sound, rich, mellow loam for the young roots to lay hold of, and to give a top-dressing of rich manure from the stem outwards to the trench. Do not root-prune trees indiscriminately; it is to trees of rampant growth that we must apply it, fruit-bearing and not mere wood growth being our end and aim in the culture of fruit trees; and when we see a fruit tree with robust growth of branch and stem, sturdy, stout, and strong, yet bearing no fruit year after year, we know that there is also excessive vigour of root-growth, which must be checked if we would have fruit.

Fruit-growers generally have recently had a severe lesson about the importance of shelter for orchards and fruit gardens. High winds prevailed so generally just as the fruit was half grown, that even from Ireland came the sad plaint of the fruit being swept off every tree, and many a fruit-grower on this side the Irish Channel has repeated the cry. To plant standards at all is to run much risk of such losses, but to plant them in exposed situations adds considerably to the risk. To know how to plant and what to plant, we must live much among fruit trees during the season of growth, and we must be eager to learn and quick to apply the lessons of the seasons in our practice. Let no young man suppose that because it has been his privilege to serve for a time under some famous fruit-grower, and among a large collection of fruit trees, that he is proficient in fruit culture. If he is intelligent, earnest, teachable, and therefore humble, he may have gained much useful knowledge, but it is only the costly teaching of experience that can render him a past-master of the art—costly because of the penalty of some of the best years of our life which we have to pay for its acquisition.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early House*.—The trees in the early house have completed their growth, and the resting period may be said to extend through September, October, and November, though when very early forcing is practised the trees are started by the middle of November, therefore to give them the full benefit of the intervening ten weeks or so measures should be taken to keep them as cool as possible. If the trees are trained to trellises under fixed roofs all the doors and ventilators should be kept constantly open, but these forms of roofs are not suitable for early-forced trees, as the difficulty is to prevent premature development of the buds; hence if the roof-lights are fixed, and there is the least sign of the buds becoming too prominent, the removal of some of the squares from the central part of the roof will increase the current of air, and tend

greatly to reduce the temperature of the house. The removal of the lights for a time will arrest premature bud-development, and the exposure to dew and autumnal rains will benefit the foliage, whilst the roots will receive a more uniform moisture than is ever attained by artificial watering. When the leaves fall the final pruning should be done, but all weak and useless wood having been cut out immediately after the fruit was gathered the autumnal pruning will be of a very trifling character.

Second House.—The trees having been cleared of the fruit quite a month ago, as well as any weak and useless growths, they will now have the wood quite firm and the buds prominent. Ventilate freely both top and front, and with moveable roof-lights, which there ought to be in all fruit houses subjected to early forcing. These should be removed by the early part of September or during the first fortnight of that month, as exposure to night dews and autumnal rains is of great benefit to the trees. The trees will need an occasional syringing to keep the foliage clean and healthy, and there must not be any lack of moisture at the roots. In the case of vigorous trees it will be well to keep the wood rather thin, so as to secure its thorough ripening by the free admission of light and air.

Third House.—Trees that are forced so as to ripen their fruit from the middle of July onwards will now be cleared of the fruit, and when this takes place all useless wood should be cut out, and the growths if at all crowded thinned, leaving no more wood than will be required for next year's fruiting or for affording the needful extension of the trees. Thoroughly cleanse the trees of dust and insects by means of the garden engine, and if necessary apply an insecticide to keep red spider and scale in check if not to eradicate these pests, it being important that the foliage be kept clean and healthy to the last. If the trees are young and vigorous and the wood not ripening kindly close with sun heat early in the afternoon, running up to 85°, and towards evening commence ventilating for the night.

Watering Peach Trees in Houses.—An impression prevails that dryness at the roots hastens the ripening of the wood, but this seriously injures the trees; indeed, many fine trees have been irreparably damaged by withholding water, and more buds fall from this cause than any other. When the borders are properly made and drained there is scarcely any fear of over-watering, and in such, or indeed any, the soil should never be allowed to become dry, and the mulching should not be taken off until the time comes for the annual surface dressing of fresh compost. When the borders are badly drained the roots strike downward in search of moisture, and make late growths—a quantity of breastwood and soft growth—when they should be resting. When trees are in the latter condition careful lifting and relaying the roots in new soil resting on good drainage is the best and most profitable expedient. The proper time to operate on the roots is when the foliage shows signs of ripening, but before it falls from the trees.

Late Houses.—The fruit in these is more advanced for ripening, and will need free ventilation night and day, but syringing the trees should cease, though if the days are bright a moderate air moisture will be necessary for the benefit of the foliage. The borders should not be allowed to become dry. The growth of the latest varieties, such as Walhurton Admirable, Princess of Wales, Salwey, &c., will still be swelling, and if the present dry weather continue the trees will derive considerable benefit from the continued supplies of liquid manure and mulching. The wood in all late houses should be kept rather thin, so as to secure the solidification of the growths, and if the wood is not likely to ripen kindly gentle fire heat with a free circulation of air will be of great benefit and tend to improve the quality of the fruit as well as ripening the wood. Midseason varieties, however, will under the influence of a favourable autumn ripen the wood without fire heat.

MELONS.—The fine weather has been very favourable to Melons growing in unheated pits and frames, in which water henceforward should be used very sparingly; but should the plants be likely to require water give it before midday, or sufficiently early to allow the foliage to become dry before night, otherwise mildew will be likely to be troublesome, and canker will probably appear, for which a sharp look-out must be kept, and quicklime rubbed well into the affected parts upon its first appearance. Houses in which the fruit is ripening will need a free circulation of air, and if the weather prove cold and wet gentle fire heat will be necessary. Late plants will require attention in stopping, thinning, and tying the shoots, keeping them fairly thin to admit of light. Damping and watering must be regulated according to the weather and the condition of the plants. Fire heat will be necessary to prevent the temperature falling below 70° at night, and to keep it between that and 75° in the daytime. Expose the fruit as much as possible to the sun's rays.

THE BEE-KEEPER.

UNITING OR RETURNING SWARMS.

THE old-fashioned bee-keeper seems to have an instinctive dread of preventing an inordinate increase of his bees, even if he learns—as he often does, from the larger amount of honey obtained in the apiaries of his more advanced neighbours—that a far greater weight of honey can be accumulated by stocks that are allowed to follow their natural instinct by

swarming once, but are prevented from further weakening themselves. If the latter is permitted the bee-master cannot gain from the short honey glut of most counties so great a weight of honey as he would have been enabled to do if, content with a moderate increase only, he had returned or united to other hives his casts or second swarms. This would prevent the mother hive being reduced so seriously in strength by sending out a number of starveling swarms, which are of themselves unable to prepare a home against the coming winter season. They might, however, if two or more were united, or if each swarm after the first was returned to the mother hive, make the stock not only to gather a plenteous store, but to give a moderate surplus to the bee-keeper, and to remain a strong healthy colony, fit to brave the winter. Weak stocks in autumn are also constantly liable to the hosts of pilferers ever ready to rob a weakling hive of its unprotected stores.

There is no manipulation so simple as that of uniting swarms and stocks; but a very few minutes are needed to effect the union so beneficial to both the bees and their master. I remember Dr. Bevan gives three usual methods by which union has been attempted, and he himself adds a fourth. These are—"Fuming them, immersing them in water, and aspersing them with sugared or honeyed ale," and another by operating upon their fears." Imagine the poor bees immersed in water to effect a union, or put to sleep by nauseous fumes, or sprinkled with sugared ale! Possibly each method was successful, but the one which to me appears by far the simplest is perhaps related to the third and fourth methods of the good doctor. It matters little whether two stocks or two swarms, or a stock and a swarm, are to be operated on; it is equally successful in any case, under any circumstances, and as an additional recommendation to those who love simplicity it is quite unnecessary to seek an interview with her majesty the queen mother of the hive.

Suppose, then, a swarm has issued and been hived in straw skep, it should be placed as near as possible to the stock or swarm to which it is proposed to unite it, and there left till the evening. The only requisites to have at hand ready for the dusk are a cloth and a smoker and a little syrup scented with a few drops of peppermint with which to sprinkle the bees in order that the peculiar scent may be deadened, they being the more kindly and certainly received by the occupants of their future home. At dusk, then, spread the cloth before the hive with which it is desired to effect the union; not that there is any virtue in the cloth itself, but it prevents the bees from being entangled in the grass or any other refuse or herbage near the hive. Let some sticks be placed upon the cloth to prop the hive placed upon them up some 2 inches from the ground. After sending into the stock hive a few puffs of smoke and leaving the bees time to fill themselves, take up the hive containing the swarm, and with a "violent jerk" throw down all the bees upon the cloth; sprinkle them quickly with the scented syrup, and place over them the other stock, covering the whole to protect them from wet or wind. Leave them till early morning, when the now strengthened stock should be placed once more upon its old stand, in order that the bees flying early to the fields may not, missing their hive, fly away and die at the entrances to other hives. The above simple plan, then, carefully carried out, never fails to bring about the desired union without the loss of time, the loss of bees, or the trouble entailed by some of the more elaborate plans for effecting the same purpose, in which catching the queen and killing her generally holds a foremost position.

Let each one try for himself and see how simply the union may be effected, and he will in future never hesitate to unite whenever he thinks such union likely to benefit his bees. One word of warning, however, should be given, and that is, that if a second swarm be joined to a first it sometimes happens that the older queen succumbs to the attack of her more nimble rival; but as in such case the eggs only of a very few days are lost, and a young active queen takes

the place of her more aged predecessor, there is perhaps more gain than loss.

The plan of action when uniting two stocks is exactly similar, with the exception that one stock has first to be driven from its combs into an empty hive, the less time that elapses between the driving and uniting the more complete and certain will the success attending the operation be. To conclude, let me say that if it is preferred—and it is in many cases the wiser course—to simply return the second swarm, the plan of action is to hive the swarm in the usual manner, leaving it for a few hours, and then taking it and throwing it back upon the front of the hive from which it issued. This, too, rarely if ever fails; but if next day the swarm should issue again the same operation should be repeated, and the result will be that the desire of the bee-master will most certainly be attained. These hints are given at the suggestion of a bee-keeper who does not always succeed in effecting happy unions; but when he did attempt to unite according to his old plan there was often a massacre, ending in the almost total annihilation of the bees of both stocks. To some the plan here given may be of use, and if those who are already acquainted with good systems for effecting a like object look with contempt upon rules so often repeated and so well known to them, let them call to mind that when they were novices such hints were of good service to them in enabling them to become proficient in the art of bee-keeping. —FELIX.

FRAME HIVES v. SKEPS.

IN the Journal for July 30th "A Hallamshire Bee-keeper" makes the extraordinary statement that he would not simply give the skep a place in the apiary, but he would place it first. He then gives what he calls "a nut for advanced bee-keepers to crack." Now, as I have kept bees in skeps for something like twenty years, and have discarded skeps in favour of frame hives for the last four or five years, I would like to ask him by what magic he will insure the skeps swarming and the swarm giving a maiden swarm after giving a "crop" of surplus honey before the stock in a frame hive is ready to swarm. If the stock in the frame hive is properly managed it will be quite ready for swarming by the middle of May, and in all probability the stock in the skep will not swarm before the 7th of the same month at the very earliest, and not more than one or two out of a dozen stocks will give swarms during the first half of May at all. "A Hallamshire Bee-keeper" also says that to get the most profit by bee-keeping "stocks must be kept and wintered in skeps and the swarms put in frame hives." What, may I ask, is to be gained by this except a lot of trouble and loss of time? as bees will winter at least as well in a frame hive as in any skep, or, if you like, Stewarton hive that has ever been made. It seems to me "A Hallamshire Bee-keeper" should learn to manage and winter bees in frame hives before attempting to instruct others; this is easily done without any such absurdities as ventilating floors, so strongly recommended by "A Lanarkshire Bee-keeper," whose first "hint" in last week's Journal I most cordially endorse—viz., "To ask all bee-keepers to take nothing for granted, but test and prove everything before putting anything into general execution."

I have often been surprised to find bar-framists have not replied to many of the articles which have of late appeared in the Journal, and beginners will, I fear, be likely to take many things for granted simply because they have not been contradicted. I would ask all such to bear in mind the above-mentioned "hint" whenever they feel inclined to try any of the ways of bee-keeping given in such variety. There is no question in my mind as to the superiority of the bar-frame hive over all others, either for comb, or extracted or run honey; either for quantity or quality the skep is simply nowhere, and the Stewarton cannot give the comb honey in a saleable form for this part of the country. Even 2 lb. sections do not sell so readily as 1 lb., and as to supers they are quite unsaleable except at a lower price than extracted honey. I do not consider "A Lanarkshire Bee-keeper" has in any way "shown the superiority of supers over sections," as he assumes. Will he kindly say on which half of the hive he had the sections and supers this season to test which was best? as I find the bees will often fill tier above tier of sections over the centre and front of the hive, and at the same time not work the back row of sections in any of the crates. My crates hold twenty-four sections each, and I have had three or four of these on a hive at once.

I think "A Lanarkshire Bee-keeper" was a little mixed when he wrote his article for the Journal of the 13th inst., I mean when he says, "For indeed if people are as fastidious as I am they will hesitate before purchasing the finger-marked comb in sections, which will have to be broken up and sold in small pieces." This is just where the 1 lb. sections, so strongly recommended in the "Bee Journal" and by most bar-framists, are so vastly superior to the large bars of the Stewarton and the supers "A Lanarkshire Bee-keeper" is continually recommending. Sections do not have to be broken up to be sold in small pieces, as they are small pieces ready sealed up when finished by the bees; and if hives will give

"126 lbs. of fully finished sections" what more can anyone want? I last year took 62 lbs. of sections and 85 lbs. of extracted honey from a hive managed in the exact way "A Lanarkshire Bee-keeper" says is so fatal—keeping the queen breeding late in the season by feeding, and feeding and spreading brood in spring. It is the facility a frame-hive gives for spreading brood which is one of its most valuable points; and if the hive is kept crowded with bees as recommended by Mr. Cowan, the author of the system, there is no risk of chilled brood, it is only when part of the advice is acted on that mischief occurs.—A CAMBRIDGESHIRE BEE-KEEPER.

USEFUL HINTS.

I CANNOT do better than refer your readers to the article by "Felix" in the number for August 6th, page 123. Bee-keepers following the advice given there will not regret it.

Enlarging Hives.—As this season has shown many bee-keepers the folly of having too small hives, and carrying supers close to the brood of the stock hive, being the immediate cause of brood in supers and discolouration of combs. All such hives should be enlarged. This can be done either by nadiring or supering. Had the frames been on, the compound principle, nadiring, would have been the better plan, but when not, supering should be resorted to. An intermediate super of sufficient dimensions should be put on, and have it filled before the honey season is on, when the supers proper should be put on. The intermediate super should have a bar less than the hive has, the two outside ones on each side to have the extra width. When the supers proper are put on, care should be taken that the outside combs of intermediate supers are not sealed; if they are, break the seals, as bees dislike to travel over sealed honey to enter supers.

Preparing for Winter.—All hives not at the Heather should be put into proper order for standing the winter without delay. Feed where required, cover, and contract the entrance. Make stands secure, and put the ground in front of hives so that water will not stand in pools. Where roofs are deficient in ventilation have the defect remedied, and when once a hive is arranged make no alteration of hive or site. If moving is necessary, take the hives some miles distant for a month, when they may be brought back and set on the new site.

At the Heather.—If fine weather continues bees will make great weights. Great attention should be paid that none lack super room, as well as being careful not to give too much. When many are crowded together strict watch should be kept as to robbing, and if the bloom is past remove the frame at once.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

F. & A. Dickson & Sons, Chester.—*Catalogue of Dutch Roots.*
E. Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Bulbs, 1885 (illustrated).*

James Veitch & Sons, King's Road, Chelsea.—*Catalogues of Hyacinths and other Bulbs (illustrated), Trees, and Shrubs, and Lists of Carnations, Picotees, and Strawberries.*

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway.—*Catalogue of Bulbs, Fruit Trees, Roses, &c. (illustrated).*

William Paul & Son, Waltham Cross.—*Bulb Catalogue, 1885.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (Pitcairnie Correspondent).—Your letter has been forwarded in accordance with your request.

Rose Garden (A Lady Gardener).—Arrange the beds in a series of oblongs scalloped at the ends alternately, with round beds of the same width, following the curved outline of the ground, allowing plenty of grass between them, and the garden will look very well.

Vines Unsatisfactory (A Subscriber).—There are far too many canes the house. They should be at least 3 feet 6 inches apart (better 4 feet

6 inches), and the spurs upon them on opposite sides 18 inches. This would give you stronger and better ripened wood and much finer fruit. The roots are in a very poor kind of border, but as the Vines show plenty of fruit the soil cannot be in a very wet sour condition. We hardly think Muscats the size of peas now will come to anything. Apply a dressing of quicklime in autumn at the rate of a bushel per rod (30½ square yards), and point it in with a fork. It will not answer to make holes in the front wall and a border inside, as the roots will not be induced to enter it, or very tardily. Train the rods more thinly, and you will soon see a marked improvement.

Heating a House for Cucumbers and Tomatoes (*Idem*).—You will need bottom heat for the Cucumbers, two rows of 4-inch pipes for each bed, presuming there will be one on each side of the house with a pathway up the centre, and two rows of 4-inch pipes will be needed for top heat. Bottom heat is not necessary for Tomatoes, and for top heat you will require two rows of piping along both sides of the house to afford the requisite heat in winter.

Training a Passiflora (*A. J. R., Brixton*).—We scarcely understand your letter. You ask the "best time for slipping, and whether it would harm them if trained up now." If you desire to propagate from your plant, young shoots cut into lengths of 6 inches, and inserted in pots or boxes of very sandy soil, kept moist and covered with a bellglass or squares of glass, and stood in a warm shaded place, will strike now. The ends of the cuttings should be severed close to a joint from which the leaves are removed, and be inserted firmly a little more than half their length in the soil. The plants may be trained now over the space they are desired to cover, but not crowding them closely together, as the more thinly they are disposed the harder the growths will become, and the better they will flower next year.

Propagating Dracaenas (*J. B. W.*).—If you will split some flower pots lengthways and place the two parts together around the stems close to the leaves, fill the pots with a free compost of loam, leaf mould, and sand, affix them firmly, and keep the soil moist, the pots will become filled with roots, and the tops can be cut off. If the stem is rather hard, rooting is facilitated by notching; but if not hard, and they should not be where the pots are placed, they root freely without being cut. Roots are also emitted into thick balls of moss tied firmly round the stems and kept constantly moist in a warm house.

Grapes Shanking (*A. H. G.*).—It is very difficult to account for the Grapes shanking. Overcropping can hardly be the cause in the case of the Alicante, which is lightly cropped. No doubt if the "thousands of surface roots" were allowed to become dry there would be a break in the supply of sap, and this might cause the failure, especially if followed by a deluge of water and a damp atmosphere. Perhaps you started the Vines early, and forced out the bunches before there was good root-extension for their support. The other Vines are too heavily cropped, and the sooner the fruit is cut the better, or the Vines will be so weakened as to be unable to perfect even a fairly good crop this year. Do you open the ventilators very early in the morning? There is something wrong in the management somewhere, and we have observed that when a person makes such a mistake as to overburden young Vines he is apt to commit other errors. If the border is inside the house is it moist throughout the mass? If wet on the surface and dry below the Vines will not flourish. We are very willing to help you, but only appear able to do so by suggesting possible mistakes, or directing your attention to matters that may possibly require your attentive consideration.

Carnations (*L. P. Bouchier*).—Pride of Penshurst is good, and the pods do not split; Belle Halliday is also good, and you may grow both. You will find a list of Carnations and Picotees for beds on page 83, the varieties being arranged as nearly as possible in the order of merit under the respective sections. Strong plants of seedling tree Carnations will stand the winter the same as the others, and flower when large enough in the open air, and continue flowering for a long period.

Seakale (*Knocklinn*).—When Seakale is flowering the stems should not be cut down to the ground. The proper method is to take off the heads before the flowers expand, leaving all the foliage on the stems, as the leaves secrete matter for the formation and support of crowns at the base of the stems. The flower heads when cooked in a young succulent state are excellent, many persons considering them delicious. If you have any not too far advanced try them; ours were pinched off several weeks ago.

Blush Hyacinth (*A. M.*).—Your question is not as you suggest, "unreasonable," but quite the contrary. The Hyacinth to which you refer is not likely to be *La Grandesse*, the bulbs of which are too costly to be largely grown for "flower shops." It has a massive spike with closely set pure white bells, and is perhaps the finest white Hyacinth in cultivation. From your description of the flowers we suspect the variety to which you refer is either *Norma* or *Tubiflora*. The former is dwarf, with large bells thinly arranged on the spike, colour very delicate pink, changing almost to blush. The latter is flesh colour, with large bells and a taller spike. *Norma* we know is largely grown for market, and this is possibly the variety you have admired. You might order bulbs of both, which are cheap, but we should have the greater number of the variety last mentioned. We know a gentleman who has 700 plants grown of *Norma* for the decoration of his London mansion.

Heating Glass Structure (*Chas. E. Smith*).—We presume you wish the structure heated so as to afford two different temperatures, as you have a division in the house, practically forming two houses or divisions. In that case you will need four rows of 4-inch pipes in one structure to maintain a temperature of 60° to 65° at night, and 70° to 75° by day, as required for stove plants, and two rows in the other to afford a temperature suitable for greenhouse plants. It will be advisable to have the pipes so arranged that you can heat the houses separately or together, which will entail somewhat more expense in the first instance in valves as well as piping, but it will be more satisfactory and cheaper in the end. We should think the vertical boiler would be sufficiently powerful to heat the quantity of piping you will require, as you will not have 200 feet altogether, but its power will of course depend on its size, of which you do not furnish particulars. We should not go to the expense of another boiler until we had ascertained the heating capacity of the present one, which we think will be sufficiently powerful unless of a very small size. We should have 4-inch pipes, those being the best for general purposes.

Crassula coccinea (*Miss Kemp*).—We presume this is the plant to which you refer, and is commonly known as *Kalosanthes*. If all the shoots are cut down the plant will not flower next year, but will be fine the year after, and on this account cultivators often have two sets of plants; but it often happens that plants with only two shoots will produce but one head of bloom, and then the second shoot will be sure to follow the year after, and thus a plant may be made to flower every year. If this plant with two shoots offers to flower on both instead of one, and you wish the plant to flower every year, you must forego the pleasure of having both shoots to flower the first season. In that case, as soon as you can perceive the flower-buds in the spring, you must cut down one of the two shoots, and let the other one flower. The lower down the shoot is cut the better. If there is only an inch or two of it left, it is sure to produce three times the number of young shoots that will be necessary to retain. If you select three of the best placed, these will be enough for a plant so young; therefore, instead of two flower-heads, we have only one of them, and three others coming up to flower next season. As soon as the single truss of flowers begins to fade, about the middle of August, this flowering shoot must be cut down close likewise, and from it succession shoots will be obtained, so that in a large old specimen there are many flowering shoots and succession ones growing on at the same time; and, as soon as the plants are done flowering, the shoots which have borne the flowers are cut back to different lengths, according to the size or shape the plant is intended to be grown. Every portion of the old shoots cut off in August will make cuttings; but the best cuttings are obtained from the top ends of young vigorous shoots; they will root in a greenhouse, window, or frame. Abundance of air, strong sunlight, and plenty of water during their two months of active growth, but little during the rest of the summer and autumn, and scarcely any in winter, are the leading principles in their culture.

Names of Fruits (*E. H. B.*).—1, Nectarine Peach; 2, if the flowers are large it is Barrington; 3, too much decayed—perhaps a small specimen of Dr. Hogg; 1, Nectarine Victoria; 2, Rivers' Orange; 3, Albert Victor, but we cannot be certain about any of these, not knowing the size of the flowers. (*W. M. Rose*).—Citron des Carmes.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Mrs. H. S.*).—The specimens with no numbers attached are *Salisburia adiantifolia*, *Taxodium distichum*, *Antennaria plantaginifolia*. (*J. C.*).—1, *Sedum album*; 2, a *Selaginella* resembling a variety known in gardens as *densa*; 3, *Epilobium angustifolium*; 4, *Lycium europæum*; 5, *Campanula pumila*; 6, *Sedum spurium*. (*G. J.*).—1, *Lysimachia lanceolata*; 2, *Veronica longifolia*; 3, *V. gentianoides*; 4, *Spiræa salicifolia*; 5, insufficient to be recognised; 6, *Linaria cymbalaria*. (*J. D. P.*).—The plant with white flowers and pinnate leaves is *Spiræa Lindleyana*; the other is *Eucomis punctata*.

COVENT GARDEN MARKET.—AUGUST 26TH.

TRADE quiet, but at low prices clearances are eventually made.

THE CLERGYMAN'S FARM.

(Continued from page 172.)

A DESIRE to know our best sorts of Grass and Clover intimatedly prompted the sowing of small trial plots with the best selection to be had of them, and it was the remarkable result

of this experiment that fully convinced us of the value and importance of what is now termed alternate husbandry. On well-drained soil in a high state of fertility, free from all noxious weeds, ploughed deeply and worked to a fine tilth, sow a mixture of strong-growing Grass and Clover seed, and you will obtain a crop of highly nutritious fodder of twice the bulk of an ordinary crop of meadow hay for one, two, three, or even more consecutive years, provided the fertility is fully sustained by seasonable applications of manure. Turned to full account partly for hay and in part as green food, such a crop is not only profitable in itself, but it enables us to dispense with some portion both of manual and horse labour, and thus it adds to the profits and lessens the expenses of the farm. Economy of labour is a matter of vital importance to every farmer, and as a means to that end alternate husbandry merits general attention. Upon the clergyman's farm it should be applied to all the land not wanted for corn, roots, permanent pasture, or other green crops. Perennial Rye Grass, Trefoil, red and white Clover, is frequently the mixture for one or two years; and to impart a more permanent character to the herbage we add Cocksfoot, Timothy, Meadow Foftail, Alsike Clover, and Cow Grass. Whether we retain the crop for two or more years altogether depends upon the manner in which we are able to treat it. A heavy annual dressing of manure is necessary for the Grasses, and if we can add a liberal quantity of wood ashes to it the Clovers will derive much benefit from them.

It has been stated that by laying down the land in this manner we practically give it a rest, and it is subsequently broken up again in an improved fresh condition. This statement is erroneous and misleading, for the land requires no rest: it is simply a medium for giving food to plants, and so long as we keep it fully stored with fertility, taking especial care to restore to it the elements of plant life or food taken from it during each season of growth, we may continue cropping it with corn, roots, or green crops, with a feeling of certainty that there will be no falling-off in the quantity or quality of produce. Of equal importance to sustained fertility is mechanical division and drainage of the soil. The three things are to be regarded as indispensable. With them in judicious combination we can afford to laugh at the idea of the land wanting rest. Without them we are quite certain to have failure in some degree—not in a fitful uncertain manner, but strictly in proportion to our faulty culture or negligence of the soil. Far, however, from laughing at the grave assertion that the soil requires rest just as though it had sinews and muscles, we would express our regret that it has been made and repeated so frequently, for is not the long fallow a result of such teaching? Glibly enough are we told that the land wants rest when we ask why we still meet with bare fallows in summer, but in vain do we inquire why it wants rest. No doubt after two or three consecutive wet summers it is liable to become foul with perennial weeds, and more time and finer weather is required to eradicate them than can be had in spring.

To spend our lives in the culture of land, and not to understand clearly its nature and requirements, is really to court failure. Why do we drain soil? Why do we impart mechanical division to it? What is mechanical division? What sort of manure is best for each crop? When ought we to apply it? If farmyard manure or artificial manure best? What advantage or disadvantage is there in the use of either manure? These are some of the questions of vital importance to which we have striven to give plain answers repeatedly, and although they cannot be dealt with at length in these articles they cannot be altogether ignored, and may be answered briefly. We drain soil to relieve it from an accumulation of surface water, to prevent water rising from the subsoil to the surface by capillary attraction, and to check excessive evaporation, by which the air upon the surface is rendered moist and cold to the serious harm of tender vegetation. Mechanical division is imparted to the soil by an admixture of hard gritty matter, and its effect is to prevent

the soil from settling down into a hard, crude, inert mass, and in combination with drainage to afford free admission to the air and its fertilising gases. Speaking generally, genuine artificial manures are best if applied soon enough for each crop to derive full benefit from them during its growth. The advantage of artificial over farmyard manure is obvious, for by its use we avoid the heavy outlay involved in the manufacture, carting, and spreading of farmyard manure, only we must avoid all dealers' specialties for farms, procuring the manures separately from a reliable source and mixing them ourselves. We are fully aware that the doing this demands scientific knowledge of a higher nature than that possessed by an ordinary farmer, but if he be teachable there are plenty of means available for the acquisition of such knowledge; and the man who takes full advantage of the opportunity to learn and apply to practice the teaching of science will with care succeed when others fail, simply because he knows how to combine science with practice.

(To be continued.)

WORK ON THE HOME FARM.

Corn harvest is now in full progress. It was our intention to have threshed most of the Peas as they were carted from the field, but owing to unsettled weather we were unable to do so, and they were either stacked or put into barns. Wheat and Beans came next, the Beans being taken in the earlier part of the day, and the Wheat when the sun was high—say by 10 A.M. Much Wheat is already in the stack, for it ripened fast under the hot sun. Oats were left till the straw was well ripened, as we are always afraid of much heating in the stack, and subsequent mustiness. Barley, though last, is on the whole an excellent crop, but its culture has been extended so considerably that prices are almost certain to be low for some time to come. As soon as horses and men can be spared, harrows will be run over the stubbles to clear off most of the straw, then horse hoes and harrows will be brought into full play to render the land clean as soon as possible. Pigs will first be run over the stubbles to pick up loose and fallen corn. Draining of all wet land will promptly be taken in hand as men can be spared, for it is a good rule to do a certain number of acres every year, and so to spread out the expense that it may not at any time prove to be a serious matter. There must be careful supervision of this work, the pipes in each drain being put in along the entire length of it before any soil is put in, so that an inspection may be made and any faulty work set right, a single pipe put in out of line or too high or low, often spoiling a drain. See that the gradient is sufficiently correct from end to end, and the outfalls clear and well away from all risk of subsequent obstruction. Let corn ricks be thatched as soon as they are built, and see that an air of neatness and finish is imparted to the whole of them. Stubble Turnips may be sown as soon as the land is cleared and ploughed for them. Late-sown Turnips have not come well owing to the drought; late Mustard, too, is a comparative failure. We must, however, let no chance slip of sowing again so long as there remains any hope of getting even half a crop, for the value of any green crop later on in the season is so great that we must do our best to obtain it. Should the drought continue, we shall probably make exceptionally large sowings of Rye, Trifolium, and Winter Oats this autumn, all of them being valuable green crops, to which we shall duly turn next spring when pastures may be bare and winter stores run low.

REMARKS.

- 16th.—Fine, bright, and warm.
 17th.—Fine morning, rather cloudy in afternoon.
 18th.—Overcast morning, then brighter, but no sunshine.
 19th.—Dull and cold.
 20th.—Dull and cold, with a little drizzle at 11 A.M., then some sunshine. Thunder, rain and hail about 2 P.M., then showery.
 21st.—Fine morning, cloudy afternoon and evening, rain in night.
 22nd.—Generally cloudy till evening, then fine.
 Rainfall still very small, and temperature very near the average—slightly below it—
 G. J. SYMONS.

THE ROSE SEASON OF 1885.

AS the din of battle has now ceased and the weapons of war laid aside for another year, for the combatants in this strife are like those Italian commanders, of whom we read that after a hard summer's fighting they used to go into winter quarters, so as to prolong the strife, their trade being likely to suffer if the contests were too quickly decided. It may now be a good time to do as I have been wont to do in former years—take a survey of the past season. I feel, however, some difficulty, for I have seen the most conflicting accounts, and on matters which one would think there could be little room for difference of opinion. Let me take one example. It was stated in one gardening paper that the blooms at South Kensington stood remarkably well, as there was a cool breeze through the conservatory—very different from the day before; while another writer stated that the blooms opened more rapidly than he ever recollected. No less an authority than Canon Hole has stated that it was the best season he remembered for forty years, while I have seen the statement of others that it was inferior to last year.

I must, then, take my own lines, and not be influenced by any of the opinions that I have read or heard. I have had, again, a tolerably fair opportunity of judging; for although I have gone neither to Wales or Scotland, I have enjoyed the opportunity of judging at thirteen or fourteen shows, beginning at Canterbury on June 26th, and ending at Darlington on July 25th, and have moreover visited many private and public gardens where the Rose reigns supreme. But the difficulty of judging about the quality of the Rose season has been considerably increased of late years. In the first place the Rose season, or rather the Rose-showing season, is very different from what it used to be. Before the establishment of the National Rose Society Rose shows were few and the exhibition season was soon over; in fact, after the first week in July, although Roses might be seen at other shows, they held only a secondary place. When considering the character of the Rose season only these had to be taken into account; but now all this is changed. As I have said, from the end of June up to the very end of July exhibitions in which the Rose forms not the principal but the sole feature are held. The number of exhibitors has multiplied beyond what one would have at one time deemed possible, and as most growers are influenced by the condition of their own plants in giving their opinion concerning the general growth, it comes to pass that we have so many different opinions; and one has, in deciding as to the character of the Rose season, not to think over some three or four shows, but over some three or four and twenty and a corresponding number of gardens. Another reason why it is difficult to judge is that the requirements of the Rose-grower and exhibitor, and I may add the demands of the public, have so much advanced of late years. The standard of excellence is so much higher than it used to be; the size to which Roses have attained without destroying their symmetry

is so remarkable, that we must, however difficult it may be, dismiss from our memory the seasons that have past, and only judge by the present high standard. I am no *temporis laudator acti*. I believe that stands of Roses which fifteen years ago excited applause and wonder would look miserable alongside of winning stands of the present day; and hence it is most difficult now, so used have exhibitors and the public become to the very finest exhibits, that it is very difficult to bring forward anything which shall come out prominently above all others. There is a more level style of exhibiting, but the level is higher.

It will thus be seen that I am fully alive to the difficulties which beset the task which I have before me, and that my opinion is one not hastily given. That opinion is most decidedly that it has been a good Rose season—the best, in fact, that we have had for some years, but briefer than usual owing to the very dry weather, which, although unfavourable to the exhibitor, was on the other hand favourable to the managers of Rose shows. I have attended my usual number, have heard about a good many others, and with the exception of some rain at Wirral I am not aware of one where fine weather did not encourage the secretaries and committees of shows. I do not recollect any season in which there was so total an absence of aphides, or when the Rose maggot was less troublesome. I fancy I see some holding up their hands in wonder at such a barefaced statement, notably my good friend Mr. Williams of Alderminster, who seems to have been specially favoured by them, but none the less do I maintain this opinion. In my own garden from beginning to end, on the walls or in the open, I hardly saw one. I have visited many gardens and have conversed with many growers, and that what I saw and heard fully confirmed this opinion. One would have thought the long-continued dry weather would have been favourable to their development, but some cause or other seems to have militated against them, and indeed with us all insect plagues have to a great extent been absent. The dry weather, too, was up to the middle of July favourable for the light Roses. Such flowers as Captain Christy, Madame Lacharme, and Mons. Noman had a good time of it and were shown in admirable condition, but in some places and soils it was too hot for the higher-coloured flowers; but it is a curious illustration of the uncertainty that clings to Rose-growing, that while last year a good bloom of Marie Baumann was rarely seen and Alfred Colomb was everywhere good, the case has been reversed this year. Marie Baumann has been shown generally, and Alfred Colomb rarely, well. Why this should be so in Roses so nearly alike it is very hard to say; indeed this peculiarity of one Rose coming out prominently in some particular season is one of those problems no “fellar can understand.” I do not know that this year any one variety has thus stood out prominently; indeed in the earlier part of the season there was often much difficulty in saying what Rose should claim the merit of being best in the show, but it is very difficult to find flowers that will beat A. K. Williams or Marie Baumann.

There has been no diminution either in the number of Rose shows or in the vigour with which they have been carried out. The National Rose Society has again had a most successful season, their shows at South Kensington and at Manchester having been very successful—that at South Kensington, both in the extent of the exhibition and the quality of the flowers, have been, in my opinion, superior to any of its predecessors. But here again the extreme hot weather of the early days of July told much against the smaller exhibitors, and the “fallings out” were much larger than usual, and had all who entered been able to come to the starting post I think it would have taxed even Mr. Barron's skilled hand to have given them a fair start. At Manchester the same held good. Many well-known exhibitors were absent, owing simply to the fact that the heat had driven their flowers out of bloom. But as showing how uncertain a thing Rose-showing is, Mr. Whitwell of Darlington, who has always

shown so well there, was not in bloom; and, indeed, when I was in his garden previous to the Darlington Show on July 25th, his Roses were not nearly in full bloom. How trying the weather then was may be evidenced in the fact that Messrs. Paul & Son, B. R. Cant, Prince, the Rev. J. W. Pemberton, and other distinguished growers, were not able to put in an appearance, and as telegram after telegram arrived announcing their failure the courage of a less experienced manager than Mr. Whitwell might have "oozed out at his fingers' ends." But he was not disheartened, and the northern men boldly sustained the reputation of the Show. The earlier shows, on the other hand, exhibited a decided advance—Canterbury, Reigate, Farningham, and Sutton all showing a large increase. One other very satisfactory fact has to be recorded—viz., that the number of inferior blooms exhibited at all the shows and slovenly ways of setting up have greatly diminished. The competition becomes more severe, and growers are put upon their mettle. The National Rose Society may well be proud of the impetus it has given to Rose-growing. Nor has it confined itself to the exhibition flowers only; garden Roses have been encouraged, and many a long-forgotten favourite has been inquired after. Questions of varied character are brought before it, and its decision is regarded as final in all matters connected with the Rose. One or two questions will have to be brought before it when the Committee meets again.

I do not think that there has been any such startling results of exhibiting as I was enabled to chronicle last year. Mr. Pemberton secured the challenge trophy, and exhibited, as he always does, well; but the weather was too much for even him, and he could not continue from the beginning to the end of the season, as he did in 1884. Mr. Slaughter again resumed the position he occupied in 1883, and exhibited in fine style. Mr. Girdlestone is evidently coming to the front, and is showing what can be done even in the Bagshot sand by an enthusiastic grower. In the north the Messrs. Harkness have developed into first-rate exhibitors, and their exhibits at Darlington and Newcastle were of a very superior order. It is pleasing to record the uprising of new exhibitors, for older ones drop off, and we want to have their places supplied.

Again have Tea Roses been shown in increasing numbers and in great beauty; and here let me say how heartily welcome was the sight of Mr. George Prince, after his long and most severe illness, at the South Kensington Show; still, indeed, showing signs of its severity, but giving us hope that he will one day resume his old place amongst us. The impetus given to Tea Rose-growing has been in great measure due to him, and he must rejoice to think how many apt pupils he has had. On this occasion we cannot pass by the remarkable success of Mr. E. Claxton of Liverpool, who, with a small number of trees, has been enabled to achieve a great success. One Rose which he has specially patronised, *Madame Cusin*, has a great future before it, owing mainly to the excellent manner in which he has shown it.

With regard to new Roses, there is very little to record. Mr. Henry Bennett has succeeded in raising a new Rose—Mrs. John Laing, which, if I mistake not, will be a much greater favourite than *Her Majesty*, and he is evidently reaping the results now of his careful hybridising. That wonderfully puffed Rose, *Gloire Lyonnaise*, which was described as a yellow *Perpetual*, has proved an egregious take-in. It is a pretty Rose of the *Capitaine Christy* type, but yellow? Well, you may perhaps discover at the base of the petals the very slightest tinge of sulphur yellow. It may be, as was said to me by a thoroughly good rosarian, that it is the forerunner of a new race, and that that is its claim to merit. Perhaps so; but the same was said of *La France*, of the same raiser, but nothing came of it. It remains, indeed, one of the grandest Roses for the exhibitor and the garden that we have, but it has produced no progeny. *Merveille de Lyon* has proved, I fear, a disappointing Rose. Nothing can exceed its purity when caught in perfection; but, alas, that it is too seldom! In every

stand that I have seen of it this year there was always a large number which showed the eye. A new Tea Rose, *Madame de Watteville*, is likely to become a general favourite. It is white, slightly shaded and edged with salmon, and is very attractive. The Hon. Edith Gifford has fully established its claim to be one of the very best of its class. *Ulrich Brunner*, though not a new Rose, has come out marvellously this year; and, indeed, if any Rose may claim to give a title to the year, one may say it was an *Ulrich Brunner* year. I have not seen Messrs. Paul & Son's *Madame Norman Neruda*, so can say nothing about it, but I hear a very high character of it. It will thus be seen that our catalogues are not likely to be much burdened by new Roses. There may still be some unknown to fame, but they have as yet bloomed in the desert.

I cannot conclude this rapid survey of the year without a word of thanks to all with whom I have been associated during the past season. I have received unvarying kindness, and have been further strengthened in the conclusion I came to long ago—that Rose-growers are a "good set of fellows," and to me it has been a cause of much thankfulness that I have been enabled to fulfil every engagement that I made, and when one is verging on to being a septuagenarian can I be thankful enough?—D., *Deal*.

NOTES ON FRUIT AND FRUIT TREES.

THE lovely tintings of purple, crimson, and gold now beginning to attract the eye on the ripening and clustering fruits of Apple, Pear, and Plum, forcibly remind us of the rapidly declining days of a charming summer. Although the abundant blossom which clothed the trees in early spring augured well for a good general crop of fruit in 1885, our expectations were not fully realised, but we have not much reason to be dissatisfied. It is true the Apple crop is not quite so bountiful as it was a couple of years ago, and this was no doubt owing to the late spring frosts, which occurred when the latter were in full blossom. In some districts, however, notably the southern and western counties, the crop is above the average, there being only a few isolated instances of failure known. Many of the orchards in the western counties had their trees badly infested with blight, and this, coupled with the excessive drought, has caused a great quantity of the fruit to fall prematurely, and will, no doubt, prevent the remainder of the crop from attaining its normal size. In some of the districts in Kent where fruit-growing is extensively carried on, we recently saw, in the course of a drive, the majority of the Apple trees bending under the weight of its crop.

Our American cousins are looking forward to having a bountiful harvest, and round the environs of Homburg in Germany we are told there is the heaviest crop that has been borne for years. Most of the Apple trees about Homburg are planted in the hedgerows by the roadside. It is a great pity that this plan is so seldom adopted in England, where so many hundreds of miles of favourable sites exist by the sides of our main roads. The planting of railway embankments with fruit trees has been suggested times out of number, but, before we attempt this, let our hedgerows by the roadsides be made both attractive, useful, and a source of profit. The total acreage devoted to Apple culture in Great Britain, however bountiful the crop, cannot supply the demand, hence the many thousands of barrels which are imported annually into this country. Now were Apple trees planted as we suggest, the farmer would possess a fruitful source of income, as well as the consumer the better qualities of home-grown fruit at a cheaper rate. Farmers are, however, beginning to find that fruit-growing is a profitable business as regards bush fruits and Strawberries, and the day is not far distant when they will become alive to the importance of planting Apple trees in the hedgerows.

Of Pears there is a grand crop all through the country, but the fruit will, in consequence of the drought, be far below the average in size. It will, however, be better ripened and well coloured. These remarks refer principally to standards and pyramids, but in the case of cordon-trained trees well looked after in watering and so on, the fruit will be very fine. We are more impressed than ever with the value of cordon-trained trees for walls; the trees are more certain of a crop, and the quality of the fruit superior to those grown in any other form. Out of a collection of some hundreds of cordons we have to record one failure this season, and that is in respect of *Pitmaston Duchess*, which has not borne a single fruit. It is planted near the

Duchesse d'Angoulême in the same soil and situation, and the latter is bearing a fine crop. It is somewhat curious how erratic the former is in regard to fruiting in certain districts. Mr. Luckhurst, we believe, found it very difficult to manage at Oldlands, and yet all other varieties succeeded admirably there. It was at the latter's wish that we tried it, but after three years' experience we are not very favourably impressed with it. It is undoubtedly a grand Pear where it can be grown successfully. A friend from Liverpool told us the other day that it succeeds well in that neighbourhood. A northern latitude may perhaps be more favourable to it than down south. Durondeau, Brockworth Park, Beurré Bachelier, Gansel's Bergamot, Thompson's, Emile d'Heyst, Olivier des Serres, Madame Millet, are a few of the heavily cropped cordons. When we write heavily cropped, we do not mean that the trees are overcropped, as every tree, according to its variety, had its fruit thinned in its infantine stage. A new Pear, Directeur Alphand, sent out by Messrs. Veitch a year or so ago, is fruiting, but the tree is not a vigorous grower.

Our pyramids are all carrying grand crops. These trees are fine well-trained examples, but had for years very meagre crops of fruit. In the spring time the trees would be a mass of blossom, but no fruit would set, in spite of an elaborate system of protecting the blossom from frost by means of a framework of wood and tiffany. The trees were a perfect thicket of wood and fruit buds, the latter far too numerous in fact. A careful thinning out of the branches was done the first year; the second, thinning out the fruit spurs, with judicious disbudding in summer and root-pruning in autumn; and the third and present season good crops of fruit. Although we rubbed off a vast number of the fruit buds while dormant, yet so numerous were they when in blossom that we decided to still further reduce their number. As the greater part of our pyramid Pears are planted two of a sort, we thought it would be interesting to try the effect of thinning the blossoms, and the young fruit afterwards on one of a sort only, leaving the others to Nature. The crop is decidedly more even, and the fruit in greater size and quantity where the thinning had been practised than on the unthinned trees.

It was a tedious task to thin out so many Pears in such a small state, but we are convinced that it more than paid for our trouble. We give great attention to the thinning of our Grapes and Peaches, and why not of the choice Pears, Apples, Plums, and Cherries? The thinning requires a certain amount of judgment, and must be performed as soon as the young fruit has set, and it can be seen which of the young is likely to take the lead, and not when the fruit has attained the size of a walnut. By this means an even and handsome crop of fruit can be secured, whilst if left unthinned the chances are, that although there might have been the early promise of a good crop, fully three-fourths would, in a dry season like the present, have dropped prematurely, or have been considerably under the average in size. An espalier-trained tree of Winter Nelis set a heavy crop. We thinned the fruit on one-half of the tree and left the other untouched. The thinned fruits are much larger and better shaped, as well as in greater quantity, whilst the other half has lost two thirds of its crop.

Such is the result of our experience of the timely thinning of the young fruit, and although it would not be practicable in the case of large trees, yet in the case of pyramids, espalier, and wall-trained trees, we are fully convinced that this simple operation, judiciously performed, will effect more good towards keeping trees in a healthy bearing condition than any amount of the severe winter pruning to which trees are often subjected.

Sufficient importance is not always attached to the value of summer pruning. We do not mean the pernicious system of allowing pyramid and espalier-trained trees to develop a large quantity of growth, and then suddenly remove it in a wholesale manner in July and August, but the timely and judicious disbudding extended over nearly the whole period of growth. Trees that are subjected to the first-named process are the reverse of fruitful. We have seen trees a perfect thicket of wood, the "spurs" left at the time of the wholesale pruning being only capable of producing a crop of gross and useless shoots the next year. Too often the situation, the soil, or the variety is condemned, when the real cause is too apparent in the mismanagement of the trees. The intelligent gardener has long been aware of these facts, and carries them out in practice, but there are still numbers who fail to see, or neglect to make use of, the benefits of timely and judicious disbudding.

Of Plums and Damsons there is a heavy crop throughout the country. Damsons are a very uncertain crop in some localities. The finest crops we have ever seen are growing on trees on the limestone formation in Worcestershire, and this year after year. This fact induces us to come to the conclusion that the presence

of lime in the soil is an important factor in the successful culture of Damsons. Farmers and cottagers in the west of England find the latter a paying crop, as in addition to supplying the various markets in the kingdom, a vast quantity is purchased for dyeing purposes. We are not quite so sure whether the orthodox plan of nailing in closely the shoots of the Plums in summer and winter is a sound practice. On a west wall we have two very old trees of Green Gage and Victoria Plums, which owing to many years of neglect had ceased to bear, and indeed appeared to all purposes only fit for "grubbing" up and consigning to the fire heap and replacing with young trees. These were allowed to make what growth they could last summer, which was not very extensive, without disbudding, &c. We were too busy with other matters in the autumn to "grub" them up, and the time went on until March, when on examining the shoots which were protruding from the main branches, we found them well furnished with fruit buds. These in due time developed into flower, and finally into fruit. The foliage sheltered the young fruit, and now the old trees have a marvellous crop from the tip to the base of the shoots. The non-nailing of the shoots in summer and winter had evidently given them a better chance of becoming more thoroughly ripened than if they had been nailed in and crowded with foliage. We shall therefore give our old friends another chance, and see what can be done next season. The Peach crop out of doors has not been so good this season, although the wood had such an excellent chance last year of getting well ripened. Just at the time they were in flower cold easterly winds prevailed, with a few sharp frosts, and this in our own neighbourhood was the primary cause of the failure. The trees are promising well for next year.

Apricots have been a fair crop, but many trees have suffered from that mysterious phenomena, the sudden dying of the branches. In our own case a fine young tree of Moor Park lost two-thirds of its branches. Cherries have borne abundantly. Büttner's Black Heart, Bigarreau Napoleon, and May Duke, cordon-trained, have borne fine fruits. Last spring we planted a new north wall upwards of a hundred yards long with some splendid maiden cordons of Archduke, Governor Wood, Florence Bigarreau, and the old Bigarreau, Black Tartarian, and other Cherries, which are making fine trees. On the same wall are growing similarly fine cordon Kirke's, Jefferson, Coe's Golden Drop, McLaughlin's Gage, and Angelina Burdett Plums. Many will, perhaps, be of opinion that these varieties will not succeed on a north aspect. Of course we do not expect an early crop, but we have good hopes of having good fruit of the excellent varieties above referred to coming in for use when those on warmer aspects are gone. At any rate we are giving the plan a good trial.

Bush fruit has been very good indeed. Gooseberry trees have not as yet suffered from the depredations of the caterpillar of the Gooseberry moth. Our latest fruit to gather was the sweet Champagne class of Gooseberries. A good variety of very much the same type is the Ironmonger—sweet and dark-skinned. Raby Castle and the old White Dutch Currants are still supplying us with fine fruit from a low north wall. Raspberries were very abundant for a time, but the continued drought checked the supply some time since. Out of several varieties we have found Carter's Prolific the best. We make it a point to cut away the old fruiting canes as soon as they have ceased to bear, to give the young canes the benefit of the light.

Strawberries have been very fine—the Vicomtesse Hericart de Thury being our earliest, and Bicton Pine and Loxford Hall our latest crops. The Hautbois have fruited better this year, the variety known as the Royal being the most prolific. Of the red and white Alpines we have had an incessant supply since the beginning of June. We have the runnerless type, the red and white Gallions of the Belgians, and Quatre Saisons, a large red type of Alpines, but these do not supersede the old forms from which we hope to gather daily until November. These we grow between the fruit trees and on sloping banks where little else would grow. Finally, a word as to the value of glass copings for protecting fruit trees in spring. We have tried it for three seasons, and find it of the utmost value both as a protector and in hastening the ripening of fruit of Pears, Apricots, Plums, and Cherries, and very considerably improving their flavour. A simple and inexpensive glass coping, with moveable panes of glass, will soon pay for itself by the protection it affords to the fruit trees when in blossom, and the greater certainty of a crop in adverse weather.—A KENTISH GARDENER.

VERBENA CULTURE.

As this is one of the most beautiful of all bedding plants, and perhaps one of the oldest, a few hints on its culture may possibly be of service to

the inexperienced. Cuttings should have been inserted a fortnight ago for those who require a large number of plants for bedding; but still, if a slight hothed is at hand with a temperature of 60° they will strike readily. Choose shoots that spring from the base of the plants. The best plan to make sure of some good autumn cuttings is to pot a few of the surplus plants after the hedding-out is finished into 48-size pots, keeping them pinched to within three weeks of the time that cuttings are required, then placing them in a cool frame and keeping it rather close, so that the shoots will be tender. Three cuttings may be inserted in a small 60-pot, using a compost of equal proportions of loam and leaf mould with a free admixture of sand. Care should be taken not to let the cuttings wither before they are inserted, or they may fail to strike. They should not be exposed to the sun till they are well rooted. Those who have not the convenience to strike them in heat may succeed with a cool frame kept quite close for a few days, frequently sprinkling the cuttings.

As soon as the plants are ready for potting they should be placed in 32-size pots without parting any of them, using a compost of three parts good loam and one part decayed hotbed manure and leaf mould. They must then be placed in a frame facing the south, as well-ripened sturdy wood is the object, this giving a good supply of cuttings in the spring. If allowed to become dry the aphids and mildew will soon appear. A fumigating with tobacco paper will destroy the aphids, and a sprinkling of sulphur will destroy the mildew. On the approach of frost the plants should be removed into a cool house, keeping them close to the glass and free from decayed leaves, as they are liable to damp off. About the middle of January they may be placed on a shelf in an intermediate house. When cuttings are ready they can be inserted in pots or shallow pans of sandy soil. They will strike readily in a hothed with top heat ranging between 60° and 70°.

No time should be lost in propagating as the cuttings advance, for if they become hard they take six or seven days longer to strike. When the plants are shifted they should be placed in the shade for a week, for if the sun shines on the pots it will scorch the roots and some of the plants will die.

At the commencement of April the propagating should be finished for the production of good plants. When these are properly hardened they may be planted 4 inches apart in good soil 1 foot deep, and pressed firmly in frames facing south, keeping the frames close for about ten days, shading the plants when required until established, never allowing the soil to become dry, and pinching the shoots occasionally.

I can recommend the following varieties as good bedders:—Purple King, Defiance, Mrs. Fisher, Boule de Neige, Pre-eminent, Lustrous, Mrs. Leach, Surpasse Auricula, Zulu, August Renz, Lovely Blue, Eclipse, Kate Stevens, Miss Edwards, Favourite, Géant des Batailles, Madame Anna, Hampton Court Crimson, F. Delaux, Mrs. Halford, Ariosto Improved, Lady Londesborough, Lady Cowley, Merry Maid, White Perfection, Madame H. S'enger, Flambeau, and Earl of Beaconsfield.—C. H. STEPHENS.

CULTIVATION OF THE PEA.

In giving a few remarks under this heading I do not intend to give a long list of the various sorts of Peas, but simply as to their cultivation in general as practised by myself. In some localities sticks or stakes can be obtained on the estate, at another every bundle must be purchased, and as I have had both of these to contend with, I will mention a few varieties to suit either. Where sticks are difficult to be obtained I would say, Grow American Wonder, Chelsea Gem, and Little Gem for the earliest crop. For the second I would mention Robert Fenn, about 2½ feet, and for a later crop Omega, 2½ feet. Everyone wishing to grow Peas would be able to get sticks to support these. Then, again, if I had plenty of sticks at command for the first crop I should sow Chelsea Gem and American Wonder, as 2 feet apart from row to row is sufficient for them, and the way I manage is to sow thickly in boxes in February, and place them in a vinery that is started at about that time, and when sufficiently advanced harden them, and eventually plant them on a well-prepared south border, and protect them with fern, or the lower branches of Beech trees to which the leaves still adhere. As these varieties can be grown so close together I think nothing is lost.

Then, again, if sticks were plentiful I should certainly sow the taller-growing sorts; then for the first, after one or both of those mentioned before, I would have William I, 3 feet; Laxton's Alpha, 4 feet; and Dr. Hogg, 4 feet. For second, Champion of England, 5 feet; Dr. Maclean, 3½ feet; Gladiator, 3 feet; and Telephone, which is 6 feet; and for the last crop I find nothing better than Ne Plus Ultra and Sturdy, their heights being 6 feet and 3 feet respectively. It is almost useless in this unsettled climate to sow the late varieties after the end of June—I mean as a rule—but it is possible that different localities might produce different results in this respect.

Many gardeners sow in November, but experience teaches me nothing is gained by so doing. As I before wrote, I prefer the system of sowing in heat and transplanting. For the third sowing I prepare trenches as for Celery, but not so deep, and put in manure in the same way, fork it well up, sow the seeds, and cover them with about 2 inches of the soil taken out of the

trench. It is a good plan before covering the seeds to give them a coating of soot and lime, as this prevents insects attacking the seeds. Another very good plan is to damp the seeds and dust them with red lead and another to sprinkle petroleum over them. The above remedies are to prevent underground attacks, but as soon as the seeds are above ground the sparrows attack them, and the only thing I have found effectual is to put Pea protectors or nets over them and again this is necessary when they begin to pod. If this is not attended to the birds will surely spoil the crop.—ROBERT D. LONG.

AMONGST THE NOVELTIES.

(Continued from page 190.)

PEAS.—Abundance (Bliss) I received from New York too late to test its earliness, but I can speak well as to its quality and prolific bearing. It is dwarf and very branching. Culverwell's Triumph I found good at all points, and I strongly recommend it. It grows from 2½ feet to 3 feet, bears abundantly handsome pods containing peas of very good quality. Victor is a remarkably sweet Pea—the sweetest I have tasted this season. The pods are not very large, but the peas are fine and packed so tightly that they are rather hard to shell. The foliage is very dark. Rural New Yorker is a very fair early Pea and bears well. Electric Light is a good Pea. Culverwell's Paragon I have again found invaluable. With many varieties I have found gaps in the pods, but I never find a single Pea wanting with Paragon, and no better Pea can be desired for any purpose. Even when they are old the peas boil sweet. Evolution is a very handsome-podded Pea, but unfortunately mine had the blight so bad that I could not judge it fairly. I hope to do better with it next year. Sturdy was completely destroyed by blight. Of Duke of Albany I sowed four rows about 4 yards long on the same day. I think very highly indeed of this Pea. It has an exceedingly handsome pod containing from nine to eleven fine peas of very good quality. It bears very abundantly and continues long in use. Although my four rows were grown on nothing but gravel enriched with plenty of muck, I managed to take a second at a show one week with it, a second at another show the next week, and a third the week after that. I could not have done it with any other Pea I grow, although I have about twenty varieties. Daniels' Early Longpod for market I do not care for. It is a great bearer, but grows too tall for field work and is not of good quality enough for the garden.

POTATOES.—Daniels' Norfolk Hero is a grand Potato. Fine tubers of splendid quality, being very white, floury, and of good flavour. To anyone who has a hot soil like mine I strongly recommend this Potato. It stands erect and grows strong when all other varieties but Clarke's Maincrop are looking weak and dwindly. Clarke's Maincrop is a very similar Potato, is very good, and is a capital variety for a hot gravelly soil. Beauty of Eydon is a very good Potato, but could not stand the drought well. I hope to try it more successfully next year with Purple and Gold, which also felt the drought.

General Gordon is a handsome variety. The Dean, I consider, an improvement on Vicar of Laleham, and am rather taken with it. It is a handsome and good Potato. These are the only new varieties I tried with the exception of one of my own, and it goes without saying that I consider my own chick better than any other. Of older varieties, I must say a word for Reading Russet, Matchless (or Holborn Favourite), and Snowdrop. They are three good Potatoes in every way, and whoever tries them will not be disappointed.

I may add that the White Plume Celery looks well, although I am rather behind with it. I should judge that it will be a great acquisition.

I have now given my experiences in testing the novelties, and hope a better man will continue the subject for our guidance next year.—H. S. EASTY.

SINGLETON ABBEY.

SINGLETON, the residence of Mrs. J. H. Vivian, is situated on a finely wooded eminence overlooking Swansea Bay towards the south, and is some two miles to the west of the town. The house, which is built in the Elizabethan style, is of moderate dimensions. It is closely surrounded with flower gardens, roseries, archery grounds, and noble trees and shrubs of luxuriant growth. To give an idea of the climate, it may be stated that Camellias planted outside grow to the size of large Portugal Laurels, and produce thousands of flowers in the spring and early summer months. The south side of the house is covered with a choice collection of climbers, amongst which are large plants of the white and yellow Banksian Roses attaining a height of 40 feet. These were clothed with hundreds of blooms at the time of my visit. Ceanothus puniceus and other plants were also flowering in great profusion. Attached to the house on the west side is a span-roofed conservatory with Tree Ferns planted out in the centre, and large Camellias and other plants in pots placed round the sides. The roof was draped with different varieties of climbers hanging down in long festoons.

Singleton is famed for its fine collection of arboreal and hybrid Rhododendrons, and for its fine specimens of rare Coniferæ and other trees and shrubs. There are few places in this country where one sees the tenderer varieties of Rhododendrons growing so freely as they do here, except perhaps in a few favoured localities in Cornwall. Though the climate is mild the soil in many places is poor, and much of the success attending the growth of the trees and shrubs is due to the care and attention of Mr. Harris, Mrs. Vivian's gardener, who has spared no trouble in draining the ground and improving the soil where the finer and more delicate kinds are planted. Towering up from amongst the Rhododendrons in the American ground are giant Oaks and Elms and large trees of *Araucaria Cunninghamii*, *Wellingtonia gigantea*, *Taxodium sempervirens*, *Cryptomeria japonica*, and many others from 80 to 90 feet high, affording shade and shelter to some of the finest varieties of Rhododendrons in cultivation. Many of these have attained a height of 30 feet, and have in themselves a true arboreal appearance. I was fortunate in seeing some of the best of them in flower at the time of my visit, and also in having Mr. Harris for a guide, who knows the history of almost every plant on the place, the date of planting, and when last shifted. He has raised many seedlings from the best species of the Himalayan section during the time he has been at Singleton, which in most cases keep true to character.

wide and 9 feet high, running east and west, with a division in the centre. Some of the trees in this house are planted near the centre of the inside border and have a clean stem of 4 feet before reaching the trellis. They are trained on both sides of the house, and it is surprising to see the difference there is in the time of the fruit ripening on the same tree when a portion is trained on the south side of the roof and the other on the north side. The portion trained on the south side ripens fully two weeks earlier than that on the north side. This system would be a great advantage to amateurs and others where the glass houses are limited in prolonging the succession from the same tree. The south side of the first division is planted with Hale's Early and Royal George, and the north side with Elruge Nectarine. The second division is planted with Early Louise and Bellegarde Peaches. Though some of the trees are old and not so good as those on the wall, the most of them were swelling off good crops in both divisions. In passing I might mention a vagary of a Royal George Peach tree in this house. One branch of it is conspicuous for its precocity. It is growing precisely under the same conditions as the rest of the tree, and yet the fruit on it ripens about two weeks earlier than any other portion of the tree. It was carrying three fine highly coloured fruits, which were nearly ripe when I saw it, while the remainder of the crop had scarcely done stoning. Mr. Harris has been observing the pre-

Fig. 35.—SINGLETON ABBEY.

Most of the Rhododendrons and many of the finer kinds of Coniferæ are labelled in large print, so that the visitor interested in either has no difficulty whatever in obtaining their names.

The kitchen garden and forcing and plant houses are situated at the north side of the park, and at a convenient distance from the house. The garden is enclosed with high walls, which are covered with well-trained trees. It would be difficult to find a better lot of Peach trees in the country than those at Singleton. The Peach wall forms part of a circle. It is 15 feet high and 90 yards long. The trees are planted at the distance of 20 feet apart, and the wall is regularly covered from top to bottom with healthy young trees in the best bearing condition possible. They bear heavy crops annually, which in ordinary seasons ripen well. There is a good collection of Peaches, comprising both early and late varieties. Amongst these are Walburton Admirable, Alexander, Salwey, Sea Eagle, Early Louise, Early Beatrice—the earliest of all—Hale's Early, and Dr. Hogg. The latter is a second early and a great favourite at Singleton. To show how well Peaches do here I may mention that a three-year-old tree of Sea Eagle produced no less than eighty-three fine fruits, a dish of which took the first prize at the Healthier Exhibition last year in a class where there was no fewer than thirty competitors. The Peach border was all made by Mr. Harris, and I do not hesitate to say that I never saw healthier or better trained trees anywhere, or trees carrying better crops throughout.

After leaving the Peach wall I was shown through the houses, which are mostly old and have not the same appliances as modern erections. Notwithstanding this Mr. Harris grows both fruit and plants successfully. The first we entered was a half-span Peach-house 80 feet long by 18 feet

cocity of this branch for the last few years and cannot account for it. He is, however, of opinion that its early quality is fixed, and he purposes propagating sufficient of it to plant one-half of the house.

The next house contained a good collection of greenhouse plants, amongst which were several sweet-scented Camellias, a quality rarely found in this plant. Mr. Harris is working up a stock of them, as they are highly esteemed by his employer, and no doubt when they become better known they will be general favourites. The collection of Indian Azaleas and Rhododendrons is made up of the best varieties. Azalea Fielder's White is the favourite for early forcing. It is had in flower from Christmas on till the other varieties come into bloom of their own accord. Pauline Mardener is the best coloured variety for forcing, and is very extensively grown along with Fielder's White. A plant of Rhododendron Edgworthii in this house produced no less than 100 trusses of its pure white cup-shaped flowers in April. A fine plant of *R. Sesterianum*, a companion to Edgworthii, flowers profusely. Part of the roof is covered with a large plant of *Maréchal Niel* Rose, which keeps up a supply of blooms for cutting, and it does not interfere much with the plants growing beneath.

The next house is filled with a healthy collection of Orchids, amongst which were some fine specimens of *Aerides odoratum*, *A. virens* Dayanum, and a particularly fine plant of *A. Fieldingii*, which had a spike more than 2 feet in length. A variety of *Vanda suavis* had six spikes and nine flowers on each, and a plant of *V. gigantea* bears three spikes annually on the main shoot, with from seventeen to eighteen flowers on each. There were also some fine plants of *Saccolabium præmorsum*, *S. guttatum*, and *S. Blumei* Dayi. Besides these, there were choice assortments

of Cypripediums, Dendrobiums, Odontoglossums, Oncidiums, Lælias, Cattleyas, &c. In passing to the succession Pine stove I could not help admiring a large bush of Camellia Donkelaari growing outside close to the door. It produces hundreds of flowers during the season. The succession Pine stove is a mixed house. The bed in the centre was filled with a healthy clean stock of Ripley Queens. The front and back stages were occupied with large batches of Calanthes, Gardenias, Pancratium fragrans, and other plants. Melons and Cucumbers were growing in pots, and the Vines trained thinly at a proper distance from the roof. Both Melons and Cucumbers were bearing good crops, and seemed to luxuriate in the same atmospheric treatment. Part of the roof at one end was covered with a large Stephanotis, which was flowering freely.

Mr. Harris is a successful Pine-grower, and has won many first prizes at the London and other large shows in classes where there is strong competition. The plants in the fruiting stove were in the best of health, dwarf and stocky, and all of them swelling off large well-balanced fruits, which any grower might be proud of. Melons and Figs in pots are grown in this house too, and fruit well. The variety of Melon grown generally here is Highcross Hybrid—a dark green-flesh of great depth and of excellent flavour, and the Fig is the Singleton variety. The latter is a perpetual bearer. It is small, but finely flavoured, and much appreciated by the family. The plants are taken outside for a few months to rest, and then brought inside again. Part of this house was covered with Stephanotis and other climbers.

Next to this is a cool Orchid pit containing some good plants of Epidendrum vitellinum majus, Odontoglossum Alexandræ, O. Pescatorei, O. Rossii majus, and many others in fine condition.

Vines, like Pine Apples, are extensively grown here. The early house is filled with Black Hamburgs. The Vines are planted in the outside border, and in Mr. Harris's experience they do much better when planted outside than they do in inside borders. They were bearing a good crop of medium-sized bunches, which were ripe and highly coloured. Shelves are fitted up in all the vineries for forcing Strawberries. A great quantity of Strawberries are forced annually, the varieties being principally President, Sir C. Napier, and Keens' Seedling.

The second vinery is planted with Muscat of Alexandria, Cannon Hall Muscat, and Alnwick Seedling, and the third is filled with Black Hamburg. The latter was partly occupied with Peach trees in pots, which were being grown for trial. They consisted of such varieties as Royal George, Early Beatrice, Stirling Castle, and others. Besides these were a number of Tomatoes growing in 10-inch pots, and a large Brown Turkey Fig tree in a box which completely filled one end of the house.

The fourth vinery is all of Muscats. The Vines were carrying a heavy crop of well-set fruit, which were ready for thinning. Mr. Harris uses no artificial means to set the fruit, and it never fails to set well.

The fifth house is planted with Lady Downe's Seedling. The house is used in the early part of the season for growing Tea Roses, Fuchsias, and other plants before the Vines have made much progress. The Vines in all the houses were clean and healthy, and bearing good crops in different stages of growth.

"I have had pleasure in describing many fine places in South Wales and elsewhere, but few of my peregrinations have afforded me more satisfaction than that which led me to Singleton, and afforded me the opportunity of inspecting its interesting collections under the guidance of its genial and intelligent custodian, Mr. Harris.—A. PETTIGREW, *Castle Gardens, Cardiff*.

GRAPE-GROWING AT BATH.

ALLOW me to say that Mr. Taylor's explanation is perfectly satisfactory. I can understand the Vines on the north-east side of the house not ripening well, and having to be cut back in consequence, and I make no comment on the wisdom of erecting a vinery with the aspect on one side; but what prompted me to put the question to Mr. Taylor was the statement of "W. I." that "all the Vines made most satisfactory growth," by which I understood that they grew and ripened well. It appears now that their progress was as unsatisfactory as it could possibly be to an extension trainer.—J. S. W.

MR. SMEE'S ORCHIDS IN AND OUTDOORS.

As is well known, Mr. Smea has given a number of his Orchids a somewhat lengthy sojourn in the open air during the past two years. The results have been such as to justify him in subjecting several plants to the same treatment this season, and nearly a thousand are now outside, the majority of them having been out since the middle of June, and will remain for a few weeks longer. The majority are placed on latticework rafts, supported a few inches above the water of the embowered streams that meander through his garden; a few are suspended from trees, and the Dendrobiums, with some Epidendrums, are in the full sun. The majority of the Dendrobiums were not put out till they had made about three-parts of their growth; this has been completed in the open, the pseudo-bulbs having ripened admirably, some of *D. nobile* and *D. Wardianum* showing well for bloom.

Many of the plants have evidently enjoyed the change, all those enumerated below being in the most satisfactory condition. The Odontoglossums are especially healthy, with fine bronzed pseudo-bulbs, extremely vigorous growths, and a few stout flower stems showing. These plants are not large, but it is not easy to imagine any in better condition. It must be remembered, however, that there are few gardens containing positions so peculiarly suitable for these plants as in the Grange Garden at Hackbridge.

The following are a few of the Orchids that have made vigorous growth in the open air:—*Ada aurantiaca*, *Cattleya citrina*, *Colax jugosus*, *Cypripedium insigne*, *Disa grandiflora*, *Epidendrum evectum*, *E. xanthinum*, *Lælia majalis*, *Lycaste Deppei*, *L. plana*, *L. Skinneri*, *Maxillaria grandiflora*, *M. venusta*, *Mesospinidium vulcanicum*, *Odontoglossum Alexandræ*, *O. bictionense*, *O. Cervantesi*, *O. cordatum*, *O. coronarium*, *O. gloriosum*, *O. Halli*, *O. nebulosum*, *O. Oerstedii*, *O. Pescatorei*, *O. pulchellum*, *O. radiatum*, *O. ramosissimum*, *O. roseum* (flowering), *O. Rossi majus*, *O. triumphans*, *Oncidium aurosum*, *O. concolor*, *O. crispum*, *O. Forbesi*, *O. macranthum*, *O. Marshalli*, *O. serratum*, *O. tigrinum*, *Sophranitis grandiflora*, *Trichosma suavis*, *Vanda carulea*, this latter producing wonderfully stout roots.

The Orchids under glass are looking extremely well. In one house about a dozen plants of *Vanda Sanderiana* are getting well established, and the *Phalænopses* have improved greatly since they were suspended over a bed carpeted with trailing stove plants. The following are now flowering in the collection:—

<i>Brassavola nodosa</i>	<i>Miltonia Regnellii</i>
<i>Cattleya Gaskelliana</i>	<i>Odontoglossum Alexandræ</i>
<i>labiata</i>	<i>bictionense</i>
<i>Leopoldi</i> (fine spikes)	<i>cordatum</i>
<i>Calogyne cristata</i> Lemoniana	<i>grande</i>
<i>pandurata</i>	<i>hastilabium</i>
<i>speciosa</i>	<i>Pescatorei</i>
<i>Cypripedium Harrisianum</i>	<i>roseum</i>
<i>Lowi</i>	<i>Schleiperianum</i>
<i>Lælia pumila</i>	<i>Oncidium aurosum</i>
<i>elegans</i>	<i>Batemanii</i>
<i>Lycaste Cobbiana</i>	<i>crispum</i>
<i>Smeana</i>	<i>dasytyle</i>
<i>Masdevallia chimara</i>	<i>flexuosum</i>
<i>amabilis</i>	<i>linguiforme</i>
<i>Davisi</i>	<i>Saccolabium guttatum</i>
<i>Harryana</i>	<i>Sobralia macrantha splendens</i>
<i>Houtteana</i>	<i>Satyrion aureum</i>
<i>Normani</i>	<i>Thunia alba</i>
<i>Veitchiana</i>	<i>Vanda Batemani</i>
<i>Mesospinidium vulcanicum</i>	<i>Warszewiczella Wendlandi</i>

WAKEFIELD CARNATION AND PICOTEE SOCIETY'S SHOW

The following awards were made by the Judges, Messrs. T. Bower, Little Horton Green, Bradford; and H. Ives, Wakefield, with the varieties arranged as represented.

PAN OF TWELVE CARNATIONS, NINE AT LEAST DISSIMILAR.

First, Mr. T. Madock, gardener to T. Ramskill, Esq., Lofthouse Hall.

Mars	Sybil	Lord Napier
Master Fred	J. D. Hextall	Sportsman
Stanley Hudson	Sarah Payne	Admiral Curzon
Mayor of Nottingham	Annihilator	Lord Milton

Second, Mr. George Lumb, Kirkgate, Wakefield.

Seedling	Lord F. Cavendish	Seedling
Lord Milton	Seedling	Seedling
John Hines	Benjamin Ives	Seedling
Harry Ives	Seedling	Seedling

Third, Mr. George Gill, Eastmoor, Wakefield.

Juno	Admiral Curzon	Master Bowen
Sportsman	Lord Milton	Sportsman
Squire Meynell	Edward Adams	Dolly Varden
Admiral Curzon	Dr. Cronin	John Hines

Fourth, Mr. J. Steel, Eastmoor.

Fifth, Mr. W. Wilson, Eastmoor.

PAN OF TWELVE PICOTEEES, NINE AT LEAST DISSIMILAR.

First, Mr. T. Madock.

Her Majesty	Master Norman	Prince of Wales
Lady Holmesdale	Master Nichols	Mrs. Rudd
Clara Penson	Mrs. Rudd	Tinnie
Lady Holmesdale	Ann Lord	Rev. F. D. Horner

Second, Mr. George Lumb.

Lady Holmesdale	Miss Sharpley	Fanny
Mrs. Gibbs	Nymph	Lady Holmesdale
Mrs. A. Chancellor	Dr. Epps	J. B. Bryant
Mrs. Summers	Mrs. Gladstone	Seedling

Third, Mr. George Gill.

Mrs. Dodwell	Mrs. A. Chancellor	Brunette
Mrs. Rudd	J. B. Bryant	Lady Holmesdale
Alice	Thos. Williams	Alice
J. B. Bryant	Master Nichols	Lady Holmesdale.

Fourth, Mr. J. Steel.

PAN OF SIX DISSIMILAR CARNATIONS.

First, Mr. T. Madock.

Master Fred	Sarah Payne	Lord Milton
Crista Galli	J. D. Hextall	Admiral Curzon

Second, Mr. George Gill.

John Hines	Sportsman	Edward Adams
Dr. Cronin	Dr. Symonds	Lord Milton

Third, Mr. W. Robinson, Wrenthorpe, near Wakefield.

Rifleman	John Ball	Clipper
Duke of Grafton	Ascendant	James Merryweather

PAN OF SIX DISSIMILAR PICOTEEES.

First, Mr. T. Madock.

Lady Holmesdale	Clara Penson	John Smith
Brunette	Miss Wood	Ann Lord

Second, Mr. W. Robinson.	
Mrs. Gibbons	J. B. Bryant
Miss Turner	Beauty of Cheltenham
Third, Mr. George Gill.	
Lady Holmesdale	Zerlina
Brunette	J. B. Bryant
Alice	
Edith Dombrain	

CLASS FLOWERS, EIGHT DEEP.

Scarlet Bizarres.

1, Admiral Curzon ...	T. Madock	5, Admiral Curzon ...	G. Gill
2, Mars	do.	6, George	J. Steel
3, Admiral Curzon ...	G. Lumb	7, do.	J. Hardwick
4, do.	do.	8, do.	do.

Crimson Bizarres, eight deep.

1, J. D. Hextall	T. Madock	5, Lord Milton	J. Steel
2, do.	do.	6, do.	do.
3, Seedling	G. Lumb	7, do.	G. Gill
4, J. D. Hextall	W. Wilson	8, do.	do.

Pink and Purple Bizarres, eight deep.

1, Sarah Payne	T. Madock	5, James Taylor	Geo. Gill
2, Seedling	G. Lumb	6, do.	W. Wilson
3, J. D. Hextall	W. Wilson	7, do.	J. Steel
4, Sarah Payne	T. Madock	8, do.	Geo. Gill

Scarlet Flakes, eight deep.

1, Sportsman	T. Madock	5, Seedling	Geo. Lumb
2, Clipper	do.	6, Wm. Mellor	do.
3, Sportsman	G. Gill	7, Dan Godfrey	W. Robinson
4, Dan Godfrey	J. Steel	8, Sportsman	G. Gill

Rose Flakes, eight deep.

1, Sybil	T. Madock	5, Seedling	G. Lumb
2, Jas. Merryweather	W. Robinson	6, Rose of Stapleford	G. Gill
3, Seedling	G. Lumb	7, Geo. Lumb	J. Wilcock
4, do.	T. Madock	8, Rose of Stapleford	G. Gill

Purple Flakes, eight deep.

1, Squire Meynell ...	W. Robinson	5, Vicar of Wakefield	G. Lumb
2, Sarah Payne	T. Madock	6, Squire Meynell ...	T. Madock
3, Squire Meynell ...	W. Robinson	7, Master Douglas	Geo. Gill
4, do.	W. Wilson	8, Squire Meynell ...	W. Wilson

PICOTEES.

Heavy-edged Red or Scarlet, eight deep.

1, Miss Turner	W. Robinson	5, Picturata	G. Gill
2, J. B. Bryant	G. Gill	6, Brunette	T. Madock
3, John Smith	T. Madock	7, J. B. Bryant	G. Lumb
4, J. B. Bryant	J. Hardwick	8, Mrs. Dodwell	W. Wilson

Light-edged Red or Scarlet, eight deep.

1, Thomas Williams	Geo. Gill	5, Grosteeen	W. Robinson
2, do.	T. Madock	6, Thos. Williams ...	G. Gill
3, do.	Geo. Lumb	7, Violet Douglas ...	W. Wilson
4, Grosteeen	W. Robinson	8, Miss Small	J. Steel

Heavy-edged Purple, eight deep.

1, Miss Summers	G. Lumb	5, Zerlina	G. Gill
2, Mrs. A. Chancellor	G. Gill	6, Norfolk Beauty ...	J. Hardwick
3, Alliance	T. Madock	7, do.	do.
4, Zerlina	W. Wilson	8, Picco	J. Wilcock

Light-edged Purple, eight deep.

1, Clara Penson	T. Madock	5, Fanny	Geo. Lumb
2, Master Nichols ...	do.	6, Mary	J. Hardwick
3, Ann Lord	W. Robinson	7, Fanny	Geo. Lumb
4, Master Nichols ...	do.	8, Mary	Geo. Gill

Heavy-edged Rose or Salmon, eight deep.

1, Lady Holmesdale	G. Gill	5, Fanny Helen	J. Steel
2, Mrs. Holdsworth	G. Lumb	6, Lady Holmesdale	G. Lumb
3, Louisa	W. Robinson	7, Mrs. Rudd	T. Madock
4, Edith Dombrain	G. Gill	8, Miss Wood	J. Wilcock

Light-edged Rose or Salmon, eight deep.

1, Mrs. Allcroft	T. Madock	5, Seedling	Geo. Lumb
2, Beauty of Plumstead	G. Gill	6, Miss Wood	T. Madock
3, Miss Wood	do.	7, do.	W. Wilson
4, Beauty of Plumstead	G. Lumb	8, Beauty of Plumstead	J. Hardwick

Sels, eight deep.

1, Mars	Geo. Lumb	5, Sportsman	G. Gill
2, Sportsman	G. Gill	6, Seedling	J. Steel
3, Seedling	Geo. Lumb	7, Dan Godfrey	do.
4, Rose of Stapleford	J. Hardwick	8, Seedling	J. Hardwick

Premier Carnation, Master Fred, T. Madock; Premier Picotee, Lady Holmesdale, T. Madock.—J. WILCOCK, Hon. Sec.

JUDGES AND THEIR WORK.

A CORRESPONDENT calls attention in your last to the way some Melons are treated at shows, and another complains of some very indiscriminate judging at Exeter. Of late I have been taking notice of how judges are

appointed at many shows, and I am not surprised that many of them make mistakes. At our county show some of the men who judge fruit and vegetables have to my certain knowledge never had charge of good fruit houses or a good vegetable garden. Their knowledge of plants and cut flowers may not be disputed, but their judging of fruit and vegetables is all a farce. Not very long ago they gave the first prize in a Black Hamburgh Grape class to three bunches of Black Alicante which one exhibitor vowed he would "cheek them with," and he did. There was a class for other Blacks besides Hamburgs, and I verily believe that had there been a good example of the Hamburgh amongst these it would have had the first prize.

Many good growers of vegetables have ceased staging at the Show in question. The largest and coarsest Potatoes are almost sure to be placed before those of finest quality of tubers. I suppose the judges think that by "going in" for size alone they are sure to please some—those who have the prizes for instance—but the system is entirely wrong, and is sure to have an injurious influence on all shows where the judging is done in such a manner.

I think it is probably on the score of economy that such men are appointed as judges. Some florists who may be at the show think they are obliging the society by doing the judging for nothing, their knowledge of the subjects on which they adjudicate being a secondary matter. Of late I have known men, who grow nothing but plants, bring their exhibits to shows, and as the officials thought they had no connection with the fruit and vegetables they might as well judge them, and they gladly do it for nothing, hence the glaring mistakes we often find in these sections. "Who are your judges?" I have sometimes asked, and the reply was, "Oh! no one in particular; So-and-so is bringing plants and he will do it," and so the system goes on, and that, too, in connection with many societies which could very well afford to secure the services of qualified men.

At a large show in the west of England the other day I heard a visitor volunteer to judge the fruit, and to my knowledge this youth never had even a subordinate charge of fruit-growing of any kind. He would have got on, too, as the officials knew no better until I protested, not on my own account, but on behalf of exhibitors generally, and this is why I am writing now. It may be economy to work in this fashion, but it certainly is not satisfactory, and the one should be striven for as much as the other. It is all very well to try to make shows pay, but what is saved in this way will soon be lost in the standing of the show, as good growers will not compete where men profess to judge who know little or nothing of the products. I have no doubt many of your readers will have known of similar cases to those I have stated. Exhibitors, managers, and especially in cases where there are practical gardeners on the committee, should see to this matter, as this cheap makeshift system of appointing judges will ultimately tell more than anything against a show.—A KITCHEN GARDENER.

CHARLES TURNER MEMORIAL.—The promoters will hold a meeting in the conservatory of the Royal Horticultural Society at the conclusion of the business of the Floral Committee on Tuesday next at 12.30 P.M. to appoint a sub-committee to manage the details of the "Memorial," and to approve a circular that has been prepared for distribution. Subscriptions to the fund may be forwarded to the Treasurer, H. M. Pollett, Esq., Fernside, Bickley, Kent.

— SCORCHED MUSHROOM BEDS.—We have heard of Mushroom beds that have been frozen hard in the winter yet have produced abundant crops on the return of mild weather in the spring; but not until recently did we hear of them "standing fire." During the late hot weather, Mr. Holmes, the gardener at Sister's House, Clapham Common, in burning some rubbish, found, on his return to the fire, that it had extended to an outdoor Mushroom bed in bearing, burning all the covering, cooking the Mushrooms, and scorching the surface. The bed, as he thought, was ruined, but he has since been gratified to find Mushrooms "springing up in all directions," and the bed is expected to be as productive as others invariably are in the same garden.

— A SIMPLE method of ENTRAPPING WOODLICE is practised by Mr. Holmes, or was, before he caught them all. They infested his beds, and did much damage, baffling all efforts to subdue them in the stereotyped way of poisoned baits and the like. The natural habits of the pests were observed, and congenial haunts provided. These consist simply of two old dirty half-decayed boards placed face to face on and by the sides of the beds, and covered with litter. Several pairs of boards 5 or 6 feet long, 8 or 9 inches wide, were used. In the morning the

space between them was crowded with woodlice, which were taken away as if in a trough, and jerked into the water tank. It was computed that about a "bushel of the beggars" were drowned, and the pest was practically annihilated. New boards are of no use, only old ones considerably decayed forming effective traps.

— NESBITS' VICTORIA TOMATO is admirably grown and much appreciated for dessert in Mr. Major's garden at Cromwell House, Croydon. The plants are grown in pots, no growths being permitted on the main stem except the huge bunches of fruit and the main leaves. The clusters bear forty or fifty crimson Plum-like fruits each, and have a beautiful appearance. The quality of this variety is considered to surpass most others, and it is more esteemed than any for the purpose in question. Hackwood Park Prolific is found the best large variety, and plants in pots are grown 15 feet high with thick stems like Vines, fruits having been gathered from them exceeding a pound in weight. Mr. Wright, the gardener, appears to know the right way to grow Tomatoes.

— HE does not quite agree with remarks that have been published rather derogatory of the merits of PEN-Y-BYD VEGETABLE MARROW, which he finds extremely productive, the fruits of the right size for cooking whole, and are then considered superior in quality to the old White, as usually sliced before cooking.

— IN the same garden the NIGHT-BLOOMING CEREUS has recently been a feature of interest, the scientific attainments and resources of Mr. Major having enabled him to photograph a bloom with the aid of the magnesian light.

— ONE of the brightest of edging plants for flower beds in the Chiswick Gardens of the Royal Horticultural Society is DEAN'S LUSTROUS TROPÆOLUM. The plant is of compact growth, having small, bluish green foliage, and is covered with rich crimson scarlet flowers of good form and great substance. It seems to have enjoyed the dry weather, and has been extremely effective all through the season.

— THROUGH the kindness of Mr. C. Orchard, of The Gardens Coombe Leigh, Kingston-on-Thames, we have been favoured with fruit of PYRUS VARIOLOSA, which was grown in the garden of Duncombe Shafto, Esq., of Ham Common. It is a pretty, Pear-shaped fruit, 1 inch in diameter, and of a bright mahogany colour. The stalk is 1 inch long, and it has a large open eye. When cut the flesh is red and tasteless, but it soon bleets, and then it has somewhat of the flavour of the Sorb but much sweeter, and consequently rather sickly. It is a native of Nepaul, where the tree grows to 40 or 50 feet high, but in this country it rarely attains to more than 10 or 15 feet, and is ornamental.

— "A READER" requests us to publish the following on MANURE FOR STRAWBERRIES:—"Being a grower of about 3 acres of Strawberries, and farmyard manure in my district being very scarce, and also having to cart it nearly four miles, I shall be much obliged if any friend will kindly inform me of the best substitute to carry them through one year only, and when to apply it."

— REFERRING to TRENCHED AND UNTRENCHED GROUND, a correspondent writes:—"Perhaps your correspondent, Mr. Iggnlden, would kindly tell me how to grow Raspberries. I have a bed of the best kind planted according to his plan of not trenching, but plenty of rich cow manure, the ground never dug, between the plants, but top-dressed heavily. Now for four years I got plenty of very small fruit in my vegetable garden. I have good produce in trenched ground and scarcely any in the untrenched portion."

— AT a meeting of the Council of the Royal Caledonian Horticultural Society, held on August 14th, 1885, it was resolved to hold a SPECIAL EXHIBITION AND CONFERENCE ON APPLES AND PEARS, in connection with the Society's Winter Show, in the Waverley Market, Edinburgh, on the 25th and 26th November, 1885. While collections of Apples and Pears are solicited from all parts for comparison and instruction, the chief object of the Conference is to utilise the favourable opportunity presented by the fine crop this year for the purpose of gaining information about the Apples and Pears grown in Scotland, comparing their merits, and correcting their nomenclature. All fruit-growers, especially in Scotland, are therefore invited to send as complete collections as possible of the Apples and Pears grown in their district; and as the object is solely educational, there will be no competition and no prizes. It is not necessary that the fruit should be grown by the sender. No

limit will be put upon the number of kinds which any contributor may desire to send; but the number of each variety should be from two to four, according to circumstances. The Council are anxious to procure as complete representations as possible of the Apples and Pears grown in each district, and each variety should be distinctly labelled, with the name or names under which it is grown in the locality. It is also most desirable that each collection be accompanied by all the information possible about the climate, altitude, exposure, soil, stocks, method of cultivation, and other particulars, which will be of much value to the Committee in drawing up their report. For this purpose forms will be supplied on application to the Secretary. The specimens being strictly for examination and instruction, they must necessarily be at the disposal of the Council where required. Intending exhibitors must give notice to the Secretary or Assistant-Secretary, in writing, not later than Monday the 16th November, stating the number of varieties to be exhibited, and the amount of space that will be required. Collections of fruit may be consigned to Mr. William Young, Assistant-Secretary, 18, Waverley Market, Edinburgh, and delivered there on or before Friday, 20th November. The Council will pay the carriage of fruit and take all possible care of it, and will also see that it is properly staged for the inspection of the Committee; but they will not be held responsible for any error, damage, or loss of any fruit consigned to them. Exhibitors staging their own fruit can do so on Tuesday, 24th November; and all must be staged and the Hall cleared for the Committee by ten o'clock on the morning of Wednesday, 25th November. Each exhibitor will receive free tickets of admission to the Exhibition for himself and such number of assistants as the Council may deem necessary.

HERBACEOUS PLANTS.

YOUR correspondent, "N. R." at page 162 is evidently in error respecting *Inula glandulosa* and its being a "beautiful blue." Your correspondent, "D., Deal," has described the true plant in the last issue of the Journal as having orange yellow flowers. It is not only perplexing, but it is difficult to reconcile the statement of "N. R.," firstly in the beautiful blue of the *Inula*, and secondly the "enormous mass of Comfrey-looking foliage." The *Platycodon*, as stated by "D., Deal," and *P. grandiflorum* in particular, is a fine blue at this time; the group comprises blue single and double, and white in single and double forms also. Not strictly double, perhaps, but with a multiplicity of petals, and also a striped form. The Caucasian *Scabious*, *S. caucasica*, and the variety *connata* are blues of a soft lilac shade, and stand in the front rank among late summer and autumn perennials, producing their lovely flowers, which are 3 inches across, in great profusion; but there is nothing of the Comfrey in the foliage of these. Blue again may in a measure be found in *Aster amellus* and its Bessarabian variety, both fine perennials of compact habit; plants which in a mass would prove most telling, having a far better effect than could possibly be produced with *Liatris spicata* under the most favourable conditions, and which at the best is a very third-class plant. In *Anchusa italica* we have a grand blue. At this time, however, it is on the wane, and is at its best during June and July. At the present moment I cannot call to mind any plant having flowers of a beautiful blue, and the enormous mass of Comfrey-like foliage. Indeed, apart from the *Anchusa* and *Symphytums*, there are few possessing this foliage. Perhaps "N. R." will describe the plant he refers to or forward specimens to the Editor for verification. At the present time, consequent upon the recent introduction of many genuine and first-rate novelties, there are numbers of very fine perennials—more probably than at any other period, and which may be had at moderate prices, so that there is no necessity for third-class plants to occupy positions where those of superior merit may be seen to advantage. Speaking of *Anthericum* in his concluding remarks, "N. R." seems doubtful as to what species he is alluding to, and which, from his description, I rather suspect is *A. graminifolium*, and neither *A. Liliago* or *A. Liliastrium*.—E. JENKINS.

REMARKS ON JUDGING GRAPES.

AT the outset I wish to point out that I am not a discontented exhibitor, quite the reverse being the case, but I claim my right as an Englishman to have a grumble when the opportunity offers; and if my grumbling contributes, in a measure, to the correction of what I hold to be an error of judgment, so much the better. Of late years it has become the fashion among the compilers of prize schedules to offer prizes for Black Hamburgh, and also for any other black variety, with corresponding classes for Muscat of Alexandria and any other white sort. No one can find fault with the encouragement given to the most popular black and white varieties, these being respectively Black Hamburgh and Muscat of Alexandria, but it is the ambiguity of the wording of the classes for any other black and white sorts, that leads to so much misunderstanding and so many much-to-be-regretted wrangles in the fruit tents. I am aware that it is usually a difficult matter for those framing the schedules to find sufficient money to offer prizes for any Grapes that may be in season, and as a consequence the judges must be depended upon for deciding on the merits of the various competing sorts, but each schedule might well include a rule to the effect that all Grapes shown should be in season. Then if the judges, during August or early in September, persist in placing Black Alicante before

equally well-grown Madresfield Court, they can easily be proved to have committed a great error in judgment. That such decisions are now becoming of frequent occurrence numerous competitors will gladly corroborate, and the sooner it is stopped the better.

No one, I think, will dispute the fact of the great superiority of Madresfield Court over Black Alicante, more especially as far as quality is concerned, but if the present method of offering prizes, and the plan of judging by appearance, is persisted in, not a few ambitious cultivators will gradually substitute the more easily grown and most showy variety for a Grape considered by many connoisseurs to be superior even to the good old Black Hamburgh. Most Grape-growers are well aware that it is difficult to thoroughly colour the Madresfield Court, and very seldom indeed are they exhibited perfect in every respect. The bunches may be large, the berries extra fine, the flavour excellent, and only the colour a little wanting near the footstalks of the berries, and because of this slight deficiency they are placed second to highly coloured, and perhaps quite sour Black Alicante. Four such occurrences have come under my notice this season, and in only one instance—that at Weston-super-Mare, where Mr. Nash exhibited extra good Alicantes—do I consider the judges exercised sound discrimination. Black Alicante may be grown and perfectly coloured in a Hamburgh house, but the less said about the quality in such a case the less likely are we to offend. Black Alicante is essentially a late Grape, and if ripened during August and September with a plentiful amount of fire heat, they will keep well and give satisfaction to many, say any time during November and December.

Alnwick Seedling, now that the difficulty of expecting a good set is obviated, will also become a formidable rival to Madresfield Court, at least on the exhibition table. This noble-looking Grape colours even more surely than the Alicante; and, as in the case of the latter variety, the berries may be perfectly black and yet extremely sour. It is said to be a very good keeper, but I am afraid this will be found to be a mistake, as in two cases that have come under my notice the berries shrivelled in September and October. It may be the stock on which the rods are worked has much to do with this premature shrivelling, and if this proves to be the case the Hamburgh stock is the offender. With me it is fruiting on the Hamburgh, the latter carrying a crop as usual, thus preserving its individuality, but I have a strong Vine on its own roots for next season's fruiting, and I shall be much disappointed if the fruit fails to keep well. One thing is certain, this variety ought not to be encouraged in the any black class before the end of September. Neither ought the Gros Maroc, nor do I think it will ever figure very extensively on the exhibition stands. According to my experience it is a gross grower, not a free bearer, and the quality is only second rate. I have seen a few good examples of it, but have not tasted any really good.

Black Prince is not often shown nowadays, but, according to the present style of judging, well grown examples of this very poor flavoured Grape would occupy a premier position on the show table, and I have known a case where really well grown Black Hamburgs were placed second to it.

I hold that no other black variety than Black Hamburgh and Madresfield Court should be encouraged during August at least, and this would stimulate the culture of the two best black summer Grapes, as well as prevent the frequent unseemly wrangles which some exhibitors are too ready to commence.

In the case of white Grapes there is less cause to complain, as there is not much to choose between them. As a rule Buckland Sweetwater when well grown secures the first position, but occasionally this is superseded by good, or even fairly good, examples of Golden Champion or Duke of Buccleuch, and as both of these are in season and of superior quality, no one thinks of finding fault with the judges for preferring them. Foster's Seedling, however, I sometimes think rather hardly used, especially when shown in good condition, and yet passed over in favour of the more showy but otherwise inferior Buckland Sweetwater. The latter, both at Weston-super-Mare and Salisbury, was unusually good and fully deserved the premier awards, but in many cases they are unduly favoured at the expense of the better flavoured Foster's Seedling. I would not interfere with the wording of various schedules as far as the any white Grape class is concerned, beyond stipulating that Muscats be excluded. A class being provided for Muscats, not necessarily Muscat of Alexandria, the next should be for white Grapes, Muscats excluded, and this would shut out Canon Hall Muscat, which occasionally finds its way to the exhibition table, from the latter and drive it into the proper class for it. Too often, I am afraid, the flower show committees pay little or no heed to the effect the offering of prizes for certain things has upon the selections and proceedings of competitors, and I am sorry to say what few attempts I have made to correct the wording and arrangement of prize lists have not had any appreciable effect. Two or three practical gardeners ought to be included in every committee, and this would be for the advantage of all concerned.—W. IGGULDEN.

NOTES ON VEGETABLES.

CUCUMBER, CARDIFF CASTLE.—I have grown this variety in a frame for the first time this season, and consider it a most excellent Cucumber, which should be in the hands of all gardeners that have to give a daily supply for salad and kitchen use. I have not yet grown it in the winter season, but judging from its behaviour in a dung frame (and with rather rough treatment, as we had not time just then to give it proper attention), I think it will possibly prove an excellent variety for growing in winter. It is most prolific, of excellent flavour, and the length to which it grows

is all that could be desired for everyday use. We all like to get a good brace of Cucumbers, long and perfectly straight for the exhibition table; but as a rule they go to table sliced, so that it is far better to have two Cucumbers at a foot long than to have one at 2 feet long. So to all those that do not know this variety I would say, Give it a trial. So far as my experience goes, it appears to be more hardy than Telegraph, and is certainly more prolific.

TURNIPS, EXTRA EARLY MILAN.—Gardeners are often asked for vegetables for kitchen purposes when the late crops are exhausted and the early ones are not fit for use. I think the Turnip is as much called for, for soups, &c., as any one thing. I myself have been driven almost to my wit's end to know how to act to satisfy their wants; but in the spring in ordering the seeds I noticed the above variety, and thankful I was. I sowed it on the 18th of February on a warm border, and began to pull good little roots early in April. I made another sowing in March, on a south border, of Extra Early Milan, Early Snowball, and Veitch's Red Globe, and found by doing this they followed well in succession. We had just cleared off the Milan, and the Red Globe was fit for use. We had the Snowball, and this in pretty much at the same time, but we found them very useful. I think everyone should grow the Milan, as it is fitted to act as a "stop gap." I am only offering these remarks to those who may not have tried them, and as I have obtained many valuable hints from the *Journal of Horticulture*, so that it is only fair that I should try to help others by giving my experience through the same medium.—ROBT. D. LONG.

THE HISTORY OF THE CHRYSANTHEMUM.

(Continued from page 160.)

The last French raiser to be mentioned and the most important of all, for he must be known at any rate by name to every grower in this country, is Mons. Delaux. He it is who may proudly consider himself as the rival of Mr. Salter, although it must be distinctly stated that his conquests have been most brilliantly exemplified in the Japanese section, in which Mr. Salter had but little opportunity of working. Mons. Delaux and his son are perhaps of all florists, both English and French, those who have followed up with the grandest success the new road opened up by the introduction of the Japanese Chrysanthemums by Mr. Robert Fortune.

During a period extending over more than eighteen years they have been working and searching at the sacrifice of great cost and labour to produce an assemblage of these plants worthy of a place in the finest collections. It is almost entirely to them that we English cultivators are indebted for the majority of those splendid Japanese flowers which for years past have been, and are continuing to be, imported into this country. In fact, there is hardly an exhibition held here where the smallest stands do not contain some blooms of these eminent florists' raising. It would almost necessitate a volume by itself to give a list of their productions, which comprise Chrysanthemums of every section, but it would be an act of extreme discourtesy were the author not to mention some of the well-known flowers sent out by these gentlemen, especially as he has reason to be grateful for no little useful and interesting correspondence with Mons. S. Delaux fils. Those which have been in cultivation here for some few years past, and generally known, are Agréments de la Nature, Alexandre Dufour, Albert de Naurois, (syn. Albert,) Bouquet Fait, Cœur fidèle, Dolores, Éclatant, Éléance, Émeraude, Étoile du Midi, Flambeau, François Delaux, Général de Lartigue, Gloire de France (wrongly called by some La France), Hiver Fleuri, Ile Japonaise, Isidore Féral, Japonais, Japon Fleuri, Jeanne Delaux (syn. F. A. Davis, wrongly catalogued J. Delaux in many English lists, and thus easily confounded with Jean Delaux, an older and now nearly uncultivated variety), Le Nègre, L'Incomparable, L'Île des Plaisirs, La Charmeuse, La Frisure, Laurence, La Bienvenue (syn. J. Hillier), Le Chinois (syn. Chinaman), M. Delaux, M. E. Pynaert van Geert, Orphée, Rêve de Printemps, Source d'Or, Tricolor (syn. Mr. J. Starling), and many others. Among the importations from this source during the last two seasons the following varieties have been distinguished by having first-class certificates awarded to them—Mons. Astorg, Mons. Tarin, Flamme de Punch, Margot, Beauté des Jardins, Madame de Sevin, Brise du Matin, Mons. Moussillac, Souvenir du Japon, and Fernand Féral.

To an English grower it will seem strange that such a thing as a Chrysanthemum society does not exist in France. Some of the horticultural societies are giving special attention to the flower latterly, but the exhibitions would appear to be few and far between. There was one about 1876 in the south of France, but it was hardly heard of here. Since then there may have been others, but little attention has been paid to them by the English, especially as the French method of culture generally practised is to aim more at the development of a large number of blooms on a plant than the culture of what we know as show flowers.

Last year there was one at Paris and another held under the auspices of the Chalons Horticultural Society, at both of which medals were awarded to the successful competitors. At the latter

place the schedule of prizes was not arranged in a similar way to ours, and was divided into classes in the following manner :—

First section, pot plants.—Group 1.—For the best seedling variety or varieties not yet in commerce.

Second section, group 2.—For the best and largest collection comprising all kinds.

Second section, group 3.—For the finest collection of 100 select varieties.

Second section, group 4.—For the finest collection of forty select varieties.

Second section, group 5.—For the finest Japanese collection.

Third section.—Cut flowers.

Third section, group 6.—For the finest and largest collection comprising all kinds.

Third section, group 7.—For the finest collection of 100 select kinds.

Third section, group 8.—For the finest collection of fifty select kinds.

Third section, group 9.—For the finest collection of Japanese varieties.

Fourth section.—Objects of artistic culture and decoration.

Fourth section, group 10.—For bouquets, baskets, &c., made up with Chrysanthemums.

Fourth section, group 11.—For the best treatise on the Chrysanthemum.

At this Exhibition nearly every French amateur and professional raiser of any standing in the horticultural world took part, and a banquet brought the proceedings to a close. It is curious to note that the cut flowers, which numbered 3000, instead of being exhibited in boxes or show boards, were shown in glass bottles, and so great a stir did the Show create in the town that the local floricultural journal devoted upwards of five pages to the event. There was also a subvention granted by the Municipal Council of the town, a precedent that if acted upon in this country would gladden the hearts of many a grower here. As a consequence of this the Chalons Horticultural Society appointed a Special Committee to organise and conduct an international plebiscite in favour of the Chrysanthemum, and some of the English growers were invited to take part in it, but the result like that held in this country in 1883 can hardly be regarded as an entirely satisfactory or useful one from an exhibitor's point of view. It may prove of some little interest to point out that the Committee in conducting the ballot issued voting papers to the leading cultivators, in which not more than fifty varieties were to be named. The papers on their return were examined by the Committee, and the fifty varieties which received the largest number of votes were selected and arranged in the relative order. The result was as follows :—

Triomphe de la Rue des Châlets
Erectum Superbum
Gloire Rayonnante
Source d'Or
Laciniatum
Fair Maid of Guernsey
M. Planchenau
Bras Rouge
M. Frémy
Madame Clemence Audiguier
Yellow Dragon
La Charmeuse
La Frisure
Souvenir de la Reine Mercédès
La Vierge
Pink Perfection
L'Automne
Sœur Mélanie
Marguerite Marrouch
Perle des Beautés
Fée Rageuse
Père Delaux
L'Île des Plaisirs
Timbale d'Argent
Belle Paule
William Bull

Royal Soleil
Perle des Blanchés
M. Moussillac
Maréchal Soult
M. Roux
Richard Larios
Alexandre Dufour
Fabian de Médiana
M. Crousse
L'Infante d'Espagne
Dr. Audiguier
Flamme de Punch
Aimé Ferrière
L'Incomparable
Reine Margot
M. Delaux
M. Castex
Empress of India
Patrie
Mlle. Cabrol
Lady Selborne
M. Elie
Dr. Masters
M. Astorg
M. Patrolin

In America during the last year or two the Chrysanthemum may be said to have created quite a furor, and our Yankee cousins seem bent upon vieing with the Europeans in their appreciation of it. There does not appear to be any authentic record of the date of the introduction of this plant into the States, but it is said that it was undoubtedly known there in 1825, and there are many varieties now growing in the gardens in Long Island that have been there for upwards of half a century, and are much similar to the varieties before described in the early part of this treatise. Several florists, both amateur and professional, in that great country have raised and distributed new varieties from seed, among whom may be mentioned Dr. Wallcott and Mr. Thorpe. Owing to the great distance, however, that they are from the centre of the Chrysanthemum grow-

ing world is in all probability one reason why they have sent out some kinds but little valued by those who have grown them in Europe, for although the author has had no opportunity of seeing these American productions he learns from both French and English sources that the American varieties leave much to be desired.

This spring another American, Mr. W. K. Harris, is sending out for the first time five new kinds, which may in due course be catalogued in the English growers' lists, and for that reason it is unnecessary to give their descriptions, and those of the other two gentlemen above referred to. Mr. Harris has named his plants Christmas Eve, Mrs. Vannaman, White Dragon, Golden Queen, and W. L. Scheffer. Mr. H. Waterer, an importer of plants and bulbs in the States, announces the offer of twenty-five incurved and Japanese varieties selected in China and Japan, and which bloomed for the first time in that country last season.

If any proof be required that the Chrysanthemum is still as popular as it ever was, and that the love of it has not yet begun to abate, the author can point out instances where tiny plants only 2 or 3 inches high of new varieties have in the early part of this year been distributed by the raisers at the unusually high price of £1 each, a sum perhaps never yet paid for a plant of the Chrysanthemum. And, further, Messrs. Cannell & Sons have received direct from Japan 200 Chrysanthemums, besides the usual complement from the Continental raisers. Mr. N. Davis reports that he has under trial more than 120 distinct new sorts, while the French send out among them 145 varieties of Japanese, Pompon, summer-flowering, and other kinds, all of which they represent to be new and distinct. So great is the demand for our favourite flower that there are nurserymen who devote in some cases the whole, and in others a large part, of their establishments solely to its culture and the testing of the novelties that appear from time to time, at many of which the lover of the Chrysanthemum is invited to attend when the blooming season arrives.

Before concluding it may not be entirely useless to give the reader a list of some of the nurserymen who pay special attention to the growing of the Chrysanthemum, and at the same time it must be borne in mind that plants may be purchased of many others who are, of course, quite as well deserving of notice, but with whom the author is unacquainted, and more ignorant as to the extent of their business in this particular branch.

Mr. W. E. Boyce, Yerbury Road, Holloway, N.; Mr. Wm. Bull, King's Road, Chelsea; Messrs. Cannell & Sons, Swanley, Kent; Mr. N. Davis, Lilford Road Nurseries, Camberwell, S.E.; Messrs. Dixon and Co., The Amhurst Nurseries, Hackney, E.; Mr. Wm. Etherington, Manor House, Swanscombe, Kent; Messrs. T. Jackson & Sons, Kingston, Surrey; Messrs. Laing & Co., Forest Hill, S.E.; Messrs. Mahood & Sons, Putney; Messrs. J. Morse & Sons, Dursley, Gloucestershire; Mr. T. B. Morton, Mouden Bridge Nursery, Darlington; Mr. R. Owen, Boyne Hill, Maidenhead; Mr. W. Piercy, Forest Hill, S.E.; Mr. G. Stevens, St. John's Nursery, Putney; Mr. C. Turner, The Royal Nurseries, Slough; Messrs. Veitch & Sons, King's Road, Chelsea; Mr. T. S. Ware, Hale Farm Nurseries, Tottenham.—C. HARMAN PAYNE.

FRUIT TREES IN POTS.

SOME persons fail, others succeed in growing fruit trees in pots satisfactorily. Mr. George Hawkins, gardener to Col. T. P. Turberville, Ewenny Priory, Bridgend, is one who succeeds. We have seen examples of his skill on more than one occasion. The last was the fruiting spray of Peaches figured, but necessarily much reduced. The fruit was very fine indeed, and the foliage equally so. The grower of the fruit writes as follows :—

"We have two small orchard houses, and grow over ninety trees in pots. The back wall of our lean-to house is also covered with trees, and two Vines occupy part of the roof. I think there is no other way in which so many fruits can be had and so many varieties grown, so as to insure a long season, as having trees in pots. I should advise anyone who may have two houses to devote one to such trees. Half a hundred of my trees can be grown in a small house, as the early ones when gathered are turned out, and the later ones given a little more room, and so on. Cherries come out very early. When all the fruit is gathered the trees can be turned out and the house filled with Chrysanthemums. I have this year gathered 140 Nectarines from one tree in a pot of Rivers' Orange, 100 off one tree of Pine Apple, and 100 Peaches from one of Rivers' Early York. Sixteen-inch pots are the largest used, and but very few of them. We get our trees from Mr. Rivers. I never saw Mr. Rivers or yet the Sawbridgeworth nurseries, but if I ever have a chance to see them I expect something worth the journey.

"My method of culture is very simple. The trees are repotted annually

just before the leaves drop. Soil is taken from waste patches on the roadside, and collected only a week or two before using, and mixed with about a fourth part of its bulk with manure from a Cucumber bed. After potting, the trees are heavily watered, placed close together, and syringed

relied upon as sure croppers in pots. We grow several other sorts, but these would suit any new beginner.

"CHERRIES.—May Duke, Elton, Governor Wood, black and white Bigarreau.

Fig. 36.—PEACHES FROM A TREE IN A POT.

once or twice daily until most of their leaves drop. A little bone manure was mixed with the soil at potting time last autumn, and I have found it answer well. Through summer we use liquid manure water that drains from the dung heap once or twice a week. The following varieties can be

"PEACHES.—Conkling, Hale's Early, Noblesse, Waterloo, Alexandra Noblesse, Dagmar, Early Alfred, Early Rivers, Gladstone, Lady Palmerstone, Osprey, Princess of Wales, Rivers' Early York, and Stanwick Early York.

"NECTARINES.—Downton, Elruge, Galopin, Hardwick Seedling, Pitmaston Orange, Violette Hative, Alhert Victor, Milton, Improved Downton, Lord Napier, Newton, Pine Apple, Rivers' Orange, and Stanwick Elruge.

"PLUMS.—Belgian Purple, Coe's Golden Drop, Denniston's Superh, Green Gage, Lawrence's Gage, Oullins Golden, Reine Claude de Bavay, and Transparent.

"PEARS.—Jargonelle, Beurré de l'Assomption, Beurré d'Arenberg, Beurré Superfin, Souvenir du Congrès, Louise Bonne of Jersey, Beurré Hardy, Marie Louise, Durondeau, Bonne d'Ezès, Pitmaston Duchess, Doyenné du Comice, Duchesse d'Angoulême, Beurré Diel, and Beurré d'Arenberg."

TUBEROUS BEGONIAS AT RATHRONAN HOUSE.

ONE of the places in this locality that Tuberous Begonias are better grown from year to year is at Rathronan House, near Clonmel. A dozen beds are filled in the flower ground, some of the most intensely brilliant colours, such as Lælia, Sedeni, Oriflamme, Vesuvius, and many others, including locally raised seedlings, chiefly remarkable for their floriferousness and compactness of habit. I have seen the best varieties, both single and double, bedded out; but many of those do not do at all so well as those better furnished, though the individual blooms may be finer. So intensely brilliant were some of the beds, for instance, two of Lælia, a deep crimson pink, that some of my gardening friends whom I drove out found it difficult to gaze long on them. So of the orange reds; whites do not seem to be popular for bedding out. Madame Saladin, a yellowish white, very free flowering, I have grown outside for a few years, but it is not showy. If well treated it becomes semi-double.

The variety here is very extensive, and as I frequently see inquiries in the Journal as to really good varieties, I cannot do better than copy the names of some of the best sorts that Mr. Gough has retained, after "weeding out" those inferior.

Doubles.—Miss Wise, soft, full, rosy pink; Mons. Keteleer, this is like the last, and very desirable; Agnes Sorrel, salmon pink; Ophelia, Mdme. Comesse, very fine; Jules Lequin, Marie Lemoine, David M. Home, good; Edith, Alha Plena, best double white; Citrina Plena, and Duchesse de Cambracres.

Singles.—Snowflake, magnificent tinted white, a shade over 6 inches across; Mrs. F. Freeman, very fine; Countess of Kingston, still one of the largest and finest crimson reds; Mrs. Highgate, immense size, scarcely inferior to Mr. Cannell's monsters; Hon. Mrs. Brassey, large rich crimson, that no collection should be without; Sir Stafford Northcote, Ball of Fire, Marquis of Bute, La Rosière, F. E. Laing, Aspasia; and among the earlier-raised varieties still deserving of patronage would be Oriflamme, Trocadero, Progress, Monarch, Mdme. Stella, Souvenir de M. Saunders, &c.

Here the custom is to start early, say in February, and then grow slowly along so as not to allow the plants to get drawn. Much care is required in keeping them over the winter, so as to prevent rotting on the one hand or drying up on the other. Even if no water is given, great risks are run even by laying them under the stage, should the atmosphere of a house be at all moist. In this way, at Cork last year, one of the finest collections in the British Isles were seriously injured, much more than 100 guineas' worth being lost when examined.

The risk is much greater with the newer developments of doubles and semi-doubles coming from MM. Crousse, Lemoine, Keteleer, &c., in France than those raised by Cannell, Laing, and others in this country. Many singles, and some doubles, on the other hand, as Gloire de Nancy, I have known to live outdoors the whole of last winter merely covered with coal ash. Many are under the impression they can get fine Tuberous Begonias from seed. No doubt there are fine strains advertised in your columns from time to time, but if one worth naming was found in 10,000 the raiser would be lucky.—W. J. MURPHY, Clonmel.

ESTIMATE OF VEGETABLES.

PEAS.—The dry season has been very much against these. The late crops are a complete failure, falling a prey to aphides, and the mid-season varieties were badly infested with mildew, whilst the earlies came in quickly and were soon over. Of the earlies, Dickson's First and Best cropped splendidly, producing well-filled pods, bringing 3s. per bushel, and next to this came William I., a good crop of fine well-filled pods, which realised no more, and the crop being fully a fourth less the advantage is considerably in favour of the first named. Veitch's Extra Early was fully a week in advance of the two previously named, and as it gives its crop all at once is a very desirable early variety. It realised double the price of the others per bushel, but it must be borne in mind that its yield was fully one-third less than for them. Early Sunrise (Day's) may be mentioned as having filled its pods well, which it does not always do, and it is fully a week later, though a more telling variety in the pod than First and Best and Kentish Invicta, a blue Pea, ought to be mentioned as a prolific variety, coming in a little later than William I. My selection of the earliest sorts are Veitch's Extra Early as a first crop on warm borders or situations, and then First and Best with William I. for the main supplies, but I by no means wish to disparage the others, as they crop well, and under field culture pay as well as any.

Of the second earlies I find Criterion a fine variety, and where sticks

can be had it is, I think, the most prolific and best in quality of all the second earlies. What better than Huntingdonian and Champion of England? Yes, better by nearly half in crop, and equal in quality; indeed, it is a Ne Plus Ultra of high flavour and heavy cropping qualities. Telegraph beat Telephone hollow; it cropped heavier, and though its pods were not quite so big, its colour and high quality gave it an advantage; anywise, it brought more money. Prizetaker, though green as grass, disappointed; grown along with Criterion it cropped less, and brought less, taking quantity for quantity, and may be classed with such kinds as Hundredfold and Dickson's Favourite, good in their way, but not comparable to Criterion.

Of second earlies of medium height, or 3 feet or so, I give Gladiator first place; it is superior in cropping to Fillbasket, and the quality is excellent. Marvel was very productive, and its quality is excellent. It succeeds Gladiator, being more a main-crop than second early variety. Dr. Maclean did capitally, and it is too good a Pea to be omitted; and that good sort Essex Rival certainly ought not to be passed, on account of its good constitution and productiveness. But I have nothing to record in favour of John Bull nor Robert Penn, Stratagem, and others of like ilk. They please me wonderfully well in the garden, but they do not pay. Veitch's Perfection did not do well, the drought was too much for it, and similar remarks apply to Best of All, which is of the same type. In ordinary seasons I have found them unsurpassed as medium height main crop varieties. The Pea that seems to have done well this season is a kind I have not grown—viz., Albert Victor; it is a large Pea of medium height, great cropper, and not subject to mildew, being highly eulogised by at least one grower for market.

Of the late sorts the only one that cropped at all profitably in the tall kinds was Ne Plus Ultra. It cropped well, and brought 4s. 6d. per bushel, but none seemed to be able to hear the drought, and were soon over. Blue Scimitar I heard of as doing well, but I did not grow it. Culverwell's Giant Marrow did well, but it did not take in the market. Omega was anything but prolific, and a similar remark applies to Sturdy, which, however, for table is much esteemed. Walker's Perpetual Bearer may be placed in the same category as not being paying sorts—not, at least, this season; therefore I give as selections Ne Plus Ultra and Blue Scimitar, the former for sticking, the latter will do without, but I find sticks are necessary for all to have them in perfection, yet they cannot be used in field crops generally.

Evolution cropped well, and certainly is the finest flavoured Pea I have tasted. It is a grand Pea for any purpose. The Wordsley Wonder, which I had for the first time, was a marvel of productiveness, and is a second early, coming in a few days only after the earlies, being a blue wrinkled kind of medium height, about 3½ feet, and the quality is excellent. It is certain to become popular, for it keeps up its character as shown this season, it must take first rank amongst the earliest kinds, if, indeed, it does not supersede them.—UTILITARIAN.

MIXED FLOWER BEDS.

FLOWER beds filled with two or more distinct kinds of plants set out so that the colours of the flowers, though mixed, yet harmonise or contrast, is an old method of bedding which might with advantage be employed more often than it is. Setting aside the obvious usefulness of the system in cases where the supply of the finer bedding plants is below the requirements, we would place the system on the basis of its own merits as a good system. Some of the very prettiest and longest lasting beds we have ever seen have been mixed beds, and although these arrangements lack the massiveness which a block of one colour gives, they nevertheless do not fail in effectiveness, which in reality is the main point.

In commending mixed bedding we must not on that account be supposed to do so at the expense of any other method of filling the beds. The fact is, there is plenty of room in most gardens for many styles of bedding, and in the case of those of more limited extent there is no reason why the same thing should be done year after year without change; so that we would not in any way say a word against the method adopted by anyone to make his flower garden bright. At the same time, it may be worth while to present the mixed method to notice as being as worthy of adoption as any other.

At first sight mixed bedding might be considered as a very simple matter, but it is possible to invest it with more than the simplicity of merely placing out in alternate rows plants of two kinds of flowers. Either that system may be adopted, or a modified one of having each plant in the row following in alternate order according to the kinds used. For some things that system is a very good one, and especially where the plants employed form a striking contrast. Even where the colours harmonise a simple mixing of the plants as above may be employed, but it does not follow that we should confine ourselves to that method of planting alone. Much better effects are produced by forming a groundwork of one colour, and dotting in it another kind of plant. The groundwork may form such a slight relation to the general arrangement, as that each main plant may be divided from its neighbour merely by a narrow band. Or it may be that the groundwork takes up the whole of the bed with the exception of a few dot plants, which give character to the whole. However, it must be observed that the principle of mixed bedding is in all cases present. Two things to be avoided in mixed bedding are insipidity and glaring colours. On the whole the insipid arrangement is preferable to the other even when judged on their individual merits, but the former can also in most cases be improved and made presentable by the addition of a few plants of bright colouring, whereas the other always remains intolerable. The most extreme example

of bad taste we have yet seen was in a mixed bed of dark-leaved Beet and *Centaurea ragusina*. Yellow and black might prove even worse, but the addition of a few pink or red Pelargoniums would help the last named, whereas in the other case they would not. Purple and yellow in combination may either be a failure, or, on the other hand, prove a most striking success. If the purple be deep, as in *Tory Viola*, and yellow of the golden hue of *Pansy Golden Queen* of England, one might hope for success, but if either the purple or the yellow were light in shade, then they would be vulgar. And so a light yellow in combination with *Vesuvius Pelargonium* would be offensive, while a deep yellow with a crimson variety like *H. Jacoby* would be extremely effective. An illustration of an insipid bed would be *Christine Pelargonium* with a light yellow *Viola*. If the *Viola* used were a deep yellow its character for insipidity would be removed, while were a deeper shade of pink used with the deeper yellow, a really effective mixture would be the result. A very light shade of blue in combination with white gives a bed without character, but if the white is produced by a white-leaved red-flowered Pelargonium, then the result is completely changed for the better.

Before giving some examples of good combinations, it may be noted that the bands and edgings to beds alter the general tone of the arrangements considerably. Not only may the general effect be improved, but, on the other hand, a really effective arrangement may be entirely nullified by its setting. This is true in all kinds of bedding, but holds with increased force in the kind under discussion. The most pleasing of all combinations in mixed beds are produced by soft colour shades and white. Perhaps one of the very best is composed of a groundwork of *Königa variegata* dotted rather thickly with Pelargonium Flower of Spring. The *Königa* is pegged down so that the Pelargonium is just a little taller when the little heads of the former make their appearance. A band of *Iresine Lindenii* or *Colens Verschaffeltii*, with a white-leaved plant for an edging, help to make a pretty and effective bed. Dwarf *Ageratum* with the same Pelargonium planted rather widely apart, a band of white enclosing the central mass and a deep blue outside the white, with an edging of grey, makes a good bed. *Viola Duchess of Sutherland* substituted for the *Ageratum* is perhaps even better. *Vesuvius Pelargonium* pegged down, mixed with *Viola Alpha*, with a grey or white edging, forms a rich combination.

We have this season, in a set of four beds, the two *Calceolarias Kayi* and *General Havelock* in mixture. The yellow *Kayi* should be planted as one to three of the above rich brown variety. The band in this instance is *Lady Macdonald Lobelia* and grey *Sedum* for an edging. *General Havelock* and *Master Christine* in equal number with a band of *Viola Sovereign*, deep yellow, makes a very good bed. *Mangle's Variegated Pelargonium* and *Wave of Blue Lobelia* together, the latter in the proportion of five to ten for one of the former. The same *Lobelia* and *L. Lady Macdonald* in equal number thinly dotted with single plants of *Chamæpence dicantha* and banded with the striped-leaved *Polemonium*. Either of these *Lobelias* planted in small intersecting circles with a good plant of *Lass o' Gowrie Pelargonium* as a dot plant in each circle will make thoroughly good beds. Numerous modifications may be carried out, especially by employing decorative plants, standard *Fuchsias*, *Abutilons*, &c., as centre plants, or dotted thinly about over the beds according to their size or the taste of the cultivator. For the past year or two we have found a few of the best dwarf single *Dahlias* very useful for mixed bedding. These must not be planted closer than 2 yards apart, and the groundwork may be any flower or flowers which will harmonise well with the shades of yellow, red, and rose, and of white, which prevail in these. Of course they are suitable alone for very large beds or long borders.

Old specimen *Fuchsias*, double Pelargoniums, *Humea elegans*, *Tuberous Begonias*, &c., dotted thinly over any very poor bed at once effects a complete transformation. The only matter of consequence to be kept in mind is to use these very sparingly, so that each can be seen all round, and further, not to mix Pelargoniums with any of the others, but to keep each kind in a bed by itself.—B.

HORTICULTURAL SHOWS.

TROWBRIDGE.

THE Exhibition of this very old Society continues to be surprisingly attractive, not less than 15,000 people having paid for admission, many of these coming a considerable distance by road or rail from the surrounding country. For thirty-six years this Society has been established, and, as one very old exhibitor remarked, but very slight alterations have been made in the prize schedule for several years past. As a consequence, the Show is more remarkable for the quantity rather than the quality of the plant exhibits; and, why when there are so many much better shows held in the neighbourhood, the Trowbridge Show continues so exceptionally attractive remains a mystery. *Fuchsias* are always shown in splendid condition, being in fact second to none in the country, and for these fairly liberal prizes are offered. The specimens are all very tall and floriferous, there being nothing stiff or formal about them. Mr. J. Lye, gardener to the Hon. Mrs. Haye, Lavington, who for a long time has made *Fuchsias* a specialty, had this year to be satisfied with the third prize for both six varieties and four varieties; Mr. J. Matthews, gardener to W. R. Brown, Esq., Trowbridge, and Mr. H. Pocock, gardener to J. P. Haden, Esq., Trowbridge, being respectively first and second with six varieties; and J. Matthews and G. Tucker, gardener to Major W. P. Clark, Trowbridge, first and second with four plants.

Owing to the smallness of the prizes offered, the classes for stove and greenhouse plants, though well filled, attracted nothing from a distance, and as a consequence the quality was somewhat inferior. There were

medium sized and fairly well flowered specimens of *Allamandas*, *Clerodendrons*, *Ixoras*, *Dipladenias*, *Bougainvilleas*, and *Ericas* in competition, and the principal prizewinners were Messrs. G. Tucker, H. Pocock, J. Matthews, H. Clack (gardener to C. E. H. A. Colston, Esq., Devizes), G. Pym, gardener to Mrs. Gouldsmith, Trowbridge, W. G. Drummond, Bath, and J. Lye. Ferns and Mosses are always well shown at Trowbridge, the groups being more noteworthy on account of the healthy state of the plants than for their size. All the best show varieties of *Adiantums*, *Gymnogrammas*, *Davallias*, *Dicksonias*, and other popular kinds were well represented; and the prizewinners were Messrs. G. Tucker, first, Henry Clack and G. Coke (gardener to A. P. Stancombe, Esq., Trowbridge), equal seconds, and H. Pocock third. There were also various other classes for Pelargoniums, Heaths, Coleus, Achimenes, Cockscombs, Begonias, Balsams, Verbenas, and Petunias, many of which might safely be cut out and the prize money diverted to the other classes.

Cut flowers are always largely shown at Trowbridge, and this year, notwithstanding the unfavourableness of the season for several kinds, the competition was even better than ever. Messrs. Cooling & Son, Bath, and Keynes, Williams & Co., Salisbury, divided the honours for cut Roses; Mr. J. Mattock, Oxford, being a good third in both cases, all showing a really excellent lot of blooms. Messrs. Keynes, Williams & Co. were first in both large classes for *Dahlias*, and they also obtained certificates for three novelties, but on the whole the blooms were scarcely up to their well-known form. Other successful exhibitors of *Dahlias* were Messrs. T. Hobbs, Bristol, G. Humphries, Kingston Langley; and G. Horsall, Bath. *Asters*, *Verbenas*, Pelargoniums, and other cut flowers were also well shown. Vases for table-decoration were particularly well done, the arrangement of the choice flowers employed being generally light and tasteful. Mr. E. S. Cole, Sneyd Park, Bristol, was again a good first, and was followed by Messrs. E. T. Hill, Westbury-on-Trym, and M. Hookings, Clifton. Mr. W. C. Drummond was first for both hand bouquet and memorial wreath; Messrs. E. S. Cole, M. Hookings, and J. Matthews also exhibiting successfully in these classes.

Fruit, especially choice kinds, was shown in great quantities, and the quality, considering the insignificance of many of the prizes, was much better than might have been expected. With a collection of ten dishes Mr. A. Miller, gardener to W. H. Long, Esq., Rood Ashton, Trowbridge, took the lead, having fine Foster's Seedling and good Black Hamburg Grapes, Barrington Peaches, Moor Park Apricots, Pitmaston Orange Nectarines, a Melon, Plums, &c. Mr. W. Rye, gardener to James Derham, Esq., Sneyd Park, Bristol, was a good second, his collection including very fine Ford's Seedling Peaches, Hero of Lockinge Melon, Morello Cherries, Red Astrachan Apples, Hamburg and Muscat Grapes. Mr. T. Smith was third and G. Garraway, Bath, highly commended. Mr. Miller was awarded a first prize for a fairly good Queen Pine Apple. There were several classes for Grapes, and the competition was good in every case. Messrs. A. Young (gardener to B. Thomas Esq., Clifton), George Hodges, Bath, H. Clack, J. W. Shelton (gardener to W. K. Wait, Esq., Bristol), F. Smith, Salisbury, A. Miller, were all successful. Peaches, Nectarines, Apricots, Cherries, Plums, Apples, and Pears were all shown extensively. Of vegetables there were immense quantities shown, and the quality generally was surprisingly good. The best collections were staged by Messrs. T. Evry, G. Garraway, and A. Miller.

FROME.

THE second attempt at holding a summer show at Frome was a decided success, and there is no reason why the Society should not have first-class exhibitions. Following closely on the Trowbridge Show a considerable number of exhibits came from the latter place. However, there was no mistake about the quantities brought together or the great advance made in the number of entries, and the numerous visitors appeared to be well satisfied with the display. There were no classes provided for trained plants, the principal prizes being offered for groups. Mr. E. Wilcox, gardener to Mrs. Simkins, Frome, was first, his neatly arranged group comprising a great variety of serviceable plants; and the same remark applies to the second prize group, arranged by Mr. B. Hopkins, gardener to John Baily, Esq., Frome. Mr. G. Tucker, gardener to Major W. P. Clark, Trowbridge, competed in this class with a number of trained specimens, but these did not find favour with the Judges, and were commended only. The latter exhibitor was a good first with a collection of Ferns, and was followed by Mr. Wilcox. Mr. Edwards, gardener to A. Haley, Esq., Frome, was first for *Fuchsias*, the second prize going to Mr. G. Taylor, gardener to A. R. Baily, Esq., Frome. Mr. Wilcox was first for *Coleus*, and Mr. G. Taylor second, both staging creditably. *Begonias* were well shown by Messrs. A. A. Walters, Bath, and E. Wilcox; variegated Pelargoniums by B. Hopkins and E. Brown, Chapmanslade; *Gloxinias* by A. A. Walters; flowering Zonal Pelargoniums by G. Tucker and E. Wilcox; and *Petunias* by E. Wilcox, who received the prizes.

With cut Roses, Messrs. G. Cooling & Son, Bath, were easily first, Mr. G. Garraway, Bath, being a good second. Mr. G. Taylor was a good first with twelve bunches of choice cut flowers, and Mr. Wilcox second. Several good wreaths were shown, but Mr. M. Coombe, foreman, Marston Gardens, was easily first, and he also displayed great taste in the arrangement of his first-prize eperguez. Mr. Garraway was first for hand bouquets, and Mr. M. Hookings, Clifton, was second in these classes.

Fruit was shown in great quantities, and in the competing collections of both fruit and vegetables the Bath professionals had extra large piles of each sort. Mr. T. Smith, Bath, was first for a collection of six dishes of fruit, and Mr. G. Garraway second. Mr. G. Taylor was first with three bunches of Black Hamburg Grapes, these being fairly well shown, and Mr. Garraway was second. The best Melon was staged by Mr. W. Thomas, gardener to J. F. F. Horner, Esq., Mells Park, and Mr. S. Andrews, gardener to A. G. Hayman, Esq., Frome, Hapsford, Frome, was second, both showing fruit of good quality. Messrs. G. Cooling & Son had the best dish of dessert Apples, a very handsome dish of Beauty of Bath, and in the class for culinary sorts Mr. J. Cray, Frome, was first with a fine dish of Lord Suffield.

Vegetables were shown in large quantities, both the gardeners' and cottagers' productions being most praiseworthy. In the open class Mr. Garraway and Mr. T. Ebrey, Bathaston, were equal firsts with collections, and Mr. C. Chedzey, Crocombe, third. The best brace of Cucumbers was staged by Mr. Cray, who had a fine brace of Carter's Model, and Mr. Hopkins was first in the class for Tomatoes with a fine dish of Sutton's Perfection. Col-

lections of salads were well shown by Mr. Garraway and W. Dredge, gardener to P. W. Cruttwell, Esq.

Miss Ormerod offered valuable prizes for the best collection of specimens of good plants injured by insects, with a short written account of the methods of remedy or prevention adopted. Mr. H. Haley, Frome, was again the only competitor, and received the first prize for a fairly good collection.

WALKLEY AMATEUR SOCIETY.

THE fourth annual Exhibition of this Society was held in the National School Rooms, Walkley, Sheffield, on Monday the 24th, and considered as a whole it was undoubtedly the most extensive and best display the Society has yet achieved. The members, considering that they are all without exception amateur growers, and in no single case employing a professional gardener, with the additional drawback that themselves are all nearly engaged in business away from their houses and their gardens during the greater part of the day, having only the early morning and evening at their disposal for gardening, contributed to the Show a great many truly surprising examples of first-class plant cultivation, amongst which must be mentioned as occupying first place the splendid groups of Gloxinias and exotic Ferns from Mr. Thos. B. Hague, the President of the Society. The Gloxinias, numbering eighteen, very large and vigorous plants, carrying from twenty to thirty very fine blooms each, were tastefully arranged as a group, intermixed with small, fresh, and healthy plants of *Adiantum cuneatum*, which formed a charming groundwork to their large dark foliage and bright flowers. Mr. Hague also exhibited a beautiful specimen of *Asparagus plumosus nanus*, nearly 4 feet in diameter. Amongst other exhibits worthy of special mention as shown by the amateur members, were Coleuses from Mr. Hague and Mr. Stocks, Begonias from the last two named and Mr. Barnes; pot Roses and British Ferns from several exhibitors. Cut flowers were numerous; especially so were German Stocks, of which we have not met with so large and excellent a display at any of the larger and more pretentious exhibitions we have this year visited.

Groups of plants, not for competition, were exhibited by the following honorary members of the Society:—Mr. W. K. Woodcock, gardener to Mrs. Mark Firth, Oakbrook, Sheffield; Mr. E. Holland, gardener to Duncan Gilmour, Esq., jun., Sandygate; Mr. Simpson, florist, Crookes; and Mr. Hartley, Birkendale. Mr. Holland's exhibition consisted of a number of very fine and fresh *Lilium auratum* and vars of *lancifolium album* and *rubrum*, having upwards of eighty fresh blooms, each expanded. He also exhibited a box of twenty-four cut blooms of *L. auratum*, amongst which were some fine varieties, and a large box of splendid blooms of cut Roses.

Mr. Simpson's group was charmingly bright and fresh, forming a very attractive feature at the entrance to the rooms; it was arranged as a large crescent-shaped bay, the centre of which was composed of Ferns, very clean, bright, and fresh, and the two wings of brightly coloured *Pelargoniums*. Amongst the best and most attractive of the Ferns in this group were *Adiantum venustum*, *glaucophyllum*, *gracillimum*, *Capillus-Veneris magnifica*, *Pteris scaberula*, *Cheilanthes elegans* (very fine), *Davallia Novae Zealandii*. *Pelargoniums* comprised some of the most newest and best amongst Zonals, single and double, amongst which we especially noted as very fine in doubles, E. V. Raspail, General Farr, and Paul De St. Victor. Included in the same group were a number of small plants in 48-sized pots of a charming new Fuchsia, double white corolla, large flower and very free, with excellent bushy habit of growth, named *Madame Jules Chrétien*, a variety worthy of note by all Fuchsia growers.

Mr. Hartley's group contained a number of fine varieties of *Amaryllis*, some pretty table plants, with a fine specimen of *Asparagus tenuifolius*. The group exhibited by Mr. Woodcock was an extensive one, occupying the whole of one end of the room, and consisting of choice flowering and foliage plants in great variety, amongst which were noticeable a number of plants in 48-sized pots, each about 15 inches high, bushy, and covered with bloom of the charming little stove annual, *Torenia Fournierii*. Grown freely in an intermediate or cool stove temperature until the plants come into flower are charming for conservatories in late summer, the rich and pleasing colours, with the profusion of flowers, rendering them attractive to all. A notable feature of this group was the mode of arrangement, the plants being so grouped that each individual stood out clearly and distinctly, the effect much exceeding that of the packing method of grouping so often adopted, as if to hide the defects of the plants, and which is certainly not conducive to high-class culture. The groundwork of Mr. Woodcock's group consisted principally of *Adiantums* and *Selaginellas*, amongst which the flowering foliage plants were so arranged so that each could be seen in its entirety.

The principal exhibitors for competition were Messrs. T. B. Hague, G. S. Stocks, J. Marson, F. Barnes, W. G. Cuckson, W. F. Singleton, A. Hill, A. Naylor, F. Revitt, Mallinson, H. S. Malton, H. T. Morton, J. Shipman, and H. Marshall.

HANDSWORTH FLORAL AND HORTICULTURAL SOCIETY.

AUGUST 26TH.

THE twenty-second annual Exhibition of the above Society was held on the date named. The weather was favourable, and this, together with the attractions offered (one of the principal of which being that Messrs. Fisher, Son & Sibray annually on this occasion throw open to the general public the whole of their extensive nurseries and glass houses), sufficed to bring to Handsworth immense numbers of people, principally from Sheffield, both by road and rail, the road during the afternoon reminding one forcibly of the road to Epsom on a Derby Day, so great was the crowd. The balance to the credit of the Society at its bankers, which was last year much enlarged, will we imagine be this year even more so, owing to the immense number who passed through the turnstiles from four o'clock until half-past five.

The Exhibition filled three large marquees, the principal one being an immense circular tent, in which the large groups occupying a space of 400 square feet each and open to all England were arranged. In this class there were four competitors, and an equally favourable position was secured for each by enclosing a circular space of 1600 feet around the central pole, and dividing this space into four equal portions by cords stretched at right angles across this space equidistant apart. The first prize, £20, was

well won by Mr. S. Thacker, Minerva House, Nottingham, with a very chaste and remarkable arrangement, differing most materially from the stereotyped mode of grouping with flowering and foliage plants and Maiden-hair Ferns. The whole of his floor space was formed into a series of mounds, hills, and banks by rough wooden platforms and supports, the intervening spaces forming miniature nooks and dells, the whole of which, with the wooden arrangements forming the hills were closely surfaced over with freshly gathered dark moss, similar to that which is used by exhibitors of Roses for surfacing their show boxes. Out of this moss surfacing sprang all the plants used, the pots being entirely hidden thereby. Towards the back of the group and overhead towered some lofty Palms, and underneath these as well as around the front was a great variety of flowering and foliage plants, so arranged that each plant stood out distinctly from those surrounding it, and maintained its own individuality, being well thrown up by the moss groundwork. Around the front edge such choice and small plants as *Anacochili* and *Nertera depressa* full of berries, between which were inserted small branches of dried ornamental grasses. The general effect produced was remarkably effective, added to which the arrangement possessed the merits of novelty, originality, and correct taste. Great difficulty was experienced in the evening in getting sufficiently near to see it satisfactorily owing to the crowd all the time gathered around it. Most excellent groups were arranged in the usual way, and were shown by Messrs. Hiram Shaw, nurseryman, Richmond, and B. Crossland.

Leaving the groups, the next most meritorious feature in the Exhibition was the collection of fruit (eight varieties), which were shown in the same tent on tables around the sides. The competition in this class was very keen, and some truly grand fruit was staged. Mr. E. Gillman, gardener to the Earl of Shrewsbury, Ingestre Hall, Stafford; Mr. T. Edward, gardener to the Duke of St. Albans, Bestwood Lodge, Notts; and Mr. G. Ward, gardener to T. Oakes, Esq., Riddings House, Alfreton, were first, second, and third respectively. Mr. Gillman's first-prize collection was superb throughout, and consisted of black and white Grapes, a Pine, Peaches and Nectarines, a Melon, Figs and Apricots. Such Barrington Peaches for size and colour as those in this collection have rarely been excelled. Some wonderfully fine bunches of Muscat Hamburg Grapes were exhibited by Mr. G. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle.

In the open class some magnificent Roses and Dahlias were shown, the former by Mr. R. Proctor, Chesterfield, and Mr. H. Frettingham, Beeston, Notts. A great falling-off was noticeable in quantity and quality of the exhibits in both the gentlemen's gardeners (local) and amateurs' tents, owing mainly to the prizes hitherto given in these sections having this year been greatly reduced in order to increase those in the open class for the large groups, and for the collections of fruit.

As before stated, the nurseries of Messrs. Fisher, Son & Sibray proved a great source of attraction during the afternoon, and were in most beautiful order throughout. Several large span-roofed houses filled with all the newer varieties of Zonal *Pelargoniums* and Tuberous *Begonias*, full of bloom, were especially gay, as also was another house, the roof of which was almost covered by a very large plant of their celebrated free-flowering variety of *Stephanotis floribunda*. The plant was quite covered with strong trusses of its snowy blooms, and excited the admiration of all who saw it. In the Orchid houses a goodly number of species and varieties were blooming; but one that especially attracted my attention was *Miltonia virginalis*, a most charming form, not often seen. The whole flower, which is equal in size and stoutness to the best forms of *M. spectabilis*, is of the purest waxy white, with the exception of a little carmine markings in the throat.

SANDY AND DISTRICT HORTICULTURAL SOCIETY.

THE annual Show at Sandy has now become so popular and permanent an institution for the counties of Beds, Cambs, Hunts, and North Herts, that nothing but a very hostile season and piteous weather indeed could prevent its material success. The display on Friday last was to some extent contracted in quantity and depreciated in quality by the long-continued drought, and the currently expected rain which usually falls on the day preceding the Show, and which on this occasion, true to expectations, thoroughly saturated the sward in the pretty park of Sandy Place, than which a more suitable spot for an exhibition could hardly be found, but as the soil is porous and quickly absorbs moisture, little disadvantage accrued, although it was sufficiently warning in its character to influence the attendance of distant visitors.

The horticultural show was, however, quite equal to the average of its predecessors, the competition in many cases being severe. The Poultry Show, which is always an important adjunct of these gatherings, was on this occasion an increased and unqualified success, and on the morning of the Show, the clouds having rolled by; the hopes of the Committee were sufficiently verified.

As might be expected, the chief falling off in the horticultural department in this sandy and chalky district was in the vegetable department which showed a marked deficiency in quality to those at the great Shrewsbury Show the previous week, the Potatoes especially lacking that combination of size and smoothness which is conventionally required of a show Potato, but which the appetite of the consumer does not always appreciate unless accompanied by a digestible carcase; and although a good coat may not always be characteristic of its wearer, a quarter of an inch of soil attached to the skin of a Potato neither improves the appearance nor the quality of the vegetable, nor adds to the neatness of an exhibition table. It does, however, frequently conceal blemishes and defects from the scrutinising eyes of the judges. Some specimens in the market gardeners' tent at Sandy set up in this rough-and-ready mode greatly outraged the required neatness of the display, and threw uncertainty on the decision of the Judges of this useful vegetable. Fruit was an average display, the collections, especially those from Warden and Houghton, being very fine.

Plants were good, and but for a railway breakdown, which shut out one unfortunate exhibitor, would have made a grand display; as it was, the effect in the plant tent was spoiled by an important position being filled with plants of much smaller proportions than the collections adjacent. The cut flower department was well furnished, and although the queen of flowers had for her champions the redoubtable growers Messrs. G. Paul and Son, House, Prince, and Burrell in the dealers' class, it was difficult to

select a single good average show Rose from all their stands. Perhaps the best "set up" was that by Mr. E. B. Lindsell of Bearton, Hitchin, in the amateurs' class. Dahlias, although not numerous, were represented by unusually fine stands from Mr. Petfield, gardener to G. Thornhill, Esq., Diddington, Hunts, who completely distanced the great Cheshunt and other growers, and should Mr. Petfield show his colours at the National this week it is not improbable that he may be in the van. Only one competitor put in an appearance in the open class for twenty-four *Gladiolus*—Messrs. Burrell and Co., of How House Nurseries, Cambridge—but their stand would have been a match for the famous Scotch growers from Gourich, shown last year at South Kensington. Asters, although better than last year, were not fully represented in colour. Zinnias not nearly so fine, but Marigolds, especially African, were, as usual, very well shown here.

The following were amongst the chief exhibits and awards:—

PLANTS.—For ten stove and greenhouse plants in flower, distinct, open to all, Mr. Jas. Cypher, Exotic Nurseries, Cheltenham, was first with a good selection from the many fine plants he has been able to produce this season. He had a grand specimen of *Phenocoma prolifera* Barnesii, 5 feet in diameter, and a *Rhododendron* Duchess of Edinburgh, bright scarlet in colour. Mr. W. Rabbitt, gardener to General Pearson, C.B., The Hazells, Sandy, an able local exhibitor, came in a good second, one of his most effective specimens being *Impatiens Sultani*. Mr. F. Mould of The Nurseries, Pewsey, Wilts, who was but little in rear, was placed third. For six stove and greenhouse plants in bloom, distinct, open to all except nurserymen, Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynesbury, Hunts, was first with an excellent and well grown lot in fine flower. *Dipladenia insignis*, *Bougainvillea glabra* being conspicuous. For six foliage plants in the same division, Mr. G. Claydon, gardener to A. H. Arkell, Esq., Woodbury Hall, was first, having *Curculigo recurvata* variegata, *Dieffenbachia Bausei*, and *Caladium Bellemeyi* in fine condition. The first awards for six stove and greenhouse and for four British Ferns fell deservedly to Mr. T. Tillbrook, gardener to Bateman Brown, Esq., Houghton, Hunts. For six *Coleus* Mr. Rabbitt was first, his most taking plant being Lord Chas. Beresford. Mr. Rabbitt was also first for twelve well-flowered Zonal Pelargoniums in the open class. In the amateurs' class Mr. F. Cinder of Brooke House, Biggleswade, gained first place with a creditable collection of eight plants.

CUT FLOWERS.

In the open class Mr. J. House of Eastgate Nurseries, Peterborough, was first for forty-eight blooms, not less than twenty-four varieties, with bright, but otherwise seasonable flowers; Marie Van Houtte, Alfred Colomb, and Exposition de Brie being flowers approximating most to the requisite standard. Messrs. Paul & Son, the Old Nurseries, Cheshunt, were second, having Marshal Wilder and Pride of Reigate, both giving promise of being good, new, as well useful autumn flowers. Mr. G. Prince of Oxford was not a far distant third. In the open class, dealers excluded, Mr. E. B. Lindsell, Hitchin, was deservedly to the front, the Rev. W. H. Gall, Hitchin, following second. The splendid first prize stand of twenty-four *Gladiolus* from Messrs. Burrell & Co., which was one of the sights of the Show, was made up of grand spikes with large and beautifully coloured blooms of the following varieties—*L'Africaine*, Baroness Burdett Coutts, a telling rose lake; Victor Jacqueminot, Leda, Mabel, Horace Vernet, *L'Unique*, violet; Hesperide, Colbert, Addison, La Perle, Carnation, Le Phare, Céleminé, Leandre, Jupiter, Condé, Amalthée, Rosita, Rossina, Madame Desportes, Archduchess Marie Christine, A. Brogniart, and Lapepède. For six *Gladiolus*, amateurs, Mr. P. Mayer was first, and Mr. Apthorpe, Cambridge, second. In the open class for twenty-four Show Dahlias, Mr. G. Petfield was *facile princeps* with magnificent blooms both in size and quality, the following being especially striking—John Henshaw, Wm. Rawlings, Mrs. Gladstone, white; Prince Bismarck, Jas. Veitch, Herbert Turner, pure white; Imperial, Mrs. Harris, and Goldfinder. Messrs. Paul & Son, who were second, had good but smaller blooms. For twelve Show Dahlias Mr. Petfield was again first, Mr. W. H. Apthorpe second; and for six Show Dahlias, in the amateurs' class, Mr. R. Clarke, Cambridge, was first. The principal prizetakers in Asters were Mr. Petfield, Mr. Tillbrook, and Mr. G. Taylor, Eynesbury; Mr. P. Meyer coming first with fine African Marigolds, and Mr. A. L. Clarke for Zinnias. Messrs. Burrell & Co. had a fine stand of cut herbaceous flowers; and from Mr. E. Edwards of Leighton Buzzard came two most attractive stands of double and single hybrid Begonias, not for competition. Miss H. L. Aslett of Woodbury Hall decorated a table very tastefully, for which she took the only honour, Mr. W. Rabbitt having in the same tent first prize for a very artistic model garden, the leading feature being a well proportioned scroll carpet of dark *Coleus* edged with blue *Lobelia*, the toning of the interstices with flatter colours being very effective.

FRUIT AND VEGETABLES.

For a basket or tray of fruit, eight distinct kinds (Pines excluded), Mr. Allis, gardener to Major Shuttleworth, Old Warden, Beds, received leading honours with an excellent stand containing Black Hamburg and Buckland Sweetwater Grapes in beautiful colour and finish; also Melon, Peaches, Nectarines, Apricots, Figs, and Cherries correspondingly good. Mr. Tillbrook's collection, which came a very close second, contained fine Madresfield Court and Muscat of Alexandria Grapes—the latter, however, not quite finished. Mr. White, gardener to Captain Stanley, Longstone Hall, Cambs, was here also a good third. Grapes were mostly good, but not equal to some hitherto shown at Sandy, the principal prizetakers being Mr. Allis, Mr. Tillbrook, and Mr. W. H. Murfin, Staughton, Hunts. By far the best Melon—an unnamed scarlet-flesh variety—came from Mr. F. Conder. Peaches, Nectarines, Plums, Pears, and Apples were shown in considerable quantity, but call for no comment. For a basket of twelve varieties of vegetables, Mr. C. Ellis, gardener to Mrs. Orr, Pemberley, Bedford, was first, having Sutton's Reading Perfection Tomatoes (very fine), Evolution Peas, Cauliflowers, Girtford Giant Runner Beans, and International Potatoes, all conspicuously good. Mr. G. Vines, gardener to H. Thornton, Esq., Kempton Grange, Bedford, securing second honours with an almost equally fine collection. For six varieties in the amateurs' division, A. G. Munro, Esq., Kempston, was first with a very attractive tray. The first prize for six varieties of Potatoes went to Mr. P. Meyer, the sorts being Schoolmaster, Prime Minister, Chancellor, Reading Russet, Vicar of Laleham, and Mr. Breese. The leading prize for twelve white kidney Potatoes was awarded

for a dish of Recorder, which is said to be a promising useful Potato, Beauty of Hebron coming in as the best coloured kidney, Schoolmaster as the best round white, and Vicar of Laleham as the best round coloured. In the market gardeners' division, Mr. R. M. Simpson, of the Three Counties Asylum, Arlesey, Beds, was first, having good samples of white Beauty of Hebron, Chancellor, Snowdrop, Sutton's King, Beauty of Kent and Adirondack. Onions, notwithstanding the drought, were in all classes better shown than many anticipated. Tomatoes were well represented, the leading prizes going to large samples from Mr. White and Mr. Apthorpe; but the dish of Reading Perfection, which seems to be a high quality fruit, was most admired for colour and beauty. Mr. Laxton, of Bedford and Girtford, showed, not for competition, fine specimens of his Sandy Prize White Spanish Onion, Girtford Giant Beans, and white Beauty of Hebron Potatoes, cooked and uncooked. The Judges thought so highly of this variety that a special first-class certificate was awarded to it, the flesh of the cooked tubers having a snow white appearance and the quality very good. It is also claimed for the Potato that it is not only early and a great producer, but cooks well, both when fresh lifted and quite late in the following spring.

Some irregularities again occurred at the close of the Show, several exhibitors being unable to secure their productions, and it is to be hoped that in future the Committee will exercise rigid discipline at clearing time, as nothing causes more mortification to an exhibitor than the loss of his cherished productions, and a continuation of such undetected pilfering must ultimately tend to injure the Society and to counteract the well-intended efforts of the Committee.

THE DUNFERMLINE AND WEST OF FIFE HORTICULTURAL SOCIETY.

THE fifth annual Exhibition of this flourishing Society was held on Friday and Saturday, the 28th and 29th August, in most favourable weather. While the grounds are in every way suited for such a gathering, it seemed to be generally felt that the change from the situation from Pittencrieff Glen of former years had sacrificed many of the external attractions which aided in making the annual gatherings of the Society so interesting and enjoyable to the ordinary visitors. Of the Show as a whole, it may be said to be the best which the Society has yet held, and that it reflected great credit upon the exhibitors and members of Committee, evidencing, as it did, great cultural skill and taste in arrangement.

Most important of the competitions were the tables of stove or greenhouse plants arranged for effect, Mr. Jas. Ferguson, Brucefield, securing first place with a very fair lot tastefully arranged; the second place being awarded to Mr. A. White, gardener to Dr. Dow, New Row, for a table, which but for a paucity of plants in flower, might well have been placed first, W. Cruden, gardener to J. Huut, Esq., taking third prize. For six stove or greenhouse plants, W. Cruden was first, Dr. Robt. Speirs, St. Leonards, being a close second.

Fruit in the gardeners' section was a notable feature of the Show, making an excellent display both as regards the quantity and the quality of the exhibits. Mr. H. McDermont, Alva, staging grand examples in his first-prize collection of eight sorts, as did also Mr. D. Howie, Duninmarle, in four bunches Grapes, four sorts; Messrs. Lumley, Broom Hall; Ovens, St. Margaret's; Cruden, Pittencrieff; Garret, Lassodie House; and D. Campbell, Keavil, being the other principal prizetakers for fruit.

Vegetables and cut flowers were, as usual at this Society's Show, a numerous and excellent display, affording evidence of the great attention paid to their culture in this district, amateurs vying with the gardeners in the excellency of their exhibits. Among the extra exhibits was a table of stove and greenhouse plants from the garden of R. Donald, Esq., Provost of Dunfermline, and the respected chairman of the Society, which was greatly admired by the numerous visitors, and a collection of Carnation blooms from Mr. J. Paterson, gardener, Lorrie House, among which a seedling of a delicate shade of pink, named Mrs. Erskine Wemyss, commended itself so much to the Judges as to receive the award of a certificate of merit.

The Committee had the enterprise to engage the celebrated band of the Royal Scots Greys, which discoursed an excellent programme of music to an appreciative and enthusiastic crowd of listeners upon both days.

SHERBORNE.

THE twenty-fourth annual Exhibition of this Society was held as usual in the picturesque grounds of Sherborne Castle under most favourable circumstances. Stove and greenhouse plants were well represented, Ferns and Mosses abundant and fine, and fruit much better than usual. Vegetables were remarkably good.

For twelve fine-foliaged plants Mr. T. Wilkins, gardener to T. M. Guest, Esq., Inwood, was a good first, having in his group extra fine plants of *Croton undulatus*, *Pandanus Veitchii*, and *Anthurium Warocqueanum*; and Mr. W. Appleby, gardener to T. W. Bide, Esq., Yeovil, was placed second for a creditable lot of plants. Mr. Wilkins was first for a miscellaneous collection of plants in or out of bloom, showing several choice specimens, the second prize going to Mr. G. Runacles. For a group arranged for effect Mr. G. Anthony, gardener to T. Moore, Esq., Yeovil, was first with a fairly good selection, and the second prize was withheld. In the class for Ferns and Mosses Mr. J. Crump, gardener to W. Neal, Esq., was easily first, having in his collection grand specimens of *Microlepia hirta cristata*, *Adiantum farleyense*, and *Davallia Mooreana*. For Begonias, Mr. J. Bowles was first with medium-sized profusely flowered plants, and Mr. J. Copp was second. Fuchsias were scarcely so good as usual, and with these Mr. Harriman, gardener to G. Whitby, Esq., Yeovil, was first, and Mr. Appleby second.

The good-sized tent was wholly given up to the display of fruit and vegetables. There were six entries for the silver cup, value £5, offered by Mr. Wingfield, Digby, for eight dishes of fruit, and in each case there were many excellent dishes shown. Mr. Pulman, gardener to R. B. Sheridan, Esq., Frampton, was the winner, his collection including good stands of Buckland Sweetwater and Black Alicante Grapes, Hero of Lockinge Melon, Dymond Peaches, and Williams' Bon Chrétien Pears. Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Langport was a good second, several dishes in his really good collection, with the exception of Muscat of Alexandria Grapes, being somewhat wanting in colour. Mr. C. Crossman, gardener to

J. Brutton, Esq., Yeovil, was third; and Mr. C. Perkins, gardener to C. H. Hambro, Esq., Milton Abbey, fourth. Several good stands of Black Hambrogh Grapes were shown, the first going to Mr. W. Iggulden, gardener to the Earl of Cork, Frome, for medium size, compact, and well-finished bunches; and Mr. Pulman was second. The last named was first with Muscat of Alexandria, and Mr. J. Lloyd second, both having well-finished examples. In the class for any other black variety, Mr. Crossman was first with Black Alicante in good condition, and Mr. Davidson, gardener to Lord Wolverton, Iwerne, was second with the same sort very well finished, only somewhat overthinned. Mr. Davidson was first in the corresponding class for white varieties, having Buckland Sweetwater large in bunch and berry and beautifully coloured, and Mr. Crossman was second with good examples of Waltham Cross. Mr. Pulman had the best Peaches, Dymond in good condition, and Mr. Iggulden was second with good Bellegarde. With Nectarines Mr. G. Daley was first with Pitmaston Orange, and Mr. Lloyd second with Lord Napier, both having good dishes. Melons were staged in good numbers, but the quality was very deficient in most of them. Mr. C. Chedzoy was first with Webb's Woodfield, a handsome variety with deep green melting flesh, and Mr. C. Perkins was second with Golden Ball. Mr. Brooks took a first prize for a good Smooth Cayenne Pine Apple, and Mr. Iggulden was second.

For a collection of twelve sorts of vegetables Mr. Wilkins was first, his collection including fine Autumn Giant Cauliflowers, Snowdrop Potatoes, and White Celery. Mr. G. H. Copp was a good second. With eight varieties Mr. A. Philpott, gardener to J. Parsons, Esq., Sherborne, was first, and Mr. J. A. Witherington second; both have generally good lots of vegetables. Mr. G. W. Copp was the principal prizewinner in the classes for single dishes. The amateurs also had a fine lot of fruit and vegetables.

Cut flowers were a grand display, consisting of Roses, Dahlias, Asters, and Gladioli, and were shown in fine condition. Mr. S. P. Budd of Bath, Messrs. Keynes & Williams of Salisbury, and Mr. J. Nation of Staplegrave, taking prizes in the respective classes for the two former; Mr. J. Harris and Mr. Iggulden for stands of cut flowers in bunches; and Mr. M. Coombe, Marston House Gardens, and Mrs. N. Harriman, Chard, for epergnes. In the class for ladies only Mrs. N. Harriman was first for bouquets.

Messrs. Lucomb & Pince's exhibits, not for competition, attracted great attention, notably their group of plants at the entrance of the flower tent, containing some well-grown specimens of *Dipladenia Brearleyana*, *Allamanda nobilis*, and also a group of choice Orchids and other interesting plants.

Mr. G. F. Stokes is the Secretary, and he, with the great assistance of Mr. W. G. Pragnell and other members of the Committee, arranged everything most satisfactorily.

READING SHOW.—AUGUST 27TH.

THE Forbury Gardens, Reading, together with the adjoining Abbey Ruins, is a most interesting resort both for the townsfolk and visitors. For many years also the garden has been very tastefully planted and kept, rendering it very bright and cheerful during the summer months, and this year its appearance is fully equal to the best of previous seasons, a fact which is highly creditable to the skill of Mr. G. Phippen, who has succeeded his father in the management. A better position could not be chosen for the Show than the Abbey Ruins, and it is pleasing to be able to record that in number and quality of exhibits, especially in the fruit and vegetable departments, the Show was all that could be desired.

The plants were not so numerous as usual, but there were sufficient to furnish the tent, the large groups and the Fuchsias adding considerably to the effect. Mr. Parham, gardener to H. J. Simonds, Esq., Caversham, was the chief prizetaker in all the leading classes, and showed some remarkably good plants. Mr. James of Lower Norwood, Mr. Sumner, gardener to J. H. Millard, Esq., and Mr. Mould secured the other chief prizes in these classes. Cut flowers were capably represented, but the collection of Dahlias from Messrs. J. Cheal & Sons, Crawley, Sussex, were exceedingly fine and well merited the numerous honours they gained.

Fruit was very well shown, and in this respect the Exhibition was one of the best held at Reading for some time. Grapes were especially good, the Black Hamburgs being finely coloured, well-formed bunches in nearly every instance, but the leading exhibitors in the class—Mr. Ashby, gardener to W. Fanning, Esq., Whitechurch; Mr. Turton, gardener to J. Hargreaves, Esq., Maiden Erleigh; and Mr. Cakebread, gardener to Sir P. Rose, Penn—contributed admirable examples of this useful Grape. In the any other black variety class, Mr. Ashby was again the premier exhibitor with magnificent bunches of Madresfield Court, that attracted the admiration of all who saw them. They were large, of fine symmetrical shape, and the berries were clothed with a dense handsome bloom. Muscat of Alexandria was not quite so satisfactory amongst the white Grapes, but in the other variety class Mr. Kneller, gardener to W. S. Portal, Esq., Malshanger Park, was awarded first honours for grand bunches and berries of Buckland Sweetwater, beautifully ripened. Peaches were handsome, mostly very large, but the prizes went to the best-coloured fruits of *Violette Hâtive*, *Grosse Mignonne*, and *Bellegarde*, from Messrs. Bowerman, Ashby, and Pound, who were the successful exhibitors amongst twenty-one who entered. There were fifteen dishes of Nectarines, Mr. Balchin, gardener to B. Simonds, Esq., Reading, leading with *Elruge*. Mr. Howe was second with Pine Apple, and Mr. Osborn, gardener to the Rev. H. Golding Palmer, Sonning, was third with Pitmaston Orange, all very fine fruits. The collections of fruit included some good dishes of Plums, Apricots, Peaches, and Nectarines, but the Grapes were weak in most cases. Mr. Howe, gardener to Sir R. Sutton, Bart., Benham Park, was an easy first, followed by Mr. Goodman, gardener to C. Hammersley, Esq., Bourne End, and Mr. King, Devizes Castle Gardens. Figs, Plums, Apricots, and Apples were all strongly shown, and several of the exhibitors already named took the leading honours.

Messrs. Sutton & Sons' prizes for a brace of Melons brought about twenty competitors, and the Judges had much difficulty in awarding the prizes. Ultimately, however, Mr. Howe was placed first with handsome fruits of *Hero of Lockinge*; Mr. Ross was second with General Gordon, a green-flesh seedling from *Semper Fidelis* and *Nowton Court*; Mr. Turton was third with *Hero of Lockinge*, and Mr. Howe fourth with *Benham Beauty*. Messrs. Carter & Co.'s prizes for Melon *Blenheim Orange* were won by Messrs. Lockie, Howe, and Balchin with good fruits.

Vegetables were of praiseworthy quality in all the classes, and the competition was very keen. Messrs. Sutton's prizes for six kinds of vegetables brought eighteen exhibitors, the prizes being secured by Mr. Richards, gardener to Earl Normanton, Somerley Park, Ringwood, Hants, Mr. Lye, Mr. Kneller, and several others whose names we did not obtain. Messrs. Webb's prizes for six kinds of vegetables brought fifteen competitors, Mr. Bowerman, gardener to C. A. Bovill, Esq., Hackwood Park, Mr. Elliott, Mr. Lye, and Mr. Lockie securing the prizes. Messrs. Sutton also provided a class for nine varieties of Potatoes, in which there were nine entries, Mr. Hott, gardener to Major Allfrey, Mr. Elliott, gardener to J. Hibbert, Esq., Braywick, Mr. Ross, and Mr. Lye being the successful exhibitors in that order.

EVOLUTION AND CHANCELLOR PEAS.

HAVING grown thirty-three different sorts of Peas in my garden this year, and seeing on page 154 Mr. T. Record gives an account of the late bearing qualities of that very good Pea *G. F. Wilson*, I wish to direct attention to *Evolution* as a late bearing variety. I sowed the seed on the 12th of February; the first gathering of Peas was made on the 20th of June, and the last dish I have gathered was on the 17th August, and the Peas are still bearing fine young pods, of which I enclose you one. *Evolution* is the longest bearing Pea that I have ever grown, I think its name ought to have been *Everlasting*.

I also see, page 158, that Messrs. Webb & Sons have sent you a sample of their new Pea *Chancellor*, and you are not able to give an account of its quality through the pods being too old, Messrs. Webb kindly sent me some of the *Chancellor* seed to grow, and I have had several cookings from the plants. They are very sweet and an excellent green colour when cooked. This variety is a robust grower and a large cropper, the pods coming nearly all in pairs.—HENRY MARRIOTT, *Prospect House, Skirbeck, Boston*.

[The specimen of *Evolution* received is remarkably fine, the growths vigorous, and as fresh as in June, bearing a half-grown pod, with others just set and flowers expanding.]

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 3.

SUCH a reproduction of a part of the City tenanted by the Londoners of bygone times as we see in the International Exhibition of Kensington, is rendered comparatively easy owing to the existence of some houses of old London and abundant drawings of others that have vanished; but what can produce for us a garden exactly representing one of those in which the wealthy citizens took delight when, after the Wars of the Roses, a taste for flowers began to be developed in England? If a Tudor philanthropist, for instance, could have secured to London in perpetuity the open space called Goodman's Fields as it was in the sixteenth century, how interesting it would have been to look upon, and what a boon to the inhabitants of Whitechapel. But Goodman's Fields, though the central portion is marked as an open space on maps of thirty years since, is now covered with streets of small dull tenements. There is nothing to remind us of Goodman, whose farm this was in the days of Stow, before the citizens rented the fields to turn them into garden plots, and both flowers and trees are scarce hereabouts. Only Prescott Street, formerly, so it is said, Peascod Street, is suggestive of some early cultivator of a vegetable chiefly grown in convent gardens during the Middle Ages until the Flemings brought Peas into general demand.

Very few are the by-passers who think of the Minories and its neighbourhood as once the demesne of the Nuns of St. Clare, nor has Royal Mint Street any of the aroma of the fragrant herb that at one time conferred upon it the name of Rosemary Lane. It does not appear, however, that Rosemary, so much esteemed by our ancestors, was grown there, but only vended along this lane with other herbs. Though now a locality of noisy trades and busy factories, varied with railway lines and depôts, it is possible to find about this part of eastern London open places, where plants and flowers, if seemingly straitened for air, do tolerably well under the circumstances of their life. In the unsavoury Royal Mint Street itself, originally Rosemary Lane, is a largish space, formerly an outlying churchyard of Aldgate, which belongs to the Metropolitan Board of Works, and at present lies barren and unpromising, yet which, by a moderate outlay of money and suitable management, might be made to yield both foliage and flowers. The honourable Board hoped, it seems, to utilise the ground by letting it upon building leases, but a recent Act prohibits, fortunately, any further erection of houses upon disused churchyards. Let us hope, then, that what is now verily a "a place of potsherds" may ere long become a pleasant garden, where some corner might be allotted suitably to the historic Rosemary.

Proceeding from the above into Cable Street, which continues the line of road, we reach the old churchyard of St. George's in the East, one affording a good example of what may be done within London limits to make an open space look always green and cheery. About nine years ago an arrangement was carried out by the local authorities, and the greater part of the burial ground, with that also of a Wesleyan chapel at its rear, were laid out as a flower garden for the public benefit. There is a caretaker beside the gardener and his assistants. The extent is probably two acres. The ground might be supposed to be larger, perhaps owing to the mode of arrangement, most of the shrubs being massed along the sides, so that the view is only interrupted by an occasional tree that has been left amongst the glass plots and flower beds. In a dry hot July we could scarcely expect to find trees and shrubs of London growth devoid of a tint of brown, but on our visit here we thought the foliage looked com-

paratively fresh for the time, and the grass was bright green through assiduous watering and clipping. Indeed, without constant care such plots will not flourish in London or in any large town, a fact which appears to be sometimes forgot by the managers of our metropolitan parks. Juveniles are rigorously excluded from the parterres in this garden, to tread or roll upon which would much delight them no doubt, and we suppose that, within the limited area, a piece of turf could not be set apart for their special benefit. Upon one of the grass plots it was curious to observe a thick growth of Milfoil or Yarrow, a wild plant which was not probably introduced with grass seeds or sods, but an old tenant of the place not easy to eradicate, yet, weed though we call it, one possessing an interesting folk-lore. Beds of flowers are formed here and there within the grassy spaces, and are thus effectually protected from the meddlesome fingers of adults and juveniles, but we own we cannot see much advantage to visitors from a floral display which has to be surveyed at a long range. And it would appear that the "touch-not" regulation is so strictly enforced in some of these public gardens as to make strollers fearful every moment lest they should incur a penalty. Possibly this is necessary, since the average English mind so closely connects the verbs "admire" and "handle." We were amused at the outspoken admiration of a corpulent dame who was evidently doing the gardens with a purpose to see all that there was to be seen. Her standard of excellence was Victoria Park, and she pronounced this renovated churchyard nearly as good as that, though it might not be as large.

The flower beds generally contained a fair average show of the plants we usually meet with—Pelargoniums, Pyrethrums, and Calceolarias being conspicuous. Fronting some of the beds where shrubs formed the background, Heliotropes, Lobelias, and Petunias, interspersed with Carnations, produced a pleasant effect, some annuals appearing amongst these, such as Mignonette. Our experience of this old London favourite has been that it comes up very well year by year if allowed to sow itself, otherwise there is some little difficulty in raising it from seed in the open air. Phloxes, as we commonly notice them in such London gardens as this, do not give one a favourable idea of the group; the reason is probably this, they are plants requiring peculiar treatment, which the gardeners have not time to bestow if they possess the knowledge. Several of the beds had an edging of the familiar red Daisy of our gardens behind an edging of evergreen, but the Daisies had gone out of bloom. It would have been strange had we missed the Elder, so seldom absent from a London array of shrubs, and a species somehow liked by cockneys; and the Poplar, as shrub or tree, is also popular. One not very aged Poplar, amongst a few others we noticed, presented a curious appearance owing to the numerous side shoots which almost hid the parent stem. Some space was allotted to Chrysanthemums, but it is small now; probably more will be given hereafter to a species offering so much variety, and which succeeds in London.

Water always draws the folk, especially in a dusty season like this, hence the rockery and pond had many visitors; the former was well planted, though we should have put in a greater number of semi-aquatic species and climbers. Speaking of climbers, why should not the winter-flowering Jasmine (*Jasminum nudiflorum*) be freely made use of to cover walls, railings, &c.?—It would not suffer, we believe, from the smoky influences. Nor do we see the Clematis introduced very often for the same purpose, or to festoon an arch across a path. The juveniles of St. George's might have got up a butterfly hunt had such been permitted, for numerous specimens of the garden white were disporting themselves on the flowers, and we ventured to remark to the gardener that to see these on the wing in the heart of London was a pleasing and interesting sight. But he was not sympathetic, and assured us that they were "a nuisance," crediting the insects, perhaps, with more mischief than can rightly be laid to their charge. They were, we presume, intending to deposit eggs upon the Tropæolums, but we have taken the caterpillars in the act of feeding on Pelargoniums or Geraniums.

Near the above are two smallish squares which are not open to the public, yet must be of some benefit to the neighbourhood, and their clustering trees are suggestive of rural shades. Wellclose Square was doubtless named from some ancient well, and Poplars still flourish there, some of them old trees that have been planted. A grove of closely set Elms occupy a part of the space, and part is grass, with a few scattered flowers, amongst which the Marigold is conspicuous. Prince's Square, within which is a Swedish Church, where lies interred the eccentric Swedenborg, has its Elms and Planes, fewer trees, but a better display of flowers of the hardy sort.—J. R. S. C.

KITCHEN GARDEN.

TURNIPS.—These are amongst the most useful of all winter vegetables. The majority of cooks call for them daily, and a constant supply should be maintained; indeed, the Turnip place in the scullery should never be allowed to be empty. Late crops should have every attention. Thin the plants out to 15 or 18 inches apart; hoe amongst them afterwards, and keep them free from weeds. Swedish Turnips are hardier and easier kept during very

severe weather than the white sorts, and many persons who are not bad judges prefer them. Where there are signs that the supply is likely to be short sow more seed at once. We find for very late sowing the very early sorts, such as Early Milan, turn in wonderfully quick, and seed of it sown now will produce nice sized bulbs by November, but they require to be used soon afterwards, as they are too tender to stand throughout the winter. They might, however, be stored. Summer Turnips have been very good this year; they swelled well and were clean and large. During the hot dry weather some of them became hot and stringy rather too soon, but sowing often and in small quantities usually obviates that difficulty. Sutton's Selected Snowball has been very good this summer.

AUTUMN-SOWN ONIONS.—These are a most important crop; without them we should frequently be without Onions in April, May, and June, and those who grow for exhibiting always find the autumn Onions valuable. In some instances they are sown before this time, and many are showing through the ground now; but very early-sown plants are not always the most profitable. The great failing amongst the class generally is their disposition to run to flower early in spring before any bulbs have been formed. We know of whole crops having been lost in this way, and early sowing is the main cause of it. Last year we had not one seeding plant in our garden, and we grow thousands. The ground can hardly be too well cultivated and manured for this crop, and the position should be open and sunny. Lime, soot, or salt should be dug or forked in rather freely to keep away the grub, as prevention is always much better than cure, and easier too. The white varieties, such as The Queen or White Italian, are the first to become ready for use in spring, and a quantity should be sown. We find those not transplanted are the first to bulb. Trebons is excellent to sow now for exhibition purposes, and Webb's Improved Banbury sown at this time becomes fine about midsummer.

CAULIFLOWERS.—A sowing of Veitch's Extra Early should be made on a south border to supply plants for keeping through the winter and planting out in spring. A little seed of Veitch's Autumn Giant may also be sown, as this will succeed the early variety, and prove very useful, especially for exhibition, during the early summer months. Sow thinly; when large enough some of the plants may be taken up and dibbled into frames or under handlights to be safe in severe weather, and some may be left in the seed bed as a chance lot to stand the winter. Sometimes we have found these do admirably, but it is all a question of weather.

VEGETABLE MARROWS AND RIDGE CUCUMBERS.—These are now in full bearing, and producing more fruit than can be used. This is very liable to happen about this time, and fruits left on the plants not unfrequently stop the young crop from swelling. This may not be observed now, but the mistake will be found out in October when there are no young fruits to cut. Late fruits are always valuable, and by closely cutting off all full grown fruits at this time the young ones will form freely and swell until frost cuts them off. Close cutting is the secret of late fruiting.

MUSHROOM BEDS.—The present is a very good time to form these for producing a crop during November and December. Collect one or more cartloads of horse droppings; pick the rough of the straw out from them, and put the mass in some airy place to dry for a week or so, then mix it with about half its quantity of loam soil, and form into a bed. The bed should be from 15 inches to 18 inches in depth, and any width from 3 feet to 6 feet. The material should be trodden down very firmly. At first there will be a good heat in the bed, but if the manure has been properly prepared this will not exceed 90°, or thereabouts, and the spawn may be inserted. The spawn cannot be too good, and it should be broken into pieces about the size of a pigeon's egg, placing them about 3 inches deep and 10 inches apart. The manure may then be levelled down and made quite firm, afterwards the surface of the bed should be covered over to the depth of 2 inches of friable soil. This should be made quite level and be beaten smooth. If the position of the bed be such that the surface is likely to become dry, a layer of hay should be spread over it. As to the best place to form a bed, it would be a difficult matter to find a wrong one, as they will succeed in all kinds of sheds and outhouses as well as in the best Mushroom house.

TRANSPLANTING.—If any of the autumn-sown Cabbage are large enough draw them up and dibble them in their bearing quarters. Finish transplanting Lettuce and Endive, and should there be any winter greens crowded together thin them out and plant in empty corners, which are now more plentiful than they were some time ago. Sow a patch of an early kind of Radish, and see that the supplies for autumn and winter are ample. The first of the winter Spinach may be sown, keeping the rows 18 inches apart, and allowing it good soil that the leaves may become large and succulent.

FRUIT FORCING.

VINES.—Those intended for early forcing in pots should now be divested of all laterals close down to the cane or main buds, and in the case of their being still under glass no time should be lost in removing them to the front of a south wall in the open garden, where they must be well secured against injury from winds; and to prevent the roots becoming too dry, or those against the sides of the pots from being injured, some some litter or fern may be placed loosely about the pots.

Early House.—The permanent planted early forced Vines should be encouraged to go to rest by removing all lateral growths, care being taken of the old leaves, as they will help to feed and perfect the bunch producing buds. It will be necessary to give an abundance of air, or the lights may be removed if the weather be fine; but with the roots in a satisfactory condition the check following the removal of the laterals is

generally satisfactory in producing the desired effect—maturation and rest.

House Cleared of Fruit.—Vines that have been cleared of Grapes will need a thorough washing with a syringe or engine to cleanse the foliage from dust and red spider, and the laterals kept well in hand, unless the Vines have been heavily taxed in carrying a heavy crop, when a moderate lateral growth will promote root-action and have a recuperative effect upon the Vines; but the principal foliage must not in any case be interfered with by crowding, it being essential that they have full exposure to light and air, as upon their continuance in health depends the perfecting of the fruit-bearing buds. A moderate amount of moisture in the border is absolutely necessary, but it will not be necessary to have them more than healthfully moist, but anything like dryness should not be allowed. If the Vines have not the wood as ripe as desirable, allow the temperature to rise to 80° or 85° by day, with early closing, and throw the house open by night. Houses of ripe Hamburgs, &c., will be better with some slight shade for a few hours on bright days, as, independently of the berries losing colour, the strain of a heavy crop taxes the energies of the Vines, and the shading lessening evaporation reduces that strain considerably.

Muscats and Winter-hanging Grapes.—These are or ought to be of a degree of ripeness admitting of a reduction of fire heat and a lower temperature through the night, which applies to houses that were helped forward with a little fire heat in the spring, but where this was neglected from parsimoniousness, trusting to sun heat, the Grapes will not be in a condition to keep well. The Muscats will not have a fine amber colour, nor the black kinds well coloured or ripened, and in their case the fires will have to be kept going, which, though necessary, is not favourable to the finish or keeping of the Grapes. Whatever fire heat is needed should be applied chiefly in the daytime, with a circulation of air constantly, but the Vines should be rested at night by turning off the heat, or so much of it as will allow of a decline to 65° or even 60° on cold nights.

Houses of Late Hamburgs.—The Grapes are colouring fast, the bright weather having forced them forward with greater rapidity than is desirable, especially where they have to be kept for use in December. When this is the case a good spread of foliage for the next month or six weeks will be of great service in delaying the ripening and preserving the colour of the fruit. As days decrease in length, and there is danger to be apprehended from damp, the steady reduction of the laterals and increased ventilation, with gentle fire heat, will be advantageous to the Grapes and the ripening of the wood. As the season advances the Grapes should be cut with wood and placed in bottles of water on a shelf or elevated position in a house in which the late thick-skinned kinds are hanging, such as Lady Downe's, which require some time to mature after they are apparently ripe; but to succeed with late Hamburgs it is necessary to cut off all the largest shoots, depending on the medium-sized bunches for the crop, and well thin these to prevent the berries from binding. The Vines being cleared of fruit the spur shoots can be cut back to five or six eyes, and fire heat can be applied until the wood is thoroughly ripe. Perhaps there is no Grape so much esteemed as Black Hamburg late in the season, and those that can command these with Muscat of Alexandria at the dessert at the winter's festive season rank as first-class Grapeists.

CUCUMBERS.—Plants recently planted out will require treatment in accordance with the time when they are expected to bear fruit. If to produce a supply of fruit as soon as possible early stopping will be needed, commencing at the second or third wire of the trellis, which will cause fruit-bearing shoots to emanate; but in a majority of cases the object is to secure fruit in time to succeed those grown in pits or frames, in which case the plants may be allowed to grow until they reach the fourth or fifth wire of the trellis before being stopped, and all the fruit removed as it shows, and from the axil of each leaf will proceed a shoot or lateral, which should be allowed to grow until they nearly meet before they are stopped. This concentrates the vital energies on the development of leaves and wood which, being solidified by judicious ventilation and exposure to light, the plants are qualified to produce continuously a good supply of fruit during the winter and early spring months. Water must be applied somewhat sparingly until the plants have become well established, when with plenty of roots permeating the soil they will need more liberal supplies; but avoid over-watering and over-moisture as the greatest of evils, leading to soft growth, as only plants with thick leathery leaves and firm short-jointed wood are likely to endure the strain on them at a later period. The temperature should be kept at 65° at night and 70° to 75° by day from fire heat, with a rise to 80° to 90° from sun heat.

PLANT HOUSES.

Chrysanthemums.—Plants grown for producing large flowers must be examined at intervals of a few days, for the flower buds have commenced forming. The bud being produced now is what is commonly called the crown bud, and if well-developed flowers are required this bud must be taken. If the bud is perfectly healthy in appearance, the growths, as soon as they can be seen, should be removed from around it with the point of a sharp knife. All growths below should be removed from the axils of the leaves, so that the whole strength of the plant can be concentrated into the central flower that is left. If the bud is unhealthy remove all but one shoot, which will extend to 6 or 9 inches in length, according to the variety, and will produce what is termed the terminal bud. Three of these shoots can be left if several flowers are required from the plant or the shoot. The terminal bud differs from the crown bud in having other buds nestling close around it instead of growths. As soon as the

terminal bud has formed, all the other flower buds should be removed. If from six to twelve large flowers on bush plants are preferred to a greater number of smaller ones, they should be disbudded as soon as the crown buds make their appearance. All the plants required for yielding useful cut blooms, or for all ordinary forms of decoration, should not be stopped or pinched, but be allowed to branch naturally, and hundreds of useful small sprays of bloom will be the result, and these will be found much more serviceable for cutting than those of a larger size. The plants intended to supply large blooms must have a top-dressing of rich material to keep the roots active, and supply stimulants liberally in a weak state every time water is needed. The last applies to plants grown for decoration and cutting. Plants that have exceeded the length of their stalks are very liable to be broken during windy weather. The stalks should be lengthened to prevent this, or one or two ties cut during wind so that they can sway to and fro, which will prevent them from snapping.

Roses in Pots.—If Hybrid Perpetuals established in pots have not been repotted it should be done without farther delay if they need it, or they will not have time to become sufficiently established before winter. If the pots are already large enough turn the plants out and carefully remove about one-third of the old soil, retaining as many roots as possible, repotting them in the same size in a compost of good fibry loam, one-seventh of manure, and a little coarse sand, according to the nature of the loam. To this may be added one 6-inch potful of bonemeal to a barrowful of the compost, and the same quantity of soot. Those that do not require repotting should be examined to see if the drainage is sufficiently clean to act the part for which it is provided. From these a good portion of the old surface soil must be removed and top-dressed with the same compost, only one-third instead of one-seventh of manure may be used. After potting and top-dressing, as the case may be, the pots should be plunged and the foliage syringed twice daily.

Tea Roses.—Those intended for early forcing should also be repotted if they need it, or top-dressed, the same compost being used with the addition of a little leaf mould: this and the manure may amount to about one-third. Treat them the same as the H.P.'s after potting. Plants in pots that have remained indoors up to the present time and do not need repotting should be top-dressed, re-tied, and stood outside until the end of next month, when they should be housed, and if liberally treated will break into growth and produce flowers until Christmas. Young stock rooted in spring for the same purpose should be transferred without delay into 7 or 8-inch pots, plenty of leaf mould being used in the compost to encourage a free and rapid growth when the days are dark and sunless. Grow these plants under glass and remove the flowers as they appear. It is a good plan to strike cuttings now of Gloire de Dijon, Maréchal Niel, and similar varieties for growing into strong plants another season for early forcing the following spring. Cuttings of the smaller-growing varieties may also be rooted now, for few plants are more useful for decoration than these are in 5 and 6-inch pots. Where plants are placed under glass and early flowers are required, the main object should be to bring growth to a standstill and thoroughly ripen the wood. Open the house wide day and night.

THE FLOWER GARDEN AND PLEASURE GROUND.

Propagating Bedding Pelargoniums.—The Zonal Pelargoniums have, considering the excessive dryness of the season, succeeded remarkably well, but at the same time cuttings will not be very abundant. If they are fewer in number they will be harder than usual, and therefore more certain to strike freely. No time should be lost in getting in as many cuttings as are required, in order that they may become well established before the dull winter months arrive. Select, where possible, without disfiguring the beds, the most prominent and best ripened cuttings, cutting to a firm joint and trimming off the lower leaves. Any light sandy soil will be good enough to keep the plants alive during the winter, as the less they grow the less likely are they to damp off during a trying winter. Road grit or fine ashes from the stovehole will answer quite as well as silver sand for mixing with the soil, and the boxes or pots may be drained with clinkers or coke. We prefer to dibble the more delicate bronze, silver, and golden-leaved varieties into well-drained pots, or say about four cuttings into a 4-inch pot, and six or more into a 6-inch pot, and they can then be stood on dry shelves to winter. The more robust may be dibbled thickly into boxes, and with ordinary care will survive most winters in cool houses or pits. If they must be wintered in frames, then large pots should be preferred to boxes, as the latter cannot well be kept dry enough to prevent the plants damping off. In cold or moist localities the cuttings ought at once to be protected with glass, as should the soil become saturated with rain many of the cuttings will perish. In no case should much water be given, all that is required being to prevent undue shrivelling.

Verbenas, Ageratums, and Heliotropes.—The principal portion of these are usually struck in the spring, and for affording abundance of healthy cuttings strong autumn-struck plants are preferable to old ones that may be potted from the ground. Short, soft, and flowerless shoots should be selected, and these, after being duly trimmed, may either be dibbled into fine sandy soil over a mild hotbed and covered with a frame or handlight, or they may be put into boxes, pans, or pots filled with fine and fairly good soil, and placed in a mild hotbed to strike. In either case they should be frequently sprinkled with water, and be kept close and shaded from bright sunshine till well rooted, when plenty of air should be given. Air must be given in small quantities on the first signs of the cuttings damping off, and any that are decaying should be removed at once.

Iresines, Coleus, and Alternantheras.—Young plants of these also are the best for stock purposes, and cuttings ought to be struck at once.

These have to be wintered on shelves in forcing houses or stoves, and for this reason 5-inch pots are found the most convenient size for them. The pots should be well drained and filled with a light and rather sandy mixture. About six soft cuttings may be placed in each, and these will require to be placed in a warm frame or propagating pit to strike. All three kinds lift readily, but will not do well afterwards unless housed before they are injured either by much cold rain or early frosts.

Succulents.—If the tops of *Mesembryanthemum cordifolium variegatum* are cut off, dibbled into well drained pans or pots of sandy soil, and placed under glass in the full sunshine, they will strike readily and afford a number of cuttings in the spring. Any other trailing or branching succulents, including several *Sempervivums*, may also be similarly treated. The popular *Kleinia repens* is best struck at the present time. Give the preference to short, sturdy tops, and after they are trimmed allow the cuts to dry and partially heal before they are put in. They may be dibbled in thickly in well-drained pans or boxes filled with light sandy soil, and be struck in a sunny dry frame or pit. Succulents require but little water at any time, and especially when as cuttings or during the winter.

Tuberous-rooted Begonias.—A more moist season best suits this valuable class of summer-bedding plants, but with mulchings and occasional waterings they have done well in spite of the long drought. If it is thought desirable to increase the stock of any of the varieties it is best done by cuttings, much after the manner of striking *Pelargoniums*. They will root more surely in the open ground than under glass, and a moist heat such as suits *Verbenas* would prove fatal to them. It is rather late to put in cuttings in the open ground, but they may be dibbled into pans, pots, or boxes of light sandy soil and placed in a cold frame to strike. Give sufficient water to prevent shrivelling, but avoid heavy saturations. Any flowering shoot may be made into a cutting, and this will not decay till a small bulb is formed at its base. These bulbs should be wintered in a frame or greenhouse, where they can be protected from frost and yet not become very dry.

Dwarf Lobelias.—Seedlings of these are now of good habit, and can be depended upon in most bedding arrangements, with the exception of carpeting designs. If the seed is sown on the surface of pans filled with light soil and faced over with sand, and stood in a cold frame, and kept shaded from bright sunshine, and uniformly moist, a great number of seedlings will be obtained, and which will usually prove superior to those raised in the spring.

THE BEE-KEEPER.

THE STEWARTON HIVE.

THE good accounts given of the Stewarton hive by those who, through a long course of years have given it a trial sufficient to test its full efficacy for gaining a large amount of super honey of good quality and readily saleable, have induced me to order from the Scotch carpenter of Stewarton hive renown specimens of this masterpiece of bee appliances. In doing so I am not in my own mind quite satisfied that the honey obtained from it will be better in quality or greater in quantity than the product of the hives I now have in use. There is also another and a weighty consideration, before producing honey in a super of the form generally in use on such hives as the Stewarton, which is the saleability of the super as a whole. Now, residing near Manchester, within an hour's journey, a good market is at hand for bee produce, but my experience in selling is quite averse to the production of honey in the comb in any form other than the ordinary 1 lb. sections. Large supers of glass, of wood and glass, or of any other combination, are saleable only at a very low price, leaving only the alternative of selling at the reduction or draining out the honey and selling in the form of run honey in small bottles, which find a sale at prices very little, if any, inferior to honey in the comb of the purest quality and in the neatest sections.

The question then resolves itself into this, Can I from a Stewarton take a quantity of honey sufficient to make up for the low price the supers sold as a whole produce when sections only are acceptable? or, if not, can I, taking into consideration the trouble, the expense of bottles and labels, get extracted honey sufficient to make up the difference, and, in addition, in extracting honey there is considerable waste, which would also have to be allowed for in making the calculation? Can, then, this be done, and a margin left to make the increased expenditure on the hive a remunerative outlay?

Time alone can prove, but it is a case in which the safest course to pursue is to introduce the hive but gradually, carefully noting the result, and after a fair trial either discard it or use it more freely, as the result shows a profit or a loss by its use. For sections a ten-standard frame hive answers very well, and the cost is but 10s., and if made at home 7s. will cover the expenditure.

These hives, albeit rather smaller than the new ones I purpose constructing, are now in use. Last year one only was in use, yielding me upwards of sixty 1 lb. sections; this year, from the same stock, sixty-three 1 lb. sections [with almost the certainty, if fine weather continues, of getting forty-two more], all finely sealed and finished, have been taken. Can a Stewarton beat this record? Next year it shall have a trial in my small apiary. A Stewarton and a bar hive of the make I now use shall be stocked with bees of weight proportioned to the relative sizes of the hives, and fed by syrup into good strong stocks early in September; this mode of trial being, to my mind, the easiest to put each hive on the same foundation and to found the basis of a good trial, the result of which will, if possible be given, so that a record may be formed of the achievements of a Stewarton and bar hive in friendly rivalry. If "A Lanarkshire Bee-keeper" finds any objectionable feature in this proposed trial, any proposition of his shall have my most careful consideration, and, if possible, adoption.

In conclusion, let me add that, as an admirer of Mr. Pettigrew, I do not venture to put into competition for super honey his large hives; but if weight of honey were the only consideration, one of his large skeps would be found well worthy of the place that has been assigned to them by clever managers. All my stocks but one are managed on the non-swarming system, and, as I hope to show when the time arrives, the system will compare favourably with the antagonistic system, even after deducting from the profit a sum sufficient to buy bees to strengthen the stocks and to maintain them in a high state of efficiency.—FELIX.

UNITING SWARMS.

I CAN get as many bees for the driving as I wish to have, as no one here preserves them when taking the honey. In order to try them I have made a hive 17 by 12 inches, with eleven bars, and as the largest hive I can get is 13 by 9½ inches, I would require to put two or three swarms into my hive. How am I to proceed to get them to unite? what breadth of foundation comb would be sufficient to give bees a start on the bars? should wooden hives be painted inside? and how should floor boards be ventilated? I only commenced bee-keeping last June, hence my want of information. Since that time I have consulted several old volumes of your Journal which I had beside me. A calendar by Mr. Pettigrew, 1884, gives a vast amount of information, but answers to the above questions would greatly oblige.—JAMES EDGAR.

[Hives 13 by 9½ inches are very small. It will take three or four swarms from such hives to make a good one and build out the combs satisfactorily. To unite these swarms, have a large hive or box, into which put the first swarm, and as the others are driven and full of honey invert the first hive and shake the others into it. When full of honey and put into confusion by the operation no fighting takes place. Wooden hives should not be painted inside. Ventilating floors.—Make an eke about 2 inches deep, but otherwise of the same dimensions as the hive, nail or tack the perforated zinc on one edge, and either have a sliding or hinged bottom on the other. The breadth of foundation to be used depends a great deal upon what sort of wax the foundation is made from. If genuine home-produced wax is used fill the frame to within half an inch of the bottom rail, and nearly touching the ends. By doing this there is a chance of getting the frames filled and capable of being handled with safety.]

A BEE ADVENTURE.

HAVING at the commencement of the season a larger number of hives than I generally attempt, I had not time to attend to them as I intended. I wished to cut out queen cells and have super honey only, or, what was the same thing, sections in the rear of the bars. Two of my stocks were straw skeps. These, I thought, would give me a couple of swarms each, and I might count on some young queens to take over the queendom at the fall. This was all very well in my head or on paper, but our little friends have a way of "ganging their ain way." I had no time to cut out queen cells, and so I put on supers, either sections or regular supers, and hoped. The skeps swarmed. These were hived, and the second swarms pepperminted and mixed with

the first. Meanwhile I had one bar-frame stock filling sections, another working well in a glass, and another working both above and at the rear. This latter I had bought in an Abbott's combination standard, and on examination found they had been allowed to follow their own will, and had built across the bars. I determined to leave these till the fall, and then hive these, but I put a Crystal Palace super overhead, and eight 2 lb. sections in the rear. They soon set to work, and so far as I can tell these are the only stocks that have not swarmed. I have taken one set of four 2 lb. sections from the rear, having another nearly complete, replacing with an empty, which I have not yet examined. They are sealing the front and rear combs of the Crystal Palace super, about 20 lbs., and this I lifted, and placed an empty one under, in which they are steadily working, so that their stock will probably yield over 40 lbs.

The stock working in a super of sections, after filling some 25 lbs., swarmed and ceased super work, though I have since taken two bars of honey. Meanwhile, a stock working well in a mahogany and glass super I was anxious to exhibit, swarmed and ceased work aloft. This was a great disappointment to me. When getting home on most days there was a swarm from one or other of the stocks, but there being no one at home to watch them, one or more got away; but the plan I adopted was to add them after supplying scented syrup to one of the other swarms, so that I obtained two that were very strong.

The plan I adopt, and I have found it the most successful, is this. I have a large bottle of syrup, thin; in this I put one of the aphid spray producers, with a flexible tube to the mouthpiece; then in the evening I smoke the stock, and taking bar by bar spray them well with the syrup, also any separated bees not on the bars; then, serving the swarm which has been hived in a skep and safely tied down in the same way, I throw them in at the back of the hive.

This plan has succeeded capitally, scarcely any quarrelling, and I was anticipating great things, but it does not do to weigh your honey before you have it, any more than to count your chickens before they are hatched. I placed the mahogany super on a stock made up of three swarms. The bees took possession, and my mind was easy, but after a little, though the super was hot, the bees were not, and the honey already in the super did not appear to increase. Then I felt convinced that this mixed swarm must have swarmed, for there were fewer bees at the mouth of the hive and fewer in the super; so, being very anxious to get this mahogany super filled, I removed it. But two bars were nearly finished. I placed this on another mixed swarm, and two or three more bars were filled up, but our season is over, and I failed as to exhibiting this super. Soon after I removed it from its second place—the mixed swarm—I felt convinced that there was something wrong. The bees crowded the entrance; true, the weather was hot, then they hung out. This increased greatly. They swarmed down one leg of the hive, then they formed a mass on the ground. At that time I was very busy, had scarcely a moment to look at them. However, just before bedtime the evening that I had noticed them in a hunch on the ground I took a light to them to see if those on the ground had gone up. No, there they were. Glancing at the entrance I saw that the bees seemed crowded all round it, and on placing the light down found the alighting board a mass of honey and drowned bees. The explanation was of course that some accident to the bars had occurred. The following day I opened the hive. The second, third, fourth, and fifth bars had all given way—whether one had succeeded in breaking down the others, or they had all given way with the heat, and the floor of the hive was a mass of honey and dead bees. I immediately got another hive, and the bars were taken out, bees brushed off, &c. Meanwhile the broken pieces of comb were piled on a dish, taken indoors, and placed on a counter. Near this dish was a small box of scales and weights. There they were left, the bees transferred to their clean hive, and hopes that the queen was all safe, &c. Three or four hours, the broken pieces were taken away to the extractor; then my assistant, accidentally going to the box of weights, lifted the lid, but as suddenly retreated, for a bee, of which he has a mortal horror, issued from the same. "Oh!" I said, "you need not be afraid, only a drone," and was just going to give the supposed gentleman a *coup de grâce*, when I recognised her majesty. How she got into the box of scales was a mystery. I caught her, and placing her on the feeding hole, she quickly vanished. Three days after I found eggs in the new comb, and the hive has been rapidly repairing damages since. Scarcely a dozen bees were taken in with the pieces of comb, and it is singular that amongst these should have been the most important. Still more singular that she should have got into the box which was close at hand, certainly, but how she got in and shut down the lid is a much stranger affair. But there she was ready to issue from it as soon as the lid was lifted, as I saw myself.

To those who think bees should take care of themselves I think the late winter must have been disastrous. The bees were often on the wing, hence consuming more of their stores. Then May here was bitterly cold, and very little honey to be found. So among the cottagers I have not been surprised to hear they were busy and strong in April and then died away, some of them having lost several. To those who have been able to devote plenty of time to their little workers I cannot but think the harvest has been fair, if not abundant. I think about my neighbourhood the latter.—Y. B. A. Z.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London.—*Descriptive Catalogue of Bulbs, Fruit Trees, &c.*

Edmund Philip Dixon, Yorkshire Seed Establishment, Hull.—*Catalogue of Bulbs, Spring-flowering Plants, Strawberries, &c.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Abnormal Leaf (Thos. Meredith).—We are glad to see the monstrosity, which differs somewhat from others of the same nature that occur in gardens. It appears to be a twin leaf, the force of the sap having divided the stalk and, as it were, split the blade, and its expansion having been thereby arrested a secondary purse-like leaf has pushed from the midrib. It is a very singular example of malformation.

Root-pruning (F. J.).—You had better not prune the trees till the crop is gathered, which you say will be in October. The remarks on root-pruning in September are, as you intimate, sound and clear, but they apply to fruitless trees of luxuriant growth. Yours, it appears, are not quite fruitless, yet are growing too freely, and you will not err by root-pruning in October, or immediately the fruit is gathered.

Top-dressing Chrysanthemums (Cambridge).—You cannot do better than top-dress your plants at once, which will assist in keeping the roots active and supplying the plants with the necessary food to enable them to develop their flower buds. It is surprising what assistance a top-dressing of rich material proves to the plants in their latter stages, after the roots inside the pots have taken full possession of the whole of the soil. A system of top-dressing is practised by the majority of those who grow large flowers for exhibition. You will find equal parts of good fibry loam and cow manure with a little soot, say a 6-inch potful to half a bushel of soil, an excellent top-dressing for your plants, and the roots will not be long before they take possession of it. Some first-rate cultivators top-dress their plants with cow manure only, but we prefer the compost advised above.

Ranunculuses from Seed (Amateur).—Keep the seeds you have saved in a dry cool place. Early in spring mix a compost of strong loam and leaf mould, and fill some boxes or seed pans, well drained, very nearly full; sift a portion of it and place a thin layer over the rough compost, and press it very gently down. Mix the seed with some fine soil, rubbing the seed and the soil well together till the seeds are separated from each other. Sow this mixture upon the soil in the boxes or shallow pans; press it down level, and with a fine sieve sift some of the compost evenly over it the thickness of a shilling; then with a watering pot, the nozzle of which has the finest holes, give a gentle watering. Place the seed pans under glass in a cold frame or pit, or in front of a low wall facing the east, and contrive a covering or shelter of some kind to protect them from heavy showers. Whenever the soil appears dry give water with the fine-rosed water pot, and in strong sunshine place a shade over them till the seedlings appear above ground and have attained a leaf or two to each plant. Search well about where the boxes or seed pans stand, and even lift them up and examine under them to see if any slugs or woodlice have crept there to hide themselves. Continue this attention till the leaves begin to decay and then cease watering, but keep the plants clear of weeds. When the leaves are all decayed and winter is approaching place the pans of seedlings in some very cool place where no rain can fall upon them, and keep them there till spring. About the middle of April bring them out and give them a good watering. Sift over the soil a thin layer of fresh compost, and repeat the care and attention with regard to watering, looking after insects, and keeping clear of weeds as in the previous season. This second year, when the leaves fall and the plants are at rest, the tubers will have attained some size. They should now be taken out of the soil, and the surest way to accomplish this without losing any roots is to sift the upper part of the soil through a fine sieve, fine enough to catch even the smallest roots. Store them away in a cool dry room, and in the spring plant them out.

Young Vines (An Amateur).—It is difficult for us to say why the berries of your Grapes are small from the information supplied to us. The size both of the bunches and berries depends in a very large measure upon the growth the Vines made last year, and also upon the condition of the wood, whether thoroughly ripened or not. It is impossible to expect Vines with unripened wood that possess neither strength nor vigour, whether young or old, to produce berries of a large size. Young Vines very frequently produce large-sized bunches, but the berries are often smaller than from vigorous Vines of a greater age. This is not always the case, for much can be done in swelling the berries to a large size by good cultivation, which under inferior treatment would only be small. The pruning would have nothing to do with the size of the berries. You cannot expect us to answer your other question about the soil, for you have not said one word whether you made special preparations for your Vines, or in what compost they are growing. If your letter had been less brief we might probably have given you a more useful answer.

Plan of Rose Garden (A Lady Gardener).—We have no design exactly adapted to the peculiar form for your lawn, and you can scarcely expect us

to prepare and engrave one at a cost equal to three years' subscription to the Journal, and which could be of service to no one but yourself. We have given you a list of Roses, and stated that the beds cannot be too plain in outline, and suggested that a series of circles and oblongs would be suitable. We now show a combination of beds of the nature indicated, and by adding more and arranging them in accordance with the shape of your lawn you may make an enjoyable Rose garden. The space between the beds should exceed three times their diameter, it being a great mistake to crowd too many Rose beds on a lawn and to have them of fanciful designs. If the ends of the beds 12 and 13 are scalloped, a round bed placed next, then another arched oblong, then a round, and so on, following the curve of your lawn, the series will look very well, and you will only have to place other beds in harmony between 8 and 10 and 11 and 9 to complete the arrangement. You can dispense or not with a bed in the centre, but if you have one it is worth consideration as to whether an oval would not be more suitable to the form of your lawn than the circular bed (1) in the plan. It does not follow that the beds 6 and 7 should be of the exact shape represented. Exercise your own taste in the matter. You will find it neces-

Fig. 37.

easy to examine the design from the side, as the figures indicate, to understand what we have said as to its extension and modification.

Vines Unhealthy (A. B.).—The specimens that were sent to us before clearly did not represent anything like the actual condition of the Vines, and we are sorry to have been misled by them. Even if you have sent the very best examples obtainable, and taking the others as the worst that could be found, the average condition of the Vines is very much better than we were led to infer from the data supplied. Your letter is much more intelligible than the other we received, and it indicates that you have a good general knowledge of Vine culture. You proceeded cautiously and wisely in the work of renovation. It is quite natural that your employer would not like being without Grapes for a year, and you did the best you could to provide some; and now we understand the case we do not suppose the crop would do any material harm. It is always advisable to allow Vines, as far as possible, to start into growth naturally after much disturbance of the roots, even if extra heat has to be provided afterwards, when new roots are working in the soil, to get the crops and wood ripe by the autumn. You are working at a disadvantage in a high cold dull district; the very large leaves you have sent show this clearly enough. They have not had sufficient sun to elaborate the crude sap, hence their enlargement and the softness of the tissue. The less the light the larger the leaf. Under such circumstances firm borders containing much calcareous and other gritty matter should be provided, and loose rich borders avoided. A multiplicity of surface roots should be the great object, as these are followed by sturdy growth and stout leaves; and whatever extra support may be required for the crops can be applied from the surface. It is also very important that the Vines and laterals be thinly trained. Not a leaf should be permitted to form that cannot develop under the direct action of light. There must not be the slightest suspicion of overcrowding, while all the air possible must be admitted consistently with avoiding sharp currents, even if a little extra fire heat has to be employed to maintain the requisite temperature. If you have erred at all it has been in keeping the house too close or the leaves too crowded, we cannot tell which; but we know there has not been sufficient light and air for perfecting them and enabling them to do their important work. We have observed that where there are frequent changes of gardeners there are, as a rule, unsatisfactory Vines. We are convinced the Vines referred to will improve under your management, as your past experience with them will be turned to account in a manner adapted to their peculiar

condition; a stranger would have all this to learn, and in the meantime it would be a mere matter of chance if the Vines did not suffer. That is the reason that Grapes are rarely satisfactory when many different persons share in their management.

Names of Fruits (A. B.).—1, Rymer; 2, Williams' Bon Chrétien; 3, Unknown, worthless. (W. M. Rose).—Early Julyan. (Geo. Wall).—Apple Summer Whorle; Fig, Brunswick; Plum, Blue Perdrigon. (A. J. Brown).—No. 1, Early Albert; 2, The fruit was much bruised and its acidity rendered part of the writing on the label illegible. If the flowers are large it is Early Victoria. (X., Loughgall).—We have never heard of an Apple called Assyrian Codlin. The name must be a corruption of some other, and yet in all our investigations we cannot find one that has any resemblance to it.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (H. Brown).—Staphylea pinnata, the Bladder Nut, the seeds of which being hard are strung by Roman Catholics for beads in some countries. (A. H., Hitchin).—Had the specimens been sent in a small box with a little damp moss, green grass, or fresh leaves, as we have many times advised, there would have been no difficulty in naming them, but by affixing them to dry paper the moisture was extracted from them and they arrived very much in the state of dry hay. No. 1 we detect as Galega officinalis alba, 2 as Arabis alpina variegata; the other was withered and crushed beyond identification. We cannot answer questions by post. (G. S.).—Adiantum trapeziforme; 2, Asplenium bulbiferum; 3, A. Fabianum; 4, Blechnum braziliense; 5, Gleichenia speluncæ; 6, Selaginella Martensi variegata.

COVENT GARDEN MARKET.—SEPTEMBER 2ND.

SOFT fruit is now finished in our market, and hard goods are in heavy supply, with prices falling, large consignments of Grapes and Tomatoes reaching us from the Channel Islands being easily cleared at low rates.

THE CLERGYMAN'S FARM.

(Continued from page 196.)

PERMANENT pasture, though last on our list of green crops, is in its way of equal importance with any of them. Of far greater importance, many a farmer would say even now; and it is still not uncommon to meet with the clause in agreements between landlord and tenant which directs that no pasture shall be broken up under a penalty of £10 per acre, and yet there is no branch of farming that has been so mismanaged as this. Easy-going ignorance and carelessness may be said to be the chief causes of this—ignorance of the relative value of the different sorts of Grass and Clover, and carelessness about the component parts of old pastures. So long as the sward was thick and interlaced with growth, but little attention was given to the actual value of that growth as an article of food, and yet how frequently did it

consist of native grasses and weeds! The maintenance of some three or four sheep per acre was the utmost limit of its capacity, and if it was made into hay it was poor and innutritious, and the aftermath failed to impart that improvement to the milk of the dairy cows which is always obtained from really rich pasture. Rushes, Carnation Grass, and other coarse herbage was also frequently very prevalent, and this state of things was taken so entirely as a matter of course that we once heard the owner of a large estate say in a speech at a meeting of farmers, that he should be much obliged to anyone who could tell him how to get rid of coarse worthless herbage out of his meadows.

How are we to reclaim such poor pasture? Seedsmen offer us a tempting "renovating mixture," by the sowing of which we are told we shall effect a radical change in the quality of the pasture. But can we possibly suppose that even if the seed germinates, the roots of the seedlings will be able to become established in the soil, which is already crowded with the tough fibrous roots of native plants? No, we will waste neither time nor money upon such doubtful practice; the unprofitable old pasture is condemned as worthless, and is got rid of as quickly as possible. The turf is pared, burnt, and the ashes spread over the surface, especial care being taken to let the burning follow the paring quickly, in order that the larva of insects as well as the seeds of weeds may be destroyed. If necessary, drainage is then seen to; ploughing follows—not mere shallow ploughing with two horses, but deep ploughing, either with four horses, or, if practicable, with steam tackle. August and September are the best months for this work, and the sowing of the seed is left till the following spring. It is not done then at any particular time, but we wait till the soil is dry enough to be well worked and reduced to a fine tilth, so as to keep the seeds near the surface, and the sowing is then done, either with the grass mixture alone, or with white Mustard, to be eaten off by forward lambs. Most farmers are accustomed to sow the grass seed with a corn crop. In alternate husbandry, for a two or three-years layer, we do not object to the corn, but for permanent pasture it is so important to give the young plants a good start in soil well stored with fertility, that we regard a corn crop as decidedly objectionable. A green crop of brief duration, like white Mustard, does no harm, and the fact of its consumption by lambs in folds points to a valuable addition to the fertility of the soil, and to the young pasture having a favourable start. It is our treatment of the young growth during the first two years which determines its success or failure. We know that if we allow the young plants to grow unchecked, and to bear seed, that many will cease to exist after the first season. We also know that if sheep are turned in to roam about the new pasture at will, they consume some favourite sorts of grass and leave others untouched. We therefore pass forward lambs quickly over it, in such small folds that the whole of the herbage is eaten and new folds made every morning, and the lambs are passed from fold to fold, and are not suffered to leave them, but are taken away from the last fold to another meadow. They are again folded upon the young pasture as soon as it has made new growth, so that it is not let run up to seed, and no sheep are left upon it after the end of September. In the following spring old sheep are folded upon it, or the breeding flock is passed over it—always in folds; and this system of folding is continued throughout the second year, or rather till October, when the sheep are withdrawn again, and it is left untouched till the beginning of another season of growth, when we must decide whether we shall use it for grazing or hold it in reserve for hay. If it is kept for hay it is mown first, before older pasture, so as to prevent any of the grass from seed-development, the best time being just as it is coming into bloom, and if all has gone well we shall be well rewarded for our pains by a fine crop of hay and a flourishing thick carpet of grasses and Clover, altogether superior to the poor herbage of the old pasture.

Surely systematic treatment is as important for this as for any other crop, and it is simply owing to the want of it that failure or poor results follow the laying down of land to permanent pasture. For the process that we have thus briefly sketched is similar to that which should be followed in the laying down of any land, the points of most importance being well-drained fertile soil, a clean seed bed, a fine tilth, genuine seed sown without a corn crop, and careful management for the first two or three years. It is obvious that in passing sheep over the young pasture in folds for the first two years, the growth is eaten fairly, and the land enriched without an outlay for artificial or other manure, and sheep may still be regarded as the most profitable animals upon a farm, having regard to small profits and quick returns. It may be said that all profits in farming are now small, and this important fact should induce a closer looking after so-called trifles, and due attention to every detail of our work.

(To be continued.)

WORK ON THE HOME FARM.

Harvest work has been somewhat hindered by rain, which was much wanted for grass and root crops, and it has done much good to Barley and no harm to any other corn. On the whole we are in the enjoyment of favourable harvest weather, corn ricks grow in number daily, and another week of fair weather will enable us to finish. Barley in exposed positions has suffered much from high wind. The straw was so sturdy that it was not lodged, but the ears were beaten off so much that stubble pigs find plenty of food there. As the pressure of harvest work ends, foul land will immediately be taken in hand, men with steel forks being set to fork out thick beds of couch grass, and horses used for the same purpose with horse hoes, cultivator harrows, and where land is very foul with ploughs too. Our best efforts should be given to turn every opportunity to account for getting the land clean, and now that we are upon this subject let us ask for more attention to the eradication of Thistles. The term is certainly appropriate, for the literal meaning of eradicate is to pull up by the roots, which is precisely what we would fain do to the Thistles. We have recently taken a farm in hand that is badly infested with them, and we find that it had come to be taken quite as a matter of course that there should be Thistles upon the land. Our resolution to get rid of them will cost us some trouble, for some two hundred acres may be said to be one huge Thistle bed. Where pulling is practicable it shall be done, but upon all firm land a little sulphuric acid will be poured upon every crown. This will be a tedious but thorough process, and we had far better do this than try to keep down this pest by means of hoeing and mowing. Old layers that are foul with couch grass will, if the weather holds fine, be pared and burnt, both to get rid of foul weeds and get a dressing of burnt soil and ashes for the land.

Stubble Turnips may still be sown, and we must take care to sow *Trifolium incarnatum* in September. On a clean stubble we simply sow the seed broadcast and harrow it in, but if the land is foul the horse hoe and harrows are first passed over it several times, and then the seed is sown. For neatness it is always well to clear the stubble first with harrows, and the short litter is taken into the yards. Let hedges be clipped and made trim for winter while the wood is soft with sap, and the work is easy, and let foul ditches or watercourses be cleared while the water is low in readiness for winter floods. Stockyards should be got ready for winter. See that drains are in good order, and the water supply is as good and abundant as possible. Let lodges be put in repair and washed inside with hot lime, and prepare an ample store of litter for hedging and for the yards.

REMARKS.

23rd.—Dull, cold, and autumnal.
24th.—Hazy early; fine and bright after
25th.—Fog in morning; fine after 11.30 A.M.
26th.—Cloudy early; fine and fairly bright afternoon and evening.
27th.—Rather heavy rain early, and slight till noon; brighter in afternoon; cloudy evening.
28th.—Fair, but not much sunshine; rather windy.
29th.—Windy early, with occasional cloud and sunshine; windy evening.
Temperature still slightly falling and weather continuing dry.—G. J. SYMONS

STRAWBERRY PLANTATIONS.

TO obtain a moderately fine crop of fruit, or a bountiful supply of strong runners suitable for layering into pots next year, new plantations should be made without delay. It is useless to depend upon old fruiting plants for an early supply of runners, for they cannot be obtained whether the plants are growing on light or heavy soils, as the strain of fruit-bearing prevents the production of early luxuriant runners.

The two past hot and dry seasons have proved beyond doubt the advantages of a young plantation, for without early runners it is impossible to have large well-developed crowns suitable for forcing. The plants layered from old fruiting stools are at the present time weak and puny, and will not make by the end of the season such strong plants and fine crowns as those possess now that have been layered from young plants. Our plants are strong, even luxuriant, and the large pots in which they were layered are already half filled with active roots.

Some contend that it is a waste of ground to have one plot for fruiting and another planted and reserved the first season to afford runners for forcing and planting a new plot early in the season. This is not the case, for a crop of Potatoes can be taken from the ground before the runners need be planted; and between these, say if planted 3 feet apart, may be had a row of Veitch's Autumn Giant Cauliflowers or Early Autumn Broccoli, which need not interfere with the Strawberries. When this practice is followed the Strawberries are planted down the centre of the Potato rows 9 inches apart, every alternate plant being lifted as soon as the Cauliflowers, &c., are cleared from the ground and planted in their place, which leaves the Strawberries 18 inches apart each way. Here this practice is not followed, simply because the principal kitchen garden is too far away, and would therefore entail too much labour; in addition the supply of water is inadequate and by no means convenient. Under these circumstances two plots in the fruit garden are available for Strawberries, and as soon as the fruit has been gathered the plants are destroyed and young plants are placed in for early runners for layering in pots and supplying the plantation the following year.

After the ground is prepared we plant, between every two rows of Strawberries, one row of Coleworts or Endive. If the ground has been prepared before the Strawberry plants are ready the Coleworts are placed in, the latter being planted when ready. In spring Lettuces raised in heat are planted out between the rows, and often seed is sown between them; if not to stand until they are ready, for cutting for transplanting elsewhere. Cabbages, Broccoli, or Brussels Sprouts are often sown as well. It will thus be seen that no space is really wasted, and even if no autumn or spring crop could be taken the advantages of having good early runners where the forced crop is of the utmost importance abundantly repay both for the ground and labour.

Our plants for this purpose were formerly prepared by

No. 272. —VOL. XI., THIRD SERIES

layering in small pots after the whole of those required for fruiting had been layered. This was abandoned, the young plants being cut off and inserted as cuttings in 3-inch pots and placed in a frame or a Peach house from which the fruit had been gathered until established; they were then hardened and placed out. This system is not now practised. A little light soil, principally leaf mould, is placed in a cold frame, and the runners are taken and dibbled into the soil. After a good watering they are kept close shaded from the sun for a week, by which time they have commenced rooting freely. The plants are then gradually hardened and ready for placing out a little more than a fortnight after they have been severed from the parent plant. The plants root much more quickly under the close moist conditions of the frame than they do when layered into small pots, which entails double the labour in watering. The plants can with a little care be easily lifted with a good ball of roots, and if planted during showery weather never suffer, but are strong and well established before winter. Those who have not practised this system should do so at once, for there is yet ample time to get the plants thoroughly established, even if they are only now severed from the parent plants.

If the plants are not wanted specially for supplying runners for forcing they will, if got in early, produce a good crop of fruit the first season after planting. When required solely for this purpose they should be placed the distance apart advised from row to row, and 9 inches only from plant to plant, which will allow of every alternate one being removed after the fruit has been gathered. Perhaps many readers may not have the convenience of a frame in which to start their Strawberries, and under these circumstances it is best to leave them attached to the parent until they have rooted into the border, in which condition they are ready for planting any time during showery weather.

The ground should be well prepared for this crop in readiness for planting, and not left until showery weather, and the plants are ready for placing out. The ground should be deeply dug and heavily manured, incorporating the manure well with the soil, so that the roots will have a chance of reaching at least a portion of it as soon as they commence to grow and extend. It is by no means an uncommon practice to turn the manure just below the surface, or go to the opposite extreme and bury it too deeply, thus being of little or no service to the plants for the first twelve months. Many cultivators trench the ground, but my experience of trenched ground for this crop has been very unsatisfactory, and it is not attempted here on our light sandy soil, but this has been rendered much heavier during the past few years by the addition of large quantities of clay. This has improved the ground very much for Strawberry-growing, being much more retentive of moisture than formerly, and the crop does much better in consequence. All who have light sandy soil for this crop should use clay liberally if they can procure it. Our practice is to spread it on to the ground in autumn after planting, and leave it exposed until spring, by which time it has fallen to pieces, and is then stirred into the surface. I find that it incorporates better with the soil by this than any other method.

The preference is given to cow manure in nearly a fresh condition for our soil, and this is most liberally used when the ground is dug. In spring, after the plants have commenced growing, the dressing of manure is supplemented by a good application of sewage, which is stirred or forked lightly into the surface the following day, and then left to be washed in by rains. If the weather, however, should prove dry, warm, and genial, a good soaking of water is given and the surface of the ground is mulched with old Mushroom bed refuse, leaves, or any similar material that may be at hand. This also assists Lettuces or other crops that may be growing between the rows. The mulching prevents evaporation, and even during the past two years we have had abundance of early strong runners.

No. 1928. —VOL. LXXIII., OLD SERIES.

¶ When the plantation is made after Potatoes are lifted the ground should be well manured, digging it in the same as if the plot was clear. This will not hurt the Cauliflowers or Broccoli growing between, the space upon which they are growing being manured directly they are removed. Strawberries will do on the same ground for years in succession, one of our flats not having been changed for ten years, neither has the ground been trenched during that period, and for how long before I have no means of ascertaining. It will thus be seen that our system of culture is runners the first season, a crop of fruit the following, and then the plantation is renewed.—WM. BARDNEY.

CYPRIPEDIUM STONEI.

THIS Orchid Slipper is worth a place in all gardens where these popular flowers are appreciated and the requisite heat can be provided. Imported and small partly-established plants are cheap, and therefore within the reach of all. The scape carries two or three flowers, according to the strength of the plant. These rise well above the dark green foliage, and last a long time, either cut or upon the plant. The flowers are much more useful for cutting than is the case with many kinds of a heavier nature, of which *C. Parishii* may be noted as an example.

C. Stonei does well, in fact grows luxuriantly, in a stove where a general collection of plants is accommodated. The amount of heat, shade, air, and moisture usually given to these plants where properly grown, appears to suit this *Cypripedium* exactly. It should be grown in a pot or pan liberally drained, and in a compost of fibry peat and sphagnum moss in equal proportions, with charcoal in lumps freely intermixed. It will also grow freely in fibrous loam, sand, and charcoal, but this compost is only safe in the hands of skilful cultivators, for it is liable to become sour quickly. Good peat fibre from which the particles of soil have been removed will last in good condition for at least two years. The system of potting that will be recommended may be safely followed with certainty that the compost used is in a perfectly sweet condition about the roots of the plant.

The secret of growing not only this, but all *Cypripediums*, is to retain the medium in which their roots are working sweet and healthy. The pots or pans used should be at least three parts full of drainage, carefully arranged with the hollow side downwards, and over these a thin layer of living sphagnum moss. Peat fibre will answer the same purpose, and this is preferable on account of its lasting qualities. The pot, almost level to its rim, should be filled entirely with peat fibre and charcoal, carefully worked amongst the roots, no moss being used. The remaining portion, or all that is placed above the rim of the pot, should consist of the peat fibre, sphagnum moss in a living state, and charcoal, mixed together, with a good layer of the moss on the surface, which should be induced to grow freely. By this method of potting, the moss, which decomposes in a season, can be picked out every spring just as growth commences and new supplied. The moss need only be removed the first season after potting, and the fibre as well the following season—that is, the whole above the rim of the pot. This will insure the roots, or at the least the majority of them, being in perfectly fresh sweet material until the plants require repotting, or larger pots, which will be the case after the second year if they grow and do well. When repotting them every particle of the compost used should be removed from amongst the roots and replaced with new, which will insure the plants remaining perfectly healthy provided the other treatment is satisfactory.

While growing, this plant requires abundance of water both over the foliage and at the roots; in fact at no season of the year should the material about the roots be allowed to become dry. Great care should be exercised not to apply cold water direct from the main, either to the foliage or the roots, or the foliage of this variety will spot, which disfigures them.

The foliage should be kept perfectly free from insects, and grown in a winter temperature of 60° to 65° by night, with a rise of 5° or 10° by day. During summer the night temperature should range from 70° to 75°, with a corresponding rise of 10° or 15°, or even more by sun heat after the house has been closed.—S. A.

JUDGING AT EXHIBITIONS.

[A paper read before the Dundee Horticultural Society by Mr. W. Williamson, Tarvet House Gardens, Cupar, Fifeshire.]

BEFORE proceeding to the chief object of this paper it may not be considered out of place if we glance at a few facts concerning exhibitions in general, in order, if possible, to ascertain if they are productive of the

good expected from them. To consider any means by which their popularity might be enhanced, to notice some objections urged against them, and see if any of them are well founded, to make plain to employers the benefit they derive from granting to their gardeners the liberty of a reasonable amount of competition, and above all to clear away as far as we can any misunderstanding or difference existing between judges and exhibitors.

As to the principle of exhibitions, there can scarcely be two opinions. Everyone must admit they have been the means of increasing not only the quantity but the quality of every art and industry which by their agency has been placed in public competition. Through the same influence the minds of men have been so exercised in trying ways to excel as to call forth their highest intellectual powers to aid them, the benefits accruing not only to themselves, but to all. Exhibitions have indeed done much to advance the social and intellectual benefit of the community. Our attention at the present time shall be directed to horticultural exhibitions, a careful inspection of one of those of average importance being to most people not only a certain pleasure, but a great source of instruction. The greatest benefit is derived from a survey of the productions of others, to which the energy and skill of brother craftsmen have been unsparingly applied, producing results which if we cannot exceed we try our best to imitate. The outcome of all this effort and acquisition of knowledge must be to increase production, enhance the value, and give a fair return for the labour.

Let us notice some objections put forward against exhibiting; happily there are few, but they are important. In the case of fruit, so-called undercropping is the principal complaint. If we change the word to moderate cropping we arrive at the true description. Every gardener of any intelligence at all knows quite well that to take less fruit from a tree than what it can bear and bring to perfection is very unwise and useless. If we take the case of the Vine, it is well known a strong healthy plant will produce and mature with good management a given quantity of fruit as well as half that quantity—that is to say, if a Vine has a crop of 30 lbs. of well-finished fruit it would have been a gross mistake to have allowed 13 lbs. only to remain upon it. The same rule applies to flowers and all divisions of the vegetable kingdom. It is quite clear, however, that cropping Vines or fruit trees at what we might call the exhibition standard, instead of being detrimental, is actually healthful and economical. Another objection adduced is that men who exhibit give their time and best attention to those plants, fruit, or flowers on which they are to stake their reputation at the next exhibition. This may be well founded in some cases, but we always find exhibitors enthusiasts in the profession, and if they have strength suited to the requirements of the garden, there is seldom any cause for complaint. The last of the objections to exhibiting I would notice is a very formidable one—namely, proprietors who take a little pride in their gardens, and who naturally suppose the produce from them ought to be as good as their neighbours, on finding their exhibits placed second or third in the prize list resolve to give it up altogether rather than risk the chance of defeat again. They do not seem to take into consideration the means employed, the facilities given for production, or the obvious fact that all cannot be first. Gardeners ought to exercise critical observation on what they are to exhibit, and see that they are worthy of the space allotted to them. The practice of competing in a great number of classes with the expectation that “they will come in somewhere” should be discouraged, as it lowers the standard of general excellency and causes dissatisfaction to everyone. It is not within the reach of an individual to give the necessary attention to so much, and to try to do so would interfere with the legitimate requirements of any establishment, giving rise to some of the objections previously alluded to.

Having said so much on the benefits derived from and objections taken to exhibitions I would now refer to the judges. They ought to possess the necessary qualifications to enable them to adjudicate correctly upon the exhibits placed before them. They should be able to make a quick comparison, to detect at once the weak and strong points, should have a clear understanding of the different points of excellence in the varieties. The selection of judges is a matter of special importance as bearing on the success of an exhibition. The general assumption is that men occupying the position of head gardener in large establishments are qualified to adjudicate at any show. Such men are generally excellent gardeners, but that does not imply that they will be equally good judges. The best judges are to be found where certain classes of plants, fruits, and flowers are specially grown; where the highest state of perfection is reached, and the essential points of quality obtained. But men from such positions can only be said to be competent as judges in the department to which they have devoted attention, and should be appointed to adjudicate in that section of the show. By this arrangement in selection fewer judges would be necessary. This rule can only be adopted by societies in large centres, where the show is extensive and a number of judges requisite. Judges should receive no pay for their work except expenses; in fact, it ought to be considered a labour of love and a privilege to have the opportunity of doing a little service in promoting a taste for the cultivation of fruits and flowers. The officials of a society having obtained men qualified for the work, it becomes the competitors to acquiesce in the decisions, and submit with the best grace possible.

In offering the following suggestions and criticisms on judging it is strictly with the purpose of endeavouring to bring into conformity much controversial matter and disputed points which invariably arise during the labours of judges, and to seek to bring into harmony the views of exhibitors and judges to the characteristic points of merit in the different genera and varieties of plants, fruit and vegetables. I intend discussing

fruit and vegetables more particularly than plants and cut flowers at present, and would begin by alluding to what I may call a new departure in point-judging. It has occurred to me and many others that by the system of point judging at present practised real justice, where the competition is very close, is next to an impossibility. Judges generally prefer to use as few points as possible to save embarrassment and difficulty, hence the necessity of devising some means whereby a greater number may be used, and all doubt as to their application be removed. Some take one number of points and some another, say from four to nine as a maximum. The latter number would not do justice to a collection of eight varieties of fruit, far less twelve or fifteen. I will give one instance of the difficulty in registering the difference in value of two varieties of fruit in a mixed collection. Suppose it to be Peaches, and four points allowed for excellent fruit, these dishes being, we may say, almost equal; the only way then for the judge is to give the one the full complement, the other a point less, consequently bringing it down to the next grade, or on a level with Plums, Pears, or Apricots, for the want of some fractional part wherewith to place it in its proper position in relation to the other dish, or its true representative value as a part of the collection. In order to meet this any way of dividing points into fractional parts might be of advantage. Meanwhile, I propose a system for consideration which, if it were adopted, would as near as possible give every dish or exhibit its proper value—viz., by giving a certain number of marks for every sort, according to its relative value, assigning one mark to lowest, two to the next, so on till the whole are represented with the number approaching nearest their intrinsic or commercial worth, four points being the value of one mark.

I will try to explain this plan of judging by pointing out the merits of two imaginary collections of twelve varieties of fruit. These twenty-four dishes shall be not only all different varieties, but nearly separate sorts or genera, and represent nearly every sort of fruit generally grown and shown at our exhibitions. The collections shall be designated A and B, and consist of the following—Pine Apple, two dishes of Grapes, Melon, Peaches, Nectarines, Figs, Apricots, Pears, Plums, Apples, Cherries. We will suppose these fruits to be perfect examples of their kind, equal in cultivation, so that the work of judging them is narrowed down to the quality and appearance peculiar to each. Before proceeding to their work the judges should be supplied with ruled cards, having space on the left for names, then two columns, the one for marks, the other for points, with space on the right for remarks. When the judging has been completed the number of marks and points are added separately, the marks multiplied by four, taking in the points; the total points are then subtracted to find the difference between the collections. The judges would also have to settle before commencing the maximum number of marks to be given to each sort according to the esteem in which they are held as dessert fruits in the manner I will now describe in going over the collections. Someone may be apt to doubt whether four points are not too many to allow between, say, good Cherries and Apples, or any of the other kinds, but the effect of such difference is more apparent than real, from the large number of points employed through the whole collection. The highest possible number in the collection we have been considering is 112 points, not counting those kinds separately that receive an equal number of marks.

In the following tables the fruits are in each case named in this order—Pine, Grapes, Melon, Peach, Nectarine, Fig, Apricot, Pear, Plum, Apple, and Cherry, the "marks" in the first column showing the comparative value of the respective varieties, and the "points" in the second column the merit of the fruits shown, the difference in favour of Collection A being two points.

	184				

I will now pass on to a collection of eight varieties of Grapes, four black and four white, but instead of using six marks as we did for Grapes in the collection of mixed fruit, three will be the number; as all are of the same class there is abundant scope to decide between good, bad, and indifferent. A rule to guide in assigning the marks to collections of plants, fruit, or vegetables, is their number, variety, and inequality of pro-

perties or values. Three marks should be the number employed for all collections of subjects belonging to the same order or class.

Before passing judgment on the merits of eight varieties of Grapes we will consider what the properties of a model bunch are. As to shape, some kinds are about as broad at the point as the shoulder; others, again, are broad and short. We will take the mean between these two extremes as a model of shape, say breadth at shoulders equal to two-thirds of its length, tapering downwards. Berries large, regular, well formed, and thickly coated with bloom. No footstalks or stems to be seen, unless the part attached to the wood supporting the bunch, which should be short and thick. The bunch itself to be compact, free from all blemishes of spot, rust, or rubbing.

The first matter in judging Grapes is to select and put against each other the best in point of cultivation and similarity. We will have at present the same varieties in opposition, that we may discuss their merits from a cultural standpoint, and it must not be supposed I disregard the importance of certain other varieties of Grapes, such as Gros Colman, Alicante, Lady Downe's, &c., although I have not included any of them in this collection for this reason. Grapes valuable for their late keeping qualities should be discouraged for early autumn shows, because they are seldom ripe although well coloured, and it is injudicious to try to ripen them for that purpose. The collection will comprise the following varieties—Muscat of Alexandria, Duke of Buccleuch, Foster's Seedling, Buckland Sweetwater, Madresfield Court, Black Hamburgh, Muscat Hamburgh, and Black Prince. These are all early or medium sorts, and well known.

COLLECTION A.			COLLECTION B.

	4			4	
	83			84	
				83	

In favour of B, one point.

We will take Muscat of Alexandria first. The one in A collection is a perfect 4 lb. bunch, large equal berries, amber colour, entitled to the full complement of marks. The one in B collection, same size of bunch and berry, but wanting in colour to the extent of two points, A 3, B 2 2. The next is Duke of Buccleuch, both bunches equal in colour and size of berry, but that of B the larger of the two, A 2 3, B 3. Foster's Seedling comes next; it is not at the present a very handsome variety, and we will not consider it first-class here; the one in A collection a fair example, but not deserving of the highest value, say 2 2, that in B collection a shade behind the other, 2 1. Buckland Sweetwater, A good bunch, 2 3; B scarcely so well coloured, 2 2. Madresfield Court, a variety gaining favour every year as its cultivation is being better understood, comes next. Here B has a first-class example, large in bunch and berry, highly finished, receives full value; A is behind both in size of berry and thinner bloom, placing it two points behind the other; thus B 3, A 2 2. Black Hamburgh, the most common and useful of Grapes; A and B have both good, full, well-proportioned bunches, B has the best in point of colour; B 3, A 2 2. Muscat Hamburgh, a Grape of high quality, but not so easily grown as the Black Hamburgh; B's bunch is good, A's is equally good, a little loose; B 3, A 2 3. The last is Black Prince, a very good Sweetwater Grape, these two bunches are below the standard; A 4 points, B 5, then A 2, B 1 3.

(To be continued.)

ONCIDIUM INCURVUM.

WHERE fragrant Orchids are esteemed this should be accorded a place, in fact it is worth a position in any collection however limited. Its small mauve and white flowers are produced on a branched slender stem 3 or 4 feet in length, more than 2 feet of its length being covered with flowers. One good spike or two will perfume the air of a moderately sized house, and are most effective either for decoration or cutting, as the spikes are light and droop gracefully. It does well at the warmest end of the Odontoglossum house, and will succeed either in a pot or basket, the former being preferable if stage room is plentiful; if not, it can be most successfully cultivated in a basket suspended from the roof.

If grown in pots they should be filled at least half full of

drainage, for it is essential to make provision for the water supplied to pass away freely. If the soil is allowed to become sour or saturated, this variety soon presents a yellow sickly appearance which is unnatural to it, for when doing well the foliage is deep green in colour. The material used for potting should be peat fibre, which, if good, will be found to last in a healthy condition for several years. Charcoal in lumps may with advantage be used, and a little living sphagnum moss on the surface. The roots evidently like the moss, and are not long before they take full possession of it; but it is not wise to use it mixed with the peat for potting, because it decays too quickly and cannot be removed without disturbing the roots of the plants too much, and therefore causing an unnecessary check annually. When the moss is used only on the surface the majority can readily be removed when repotting or top-dressing the plants that may be grown in the same house. Potting and top-dressing is best done just as signs of growth are visible.

When the roots are active and growth luxuriant, liberal supplies of water should be given, but the supply must be gradually diminished as growth is being perfected. The supply in spring must also be as judiciously increased as the growth progresses. During the resting season very little water is needed, in fact only sufficient to keep the pseudo bulbs fresh and plump. If the soil about the roots is kept in a moist condition during the resting period they are very liable to perish, and in addition the plants do not receive a complete period of rest. This is essential if they are to bloom profusely and grow luxuriantly the following season. The longer the season of inactivity the better the plants flower and grow afterwards. A fair amount of light should be given, or the foliage draws up rather weakly. The amount of shade frequently given to *Odontoglossums* is rather too heavy for this *Oncidium*, but this can easily be managed by placing the plants of this variety in the lightest position the house affords. Light towards the close of the summer and in early autumn is of vital importance to mature the pseudo-bulbs that have been made.

This Orchid flowers freely in a young small state, but it is surprising how flowering retards the growth and progress of the plants, and therefore it is unwise to allow them to flower until they attain some strength. The flower spikes are a very long time developing, for they frequently make their appearance in spring, and five or six months usually elapse, under cool treatment, before the flowers are fully expanded.—W. D.

CONES AND BERRIES.

SOME are of opinion that a plentiful supply of fruit on the trees is a sure sign of a severe winter, but this is very rarely verified. I have noticed some extra severe winters occur when there were no Holly berries and other tree fruits were scarce, and the mildest winters are often preceded by extra heavy crops of fruit. No one need infer that we are certain to have a severe winter because berries are wonderfully plentiful this season. I cannot remember a time when they were more abundant, and I think the credit may be given to the fine summer of 1884, and the equally fine one of this year. The Mountain Ash was amongst the first of our trees to ripen its fruits. They came in huge clusters, and when ripe were exceedingly showy, but the birds soon demolished them. *Berberis Darwinii* was the next to mature, and the crop was wonderful. When this valuable bush is covered with its beautiful deep golden blossoms in early spring it is exceedingly pretty, but it is equally admirable when the multitude of berries gain their deep glaucous purple hue in summer. The Hawthorn trees are fruiting abundantly, and Sloes and Nuts have full crops. The Holly trees are heavily laden with fruit in all positions, and Christmas berries will be most abundant this time. Some years I have seen our crops of these very partial, a tree in the open, or only one here and there producing fruit; but this season they are fruiting in sunshine and shade, and the branches are already bending down with their excessive load. The Arbutus and the Sweet Bay are also fruiting freely, and every tree which bears fruit appears to be unusually prolific just now. It is a pretty sight to see them with their heavy rich crops, and many of them are equally as attractive in fruit as they were in blossom.

The Conifers are also extra fruitful. The *Wellingtonia gigantea* in two instances here is producing many cones, and so is the Japanese Cedar, *Cryptomeria japonica*. *Araucaria imbricata* is producing cones in an unusually free manner, and the *Abies* and *Pinus* are very fruitful. The Stone Pine, *C. pinea*, bears cones pretty freely every year, but it is certainly more prolific than usual this season. I have noticed that more of the old cones have fallen off lately than usual, and it is very gratifying to observe that they are being succeeded by such quantities of fine young ones.—J. MUIR, *Margam Park, S. Wales.*

AMONGST THE NOVELTIES.

I wish to add a word or two to what I have written anent the novelties. I omitted to mention Early Milan Turnip, which I found an extremely handsome variety and the quickest grower I ever tried. Planted same day as Snowball, they were fourteen days earlier, but when

cooked I found them rather hither. It has a very small neat top and is strap-leaved.

Veitch's Perfect Gem Lettuce I also omitted. It is very good for the summer, for it does not readily run to seed, and is of good quality. The leaves are of a very deep green colour, and it is very taking in appearance.

Girtford Giant Runner Bean.—Evidently I have not this variety true. Mr. Gilbert has quietly and severely reproved me for thinking badly of it by sending me by post four splendid Bean pods 8 inches long, as straight as a rule, and as tender as a chicken—better Beans I never saw. He did not write a line to say they were Girtford Giant, but no doubt they are, and that being the case it is a Bean well worth growing.

Sharpe's Victor Potato cannot be surpassed for frame work or earliness, combined with high quality, productiveness, and beauty. It is not a novelty exactly, but I am glad to recommend it. I see Mr. Laxton has a white Beauty of Hebron, which has done well. Sharpe's Duke of Albany is a white Beauty of Hebron also. The foliage, also shape, appearance, and when cooked quality, are identical with Beauty of Hebron. The colour, however, is white, which is an improvement. This year, however, some have thrown back to their parent, and one pink and white. It is a productive and good Potato.—H. S. EASTY.

INSECTS AND FRUIT TREE CANKER.

FURTHER investigation and experiments have strengthened and confirmed my previous experience—viz., that insects, and insects alone, are the first and only cause of canker in fruit trees. In confirmation of my views, and as a result of my experiments, I have to-day sent a parcel containing specimens of both Apple and Pear trees treated as I advised, containing specimens of fruit and the cankered places, especially on the Jargonelle Pear, where you will see the bough was almost deprived of sap communication; but by trimming out every bit of bark containing insects and dressing the place with Gishurst compound or soft soap, the bark recovered sufficiently to grow and bear well. The wonder is that such a small bit of bark would allow sufficient sap to support the bough some 6 or 8 feet long and the fruit. I am fully convinced that the bough would have died had it not been attended to, as the other specimens have, as shown, while others are lingering.

The best Apples sent are from a tree which was about the worst case of canker I had, but by my treatment, without disturbing a root, or without a handful of fresh soil or anything else, except a top-dressing of manure, which all get alike, I have not a healthier tree on the place. The five Apples are from a bough about 2 feet 6 inches long, which is carrying nineteen more of similar size. The other sample of small Apples are from the next tree, of the same kind, similar situation, subsoil, drainage, top-dressing, &c., but the cankered places are not cut out, and the insects have full possession, and are gradually devouring the life out of it; but by my treatment I have not the slightest doubt that I could restore it to the same state of health as the other without disturbing a root.

Last winter I had specimens of cankered Apple trees from the Channel Islands, Ireland, and several parts of England, and in every case I found the same insect agency at work, and succeeded in getting one under the microscope on a rule measuring one-two hundredths of an inch. They are so small that nobody would notice them. My reason for writing is that I thought the specimens would interest you, and the specimen of Jargonelles would possibly interest persons at the Pear Conference if introduced.—J. HAM.

[The canker in the case of the Pear branch appears complete, and we are glad to see it, and the sufficiency of the narrow sap channel, about an eighth of an inch in width, is remarkable. We are fully aware of the spread of canker when no steps are taken to prevent it, and of the presence of insects. The question is, Are they the cause or the consequence of the canker? We are open to receive expressions of opinion on this subject, and are obliged to our correspondent for his investigations.]

THE SAGO PALM.

SAGO is nearly pure starch, obtained from various species of Indian Palms. In the Indian Archipelago it is procured from *Sagus Rumphii*, *Sagus lævis*, and *Sagus genuina*; on the Coromandel coast from *Phoenix farinifera*; in Ceylon from *Corypha umbraculifera*; and in Assam from *Caryota urens*.

These trees are cut down, and from the pith filling their stems the sago is extracted. The pith is thoroughly washed, and from the washing, when allowed to rest, the fecula or starch subsides; this is the sago flour of commerce, of which large quantities are used in the manufacture of calico. When used as food it is granulated, and known as pearl sago. Tapioca is really sago in lumps, and was so called merely because the French, who introduced it from India, named it *Sagou-tapioka*. About eight thousand tons of sago are annually imported.

Sagus Rumphii (fig. 38), is a small tree, comparatively speaking, not above 30 feet high. It is a native of the Indian Archipelago, particularly of Malacca, Borneo, Sumatra, Celebes, and the Moluccas. Before the tree has arrived at maturity the stem consists of a mere shell, about 2 inches thick, with a great mass of spongy pith, becoming gradually absorbed, and ultimately the stem remains hollow. At the time when the pith is

fully developed, and before it has begun to diminish, which is indicated by the superior leaves being covered with a sort of farina or white dust, the tree is felled, and the trunk cut into lengths of 6 or 7 feet long, which are split to admit of the pith being more easily removed. The pith is in the state of a coarse powder, and is mixed with water in a trough having a sieve at one end; the water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. The water is then strained off, and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. Sago, as it comes to this country, is prepared by forming the meal into a paste with water, and rubbing it into grains; it is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese

Madresfield Court if the former is really shown in finer condition than the latter?

The fact that the show is held in August or September is not the fault of exhibitors; and if they have fine Alicantes, why should they not get a reward for them, even though the season when they are best for use is far distant. If all Grapes were only shown when at their best for table use, Alicantes and Colman would never be exhibited before December, and Lady Downe's would never appear before March!

A fine, well-coloured, well-bloomed bunch of Alicantes shown in September is proof enough that the quality of the Grape will be good when used in, say, November or December. If superior in size, colour, and bloom to any bunch of Madresfield Court exhibited, why not give the Alicante the award?

If considerations such as Mr. Iggulden urges should be taken into account, were allowed to weigh with those who make up prize schedules,

Fig. 38.—SAGO PALM (*SAGUM RUMPHII*).

of Malacca refine it, so as to give it a fine pearly lustre, and large quantities are also prepared at Singapore. It is said that a single tree will yield from 500 to 600 lbs. of sago. Sago forms the principal food of the natives of the Moluccas. A decoction of sago fermented yields alcohol by distillation, and by ascension it forms vinegar. The fruit of this Palm is the size of a hen's egg. The base of the leafstalks is covered with long fibrous filaments, that serve to make cordage and sacking.

JUDGING GRAPES.

MR. IGGULDEN'S remarks on the above subject are very interesting, and there is sound advice contained in them on some of the points he discusses; but there are some of his remarks which appear to the writer hardly correct. For instance, when judges have to pass judgment on a number of black Grapes entered in a class for any other black variety, how can it be said that they are in error in placing Alicante before

there would be endless discussions as to when the different varieties should be allowed to compete. Granted that Alicante is easier grown than Madresfield Court, still, where great complexity is wished to be avoided in prize schedules, there can hardly be such distinctions drawn.

In shows where prizes for all the different varieties—or, at least, all those more generally grown—are offered, there is no ground for the complaint that a less ripe and more easily grown variety finds favour before one more fit for immediate use; but all societies cannot, or do not, care to afford such, and then recourse is had to the any other black variety, with the consequence that some growers are dissatisfied with judgments sometimes given.

If more shows were held about Christmas then there would not be the same excuse for showing late Grapes in August and September when not sufficiently ripe; but till such is the case there need not be any wonder displayed when people who have fine-looking Alicantes, Colman, or Lady Downe's show them in August or September in preference to not exhibiting them at all.

Errors in judging do occur, and sometimes gross ones; but that it is

an error to place Alicante before Madresfield Court at a show held in August or September simply because the former has not had time to attain its best edible condition, is not, in the opinion of the writer at least, correct. Size of bunch and berry, colour and bloom, being superior, why should Alicante go down before Madresfield Court simply because the latter has attained its edible qualities sooner than the other? There can be no doubt that as regards flavour Madresfield Court is superior to Alicante at all times, but that alone is not to be taken into account in a competition for "any other black variety." There can be no hard-and-fast rule laid down for Grape judging; common sense, knowledge, experience, and strict impartiality must be brought to bear, also a glance at circumstances that cause late Grapes not having attained their best as regards table qualities to be staged along with others that are more fit for use.—S.

A CLASSIFICATION OF GARDEN ROSES.

I WAS recently reminded how much a good general monograph of the genus *Rosa* is needed. Lindley's "Monograph" was published in the year 1820, and since then a great number of new species have been discovered, and a very large number of books and papers have been written bearing upon the subject in one way or another. The difficulty which one finds at the outset in using Lindley's book is that his primary groups are characterised so briefly, and that the points of contrast which they present are not fully and clearly brought out into view. The following key shows the best way of getting over these difficulties, which, after having had a large number of specimens through my hands during the last thirty years, I am able to suggest. The list of species is only intended to be exhaustive so far as garden Roses are concerned, with the addition of a few well-marked types not yet brought into cultivation. What I have aimed at is to give a separate number to well-marked types only, and to place under these the subspecies and varieties into which they deviate. Of course I am well aware that in *Rosa*, of all genera, even if independent observers work from the same standing point, it is not in the least likely that any two of them will draw the line between species and subspecies in the same way. What follows must therefore be taken as a rough draft of a very condensed guide to the determination and classification of the garden types.

ANALYTICAL KEY TO THE GROUPS.

- Leaf simple, exstipulate. ... 1. SIMPLICIFOLIÆ.
 Leaf compound, stipulate.
 Styles forming a column, protruded beyond the disc. } 2. SYSTYLÆ.
 Styles not united nor protruded beyond the disc.
 Stipules nearly free, deciduous. ... 3. BANKSIANÆ.
 Stipules adnate above the middle, persistent.
 DIACANTHÆ.—Main prickles in pairs at the base of the leaves.
 Fruit persistently pilose. ... 4. BRACTEATÆ.
 Fruit glabrous. ... 5. CINNAMOMÆÆ.
 HETERACANTHÆ.—Prickles scattered, numerous, passing gradually into aciculi and setæ.
 Leaves not rugose; large prickles long and slender. } 6. PIMPINELLIFOLIÆ.
 Leaves rugose, coriaceous; large prickles short and stout. } 7. CENTIFOLIÆ.
 HOMOCANTHÆ.—Prickles scattered, comparatively few, subequal.
 Prickles slender; leaf not glandular below. ... 8. VILLOSE.
 Prickles stout and hooked; leaf not glandular below. } 9. CANINÆ.
 Leaves very glandular beneath. ... 10. RUBIGINOSÆ.

CLASSIFIED ENUMERATION OF THE GARDEN SPECIES AND SUBSPECIES

Group I. SIMPLICIFOLIÆ.

1. *R. simplicifolia*, Salisb. (= *R. berberifolia*, Pallas = *Lewea berberifolia* Lindl. = *Hultheimia berberifolia*, Dumont).—Siberia and Persia.
R. Hardii, Paxt.—A hybrid between *berberifolia* and *laxa*.

Group II. SYSTYLÆ.

2. *R. repens*, Scop. (*R. arvensis*, Huds.).—Europe.
capreolata, Neill (the Ayrshire Rose).
 3. *R. sempervirens*, Linn., South Europe and India.
prostrata, DC.
scandens, Miller.
Leschenaultiana, Tbohy and Redouté.
longicuspis, Bertol.
 4. *R. moschata*, Miller.—Southern Europe and India.
Dupontii, Desegl. (*nivea*, Dupont).
Brunonii, Lindl.
 5. *R. multiflora*, Thunb.—China and Japan.
polyantha, Siebold (*Lucæ*, Franch. and Rocheb.)
 6. *R. abyssinica*, R. Br. (*Schimperiana*, Hochst., and Steud.).—Abyssinia
 7. *R. phœnicea*, Boiss.—Orient.
 8. *R. setigera*, Michx. (*rubifolia*, R. Br.), the Prairie Rose—United States.
 9. *R. stylosa*, Desv. (*collina*, E. B.).—Europe.
leucenchroa, Desv.
systyla, Bast.
 Connects Groups II. and IX.

Group III. BANKSIANÆ.

11. *R. Banksiæ*, R. Br. (*inermis*, Roxb.).—China.
lutea, Lindl., *Bot. Reg.*, t. 1105.
 12. *R. microcarpa*, Lindl. (*amoyensis*, Hance).—China.

13. *R. Fortuneana*, Lindl. in Paxt. *Flow. Gard.*, t. 171.—China.
 14. *R. sinica*, Murr. (*lævigata*, Michx.; *ternata*, Poir.; *triphylla*, Roxb.; *nivea*, DC.; *cherokensis*, Donn.).—China.
hystrix, Lindl., *Mon.*, t. 17.

Group IV. BRACTEATÆ.

15. *R. bracteata*, Wendl. (the Macartney Rose).—China.
 16. *R. involucreta*, Roxb. (*Lyellii*, Lindl.; *palustris*, Hamilt.).—India.

Group V. CINNAMOMÆÆ.

In some of these there are only the pairs of prickles at the base of the leaves, but in several of the species there are few or many aciculi in addition. These latter form a connecting link between Groups V. and VI.

17. *R. cinnamomea*, Linn.—Europe and North Asia.
majalis, Retz.
davurica, Pallas.
 18. *R. carolina*, Linn. (*corymbosa*, Ehrh.; *pennsylvanica*, Michx.; *Hudsoniana*, Red.).—North America.
 19. *R. lucida*, Ehrh. (*baltica*, Roth.; *Rapa*, Bosc.).—North America.
 20. *R. humilis*, Marsh. (*parviflora*, Ehrh.).—North America.
 21. *R. nitida*, Willd.—North America.
 22. *R. laxa*, Retz. (*clinophylla*, Red.).—Siberia.
 23. *R. Woodsii*, Lindl. (*Maximiliani*, Nees).—North America, west side.
californica, C. and S.
pisocarpa, A. Gray.
Fendleri, Crépiau.
 24. *R. nutkana*, Presl.—North-west America.
 25. *R. gymnocarpa*, Nutt.—North America.
 26. *R. anserinaefolia*, Boiss.—Orient.
 27. *R. Fedtschenkoana*, Regel.—Central Asia.
 28. *R. rugosa*, Thunb. (*ferox*, Lawr.; *Regeliana*, Andre).—Japan and Siberia.
kamschatica, Vent.
 29. *R. sericea*, Lindl.—India.
 30. *R. microphylla*, Lindl.—China. Connects the Cinnamomæ and Bracteate.
R. Iwara, Siebold.—Supposed to be a hybrid between *rugosa* and *multiflora*.

Group VI. PIMPINELLIFOLIÆ.

31. *R. spinosissima*, L. (*pimpinellifolia*, L.; *scotica*, Miller).—Europe and Siberia.
altaica, Willd. (*grandiflora*, Lindl.).
myriacantha, DC.
 32. *R. Webbiana*, Wall.—Himalayas.
 33. *R. platyacantha*, Schrenk.—Central Asia.
 34. *R. rubella*, Smith.—Europe.
stricta, Donn.
gentilis, Sternb.
reversa, W. and K.
 These perhaps hybrids between *spinosissima* and *alpina*.
 35. *R. hibernica*, Sm.—Ireland and England. Perhaps a hybrid between *spinosissima* and *canina*.

A CHESHIRE FRUIT FARM.

"FARRALL's fruits always have command of the market." This was the popular expression at the market town where "Farmer Farrall" offered his produce. His Currants were plump and clean, the Black ones like Grapes, the Red ones like strings of coral, and the White ones transparent like big heads of amber. The Raspberries reminded one of trimble stands of purple velvet, so rich and luscious were the fruits, with such a delicate coating of bloom. Then the Strawberries. They were just perfection. Remarkable for size, colour, and flavour, it seemed impossible that anything could be better. Daintily packed in clean chip-wood quart punnets, arranged in large wooden trays, with all the freshness of the summer morning upon them, uncrushed and unbroken, one could not help but stay to admire, though a lingering look at such wares proved often a dangerous look, as it almost invariably ended in an investment. From the fruits themselves it is but a short step to fruit-growing, and enjoying a conversation with the "Farmer," we soon found we were talking to a thoroughly practical fruit-grower, who knew well what to do, when to do it, and how.

Availing myself of a spare evening, I paid a visit to the fruit farm from which such grand and encouraging results are obtained. Now, Cheshire has never had the reputation of being a very first-rate fruit county. The cheese tub rather than the orchard has been identified with the industry of Cheshire. As for Apples, well, there were plenty of Keswicks and other kinds "good for dumplings," but the orchard was allowed to grow its own fruit in its own way without care or cultivation, the dairymaid cook picking up the fruits from the ground as the wind scattered them to put them in their thick covering of flour and fat, and then the plethoric pudding was plunged into the boiler to await the return of men and lads with the keen appetite which one can find in the fields; and with the excellent sauce of hunger and health the smoking pile gradually became smaller and smaller until the iron spoon stood on the dish—the only thing uneaten. Under conditions such as these, believe me, the palate need not be tickled with fine flavours. Quantity is the first factor, quality is a secondary consideration. Hence the typical Cheshire Apple was a "gradely dumpling soart," but was not such as would commend itself to the pomologist or the fastidious connoisseur. Pears, too, in the older orchards were nothing much to boast of, grown mainly on old worn-out trees, mainly "Catherines" (Cattens as we called them in those days) with here and there a tall pyramidal "Bradford" of more recent introduction, or perhaps a tree here and there of Green Chisel, Swan's Egg, or Hessel where some attention was given to the cultivation of more kinds than were ordinarily found in the Farmer's garden. Of Plums we had either Winesours or Jacobs, and this was the Cheshire orchard. A Nut bush or two, a Cherry tree, and a "Brandy Apple" (a very shocking name locally bestowed upon the Red Quarrenden, presumably on account of its vinous flavour) might be found in some of the larger gardens, but these were not essentials.

The county, however, appears to have moved with the times, and the improvement is manifested in the marketing of fruits of better quality and in the increased demand for young fruit trees of the better kinds. In Apples Lord Suffield is taking the place of the old Keswick Codlin, and Blenheim Pippin, Dumelow's Seedling and fruits of this class are planted freely; whilst in Pears Louise Bonne of Jersey, Williams' Bon Chrétien, and the Beurrés are finding their way to the front. But this is getting away from the subject. I have been led to make digression simply to show that we have found that fruit can be grown in the county despite the prophesying to the contrary; and though we cannot boast the climate of Kent or the shelter of the valley of the Midlands, we are able to grow Codlins and Pippins when we set our minds upon it.

I find the fruit farm now under consideration consists of about thirteen

acres, the greater part of which has only been planted some few years, so that it is gradually improving, but its present possibilities are of the most satisfactory character. There are, I should say, four acres of Strawberries, and one may study the fruit to perfection, for there is plenty of variety. Here is Sir Joseph Paxton, always a market favourite. It is shapely, solid, and well flavoured, and if gathered in dry weather it may safely be allowed to stand a couple of days, not only without fear of injury, but with a chance of its improving in quality. In another "break" is Forman's Excelsior, perhaps the best fruit in the garden. It is not a very heavy cropper, but is pretty well flavoured and in every way commendable. President, Sir Harry, Amy Robsart, Oxonian, Keens' Seedling all have their quarters and their points of excellence, and beside these we find a quarter devoted to the cultivation of some American varieties, but the flavour is not quite equal to English kinds. We must not omit reference to a large bed of Moffat's Duke of Edinburgh, perhaps the best late dessert Strawberry in the garden. It certainly looks beautiful, and with true ducal grandeur H.R.H. here sets off the Strawberry leaves to advantage.

The Raspberries were a wonderful show, and there must have been tons of Gooseberries of all kinds running up between the rows. Currants in clusters, and Apples, Plums, and Pears everywhere. The Victoria Plum trees are so heavily laden with fruit that the boughs are broken. Of Denbigh Seedling there is an excellent crop, while some young pyramids of the Pershore Plum are making good promise. I can scarcely convey a proper idea of the crops borne by the Plums. Many of the trees have to be supported, and the drooping boughs are hidden by the clusters which crowd them.

The Apples are wonderfully fine. Many of the trees are quite young, and most of them have carried such a weight of fruit that they have had to be thinned to prevent disaster. The Worcester Pearmain gives its warmth of rosy colour in the lines, whilst Ecklinville, Mère de Ménage, Maltster, and other popular varieties hold important places in the collection.

There are more Pears than I could venture to calculate. In the old orchard long lines of Hesses and some of the older dessert varieties are prominent heavily laden. In the new garden Louise Bonne of Jersey, Jargonelle, Beurré Diel, Beurré d'Amanlis, and several trees of Fertility showing sufficient title to their name. Pears are grown here to perfection. Rightly gathered and carefully stored they are not surpassed for either size or quality by any I have seen from any English county. As a proof of their excellence I may mention that last year for the crop of Beurré d'Amanlis from this garden, 3d. per lb. wholesale was realised.

There is much more to see and say, for every department is thoroughly represented, but time flies, and there are limits to editorial patience. But one word about the house. Here there are facilities for storing and packing, and this is an essential feature which must not be overlooked. The absolute cleanliness of all arrangements connected with the packing gives a finishing grace which cannot be despised, however well the fruit may be grown. The farm I have described is situated in the Wirral division of the county, within reach of good market towns, and is upon the cold clay of the district, is not sheltered in any way, but is open to the sweeping winds from the coast, and yet the experience of every year adds its unmistakable weight of practical testimony to the fact that fruit of best quality, and in great quantity, can be successfully grown, and that just now no industry is more productive than a well managed fruit farm. It would be out of place here probably to give further details of the daily round of duty, but as I walked through the fields in the cool of the evening to catch the train at the nearest station, I thought there could be no more healthy or desirable occupation than that of dressing and keeping a garden, and I found that I had learned why Farrall's fruits have command of the market.—JOHN EDMUNDS.

CRYSTAL PALACE FRUIT SHOW.

SEPTEMBER 4TH AND 5TH.

THE annual Exhibition of fruits at the great and popular Sydenham Palace is always looked forward to by horticulturists as one of the leading events of the year, and the majority of the leading gardeners of the southern counties endeavour to obtain a place in the list of prizewinners. This season the credit and fame of the Show was most satisfactorily maintained, for it was generally pronounced to be one of the best "all-round shows" held for some years. There were necessarily some exhibits of greatly inferior merit, but the most striking feature was the general evenness of quality of the produce staged, which rendered the competition in all the chief classes very close. This is exactly what should be expected at such an important leading exhibition, and there is no doubt that the liberality of the Company in offering substantial prizes has contributed in a very large degree to the success which has attended their efforts to obtain a thoroughly representative fruit show. Much praise is also due to the Superintendent, Mr. W. G. Head, for the careful and methodical manner in which all the arrangements were conducted, for the judicious management of the innumerable details connected with an exhibition of this character is essential to insure satisfactory results.

Two long tables were devoted to the fruit in competition, the central lines between the collections being occupied with Palms, Ferns, and other plants that served to break the uniformity which would have otherwise prevailed. A fringe of baize or similar material along the edges of the tables would have been advantageous, as it would have concealed the boxes, baskets, and packages used by the exhibitors, and which were rather too noticeable. As regards the exhibits, there was a good proportion of the different kinds, but Grapes were especially well shown, and some magnificently finished examples of black Grapes were entered, Muscat of Alexandria being also admirably shown, particularly by Mr. Lowry, who deservedly gained the premier prize in a large class with that variety. Some good general collections of fruit were staged, and Peaches, Nectarines Plums

Apples, and Pears were all represented by numerous and praiseworthy samples.

COLLECTIONS.—The leading class in the schedule was provided for a collection of not less than twenty dishes, and in this there were six competitors, all showing well. Some little taste had been exercised in arranging several of these, sprays of *Ampelopsis Veitchii*, *Myrsiphyllum asparagoides*, and the common *Barberry* being placed between the dishes with very good effect, but in nearly every case Vine leaves were employed in the dishes for placing the fruit upon. Premier honours were after a careful consideration awarded to Mr. J. Roberts, gardener to Messrs. Rothschild, Gunnersbury Park, who exhibited some very fine fruits not only in this, but in other classes, and was one of the most successful of all the competitors. In the collection he had the following Grapes—Black Hamburg, very handsome; Alnwick Seedling, beautifully coloured; White Tokay, well ripened; and Muscat of Alexandria, good bunches of fine colour. Two handsome even fruits of Queen and Smooth Cayenne Pine Apples were included, together with Transparent Gages, Brown Turkey Figs, Red Astrachan Apples, William Tillery Melon, Morello Cherries, Sea Eagle and Nectarine Peaches, Victoria and Lord Napier Nectarines, Williams' Bon Chrétien Pears, Moorpark Apricots, Kirke's Plums, and Quatre Saisons Strawberries, all of which were distinguished by their good quality. Very closely followed Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, whose best dishes were Black Hamburg and Madresfield Court Grapes, both handsome bunches, and the latter superbly coloured; two large Charlotte Rothschild Pine Apples, Pond's Seedling Plum, McLaughlin's Gage, Garibaldi Strawberries, Meredith's and Bailey's Green Flesh Melons, Moorpark Apricots, Brown Turkey Figs, Mr. Gladstone Apples, with Peaches, Nectarines, &c. A few points behind was Mr. H. W. Ward, gardener to the Right Hon. the Earl of Radnor, Longford Castle, Salisbury, who was third with an even and highly creditable collection, comprising noteworthy examples of the following—Black Prince, Foster's Seedling, and Muscat of Alexandria Grapes, all well ripened; Queen and Smooth Cayenne Pine Apples, Brunswick Figs, Bellegarde Peaches, Hero of Lockinge Melon, Moorpark Apricots, Kirke's Plums, Green Gages, Morello Cherries, and Cox's Golden Gem Melon.

There were five competitors with collections of twelve dishes, first honours being obtained by Mr. Coomber, gardener to J. A. Rolls, Esq., The Hendre, Monmouth, with excellent fruits of the following varieties:—Muscat of Alexandria and Gros Maroc Grapes, both good, but the latter particularly well coloured; Royal George Peaches, Lord Napier Nectarines, Smooth Cayenne Pine Apple, La Grosse Sucrée Strawberries, Brunswick Figs, Reine Claude Violette Plum, Clapp's Favourite Pears, a large Melon, and some less important fruits. The second place was assigned to Mr. G. T. Miles, Wycombe Abbey Gardens, who also had some admirable fruits, his Grapes being especially fine. Three bunches of Muscat of Alexandria weighed 7 lbs., and three of Foster's Seedling 8½ lbs., both well finished. Other good exhibits were Jefferson Plums, Sea Eagle Peaches, Moor Park Apricots, Devonshire Quarenden Apples, Hero of Lockinge Melon, and Smooth Cayenne Pine Apple. Third honours were adjudged to Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton Court, Trowbridge, who showed very well, his strongest points being the Black Hamburg and Trebbiano Grapes, Downton Nectarine, and Best of All Melon.

A class was also provided for eight dishes, in which the competition was keen; Mr. Pratt, Longleat Gardens, Warminster, securing leading honours with Muscat of Alexandria Grapes, very large in bunch and berry and finely coloured. The Black Hamburg Grapes were also very fine, but had been slightly rubbed; Brunswick Figs, Windsor Pears, Pitmaston Orange Nectarines, Noblesse Peaches, Jefferson Plums, and a large Melon. Mr. Edmonds, Bestwood Lodge Gardens, Arnold, Notts, followed, showing Muscat of Alexandria and Alicante Grapes, very fine; Barrington Peaches, good; Violette Hâtive Nectarines, and Brown Turkey Figs. Mr. Elphinstone, gardener to E. M. Munday, Esq., Shipley Hall, Derby, was third with a praiseworthy collection, his Black Hamburg and Muscat of Alexandria Grapes being especially good, the Pine Apple Nectarines, Brown Turkey Figs, and Moor Park Apricots were also fine.

GRAPES.—An excellent display of Grapes was provided in the classes devoted to them, but the black Grapes were generally the best, with a few exceptions in favour of Muscat of Alexandria. The principal class was that for ten varieties; and though this is one that must necessarily be confined to comparatively few competitors, five exhibitors entered the list, and the contest for the first place was sufficiently close to render it very interesting. Mr. J. Roberts proved victorious with a fine even collection, every bunch being clean, well ripened, and, though not of unusual size, they afforded ample proofs of excellent culture. The varieties were Alnwick Seedling, of fine colour; Trebbiano, even, medium size bunches; Gros Maroc, very large berries of grand colour; Muscat of Alexandria, even bunches of medium size and fine colour; Black Hamburg, very large berries, handsomely coloured; Foster's Seedling, finely ripened; Madresfield Court, handsome colour, good bunches; Buckland Sweetwater, large berries, and good compact bunch; and Lady Downe's, medium size, and capital colour. Mr. H. W. Ward was adjudged second honours for well-coloured bunches of Black Hamburg, Alicante, Foster's Seedling, Gros Maroc, very fine; Muscat of Alexandria, Mrs. Pince, Buckland Sweetwater, Gros Guillaume, Syrian, and Black Prince. The third prize was obtained by Mr. J. Wallis, gardener to the Rev. W. Sneyd, Keele Hall, Newcastle, Staffs, whose varieties were Alicante, Alnwick Seedling, very fine; Foster's Seedling, Golden Queen, Gros Maroc, Gros Guillaume, Madresfield Court, Black Hamburg, Muscat of Alexandria, and Buckland Sweetwater.

Half a dozen exhibitors also entered with five varieties of Grapes, and this time Mr. Pratt took the lead with a very handsome collection of fine bunches of the following varieties:—Lady Downe's; Mrs. Pince, large bunches, and good colour; Black Hamburg, extremely large bunches; Muscat of Alexandria, grand bunches, and berries of fine colour; Alicante, medium berries, large bunches of fine colour. Mr. J. Hudson, gardener to H. J. Atkinson, Esq., M.P., Gunnersbury House, Acton, won second honours with Gros Maroc, Black Hamburg, Muscat of Alexandria, Madresfield Court, handsome bunches and berries; and Alnwick Seedling, neat bunches. Mr. A. Smith, gardener to W. H. Seville, Esq., Warren Hill, Loughton, Essex, was third, his best bunches being Gros Colman and Alicante.

Black Hamburg.—In several of the classes devoted to special varieties

competition was very keen, and it was particularly so in those for Black Hamburgs and Muscat of Alexandria, which keep the foremost place as useful Grapes. There were eleven exhibitors of Black Hamburg, and the majority of these were good examples both as regards size of bunch and finish. Mr. Pratt was first with extremely large bunches bearing a beautiful bloom, but the berries were not above medium size. Mr. J. Bury, Tewkesbury Lodge Gardens, Forest Hill, was second, also with large bunches and medium berries of good colour; Mr. F. Jordan, gardener to B. Foster, Esq., The Hill, Witley, Godalming, being third with smaller but capitally coloured bunches.

Muscat of Alexandria.—The same number of competitors entered in this as in the preceding class, but though the bunches were large they were, with the exception of the first, rather deficient in finish, and there was in two or three cases a too perceptible greenness that did not add to their beauty. Mr. J. J. Lowry, gardener to J. Macandrew, Esq., Belmont, Mill Hill, Hendon, was awarded first honours for three superb compact even bunches, large in berry, clean, and beautifully coloured. They were greatly admired, and Mr. Lowry deserves much credit for the production of such fine samples of this Grape. Mr. P. H. Edwards, gardener to D. P. Blaine, Esq., Fowley, Liphook, Hants, followed, also with large bunches, but not quite so well set or coloured; Mr. Pratt being third with fine bunches wanting in colour.

Gros Colman.—Only two entered with this variety. Mr. H. Dawes, gardener to the Hon. Mrs. Meynell Ingram, being first with handsome bunches and berries; and Mr. W. Elphinstone was third with small examples. It is probable that this class will be cut out another year in favour of one for Gros Maroc, which was so well represented in the general collections.

Madresfield Court.—This beautiful Grape was shown by four competitors but now its merits are becoming known we might almost expect a stronger contest; probably, however, many have not quite mastered its culture yet. Mr. Goodacre was first with even, compact, and handsomely coloured bunches. Mr. J. Hudson followed very closely, and Mr. H. Folkes, gardener to T. T. Halsey, Esq., Hemel Hempstead, was third with smaller bunches but fairly coloured.

Alicante.—Eleven entries of Alicante provided a keen competition, the majority of the exhibits being so nearly equal that there was little to judge between them as regards colour and finish. Mr. Howe, gardener to Henry Tait, Esq., Park Hill, Streatham Common, was first with three large bunches, weighing 16 lbs. Mr. Pratt was second: Mr. T. Osman, gardener to N. L. L. Baker, Esq., Ottershaw Park, Chertsey, was third; and an extra prize was awarded to Mr. Neighbour, Bickley Park.

Any other White variety.—In this and the following class there was the same number of entries as in that just noted. Mr. Osman took the lead with White Frontignan, three long fine even bunches, superbly coloured of a rich amber tint. Mr. H. Folkes, gardener to T. F. Halsey, Esq., Gaddesden Place, Hemel Hempstead, was second with Golden Queen, not very "golden" in colour, and Mr. J. Roberts was third with Buckland Sweetwater, with wonderfully large berries but not ripe. Other varieties well shown in this class were Trebbiano and Foster's Seedling.

Any other Black variety.—Three fine bunches of Gros Guillaume, weighing 21 lbs., gained Mr. Davies, of Temple Newsome, Leeds, the premier award in this class. Mr. Roberts was second with very handsome specimens of Gros Maroc, superbly coloured, and Messrs. Thomas Rivers & Son, Sawbridgeworth, were third with the same variety nearly as good. Other exhibitors had Alnwick Seedling, Lady Downe's, and "Cooper's Black," the latter bearing a dense blue bloom.

The competition was very close in the class for a basket of black Grapes, no less than ten entering, and the Judges had not an easy task to determine the relative positions of the exhibits. Ultimately, however, Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, was awarded the first prize for very handsome bunches of Black Hamburg, the berries of great size and beautifully coloured. Mr. C. Osman was placed second with Alicante, bearing a dense bloom; and Mr. Hudson was third with Alnwick Seedling and Madresfield Court, also good. There were only five exhibitors with a basket of white Grapes, Mr. Goldsmith, Kelsey Gardens, Beckenham, being first with Muscat of Alexandria, finely ripened; Mr. Pratt second with the same variety; and Mr. S. Castle, West Lynn, Norfolk, was third with Buckland Sweetwater, very large in bunch and berry.

MELONS.—In the two classes for scarlet and green flesh Melons there were respectively nineteen and fourteen entries, so that the Judges had a formidable task. In the scarlet variety class Mr. Bailey, Shardeoles, Amersham, was first with Victory of Bristol, followed by Mr. G. Boothroyd, gardener to H. Coleman, Esq., Woodville, Dover, with Scarlet Gem; and Mr. Gilman, gardener to the Earl of Shrewsbury and Talbot, Ingestre Hall, with a neat unnamed variety. The leading green flesh variety was Best of All, from Mr. R. Spinks, Victoria Road, Horley, Mr. Bailey being second with Golden Queen, and Mr. Ward third with Cox's Golden Gem.

PEACHES AND NECTARINES.—In the principal class for six varieties of Peaches and Nectarines there was only one exhibitor, Messrs. T. Rivers and Son, who had handsome fruits of the following varieties:—Peaches—Exquisite, Madeleine, Blanche, Bellegarde, Raymackers, English Galande, and Prince of Wales; Nectarines—Byron, Pine Apple, Oway, Newton, Orange, and Victoria. There were, however, six competitors with four dishes of Peaches, and five with the same number of Nectarines. Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., Ketton Hall, Stamford, took first honours with large handsome examples of Barrington, Prince of Wales, Princess of Wales, and Bellegarde. Mr. Goodacre was second with smaller but better coloured fruits, and Mr. Roberts was third. The last-named exhibitor was, however, first in the Nectarine class with excellent fruits of Victoria, Pitmaston Orange, Pine Apple, and Lord Napier. Messrs. Divers and Goodacre followed. The one-dish class brought thirteen competitors with Peaches and nine with Nectarines, the winners being as follows:—Peaches—Mr. A. Gibson, gardener to T. F. B. Atkins, Esq., Halstead Place, Sevenoaks, with Barrington, very fine. Mr. S. Pullman, Frampton Court Gardens, Dorchester, was second with Early Admirable, and Mr. G. Holliday, gardener to J. Norris, Esq., Castle Hill, Bletchingley, third with Violette Hâtive. The best Nectarines were Pine Apple from Mr. Pullman, Messrs. Evans and Divers following with the same variety, not quite so well coloured.

PLUMS.—As might be expected in such a good season as the present one the entries were numerous in the three classes devoted to Plums; but the fruits with a few exceptions were not unusually fine, and some were rather small. For four dishes of Red Plums, Mr. J. Neighbour was first amongst seven competitors with good fruits of Cooper's, Pond's Seedling, Cox's Emperor, and Victoria. Mr. Goodacre was second, his best varieties being Angelina Burdett, Pond's Seedling, and Victoria. Messrs. T. Rivers & Son followed, showing Belle de Louvain, Sultan, Prince of Wales, and Nectarine. There were nine exhibitors of Yellow and Green Plums, Mr. J. Wells, Fernhill, Winkfield, securing the leading place with Green Gage, Oullins Golden Gage (extremely fine), Jefferson, and Webster's Green Gage. Mr. Chadwick, Hanger Hill House, Ealing, was second, his best dish being Washington. Mr. Neighbour followed, showing Coe's Golden Drop, Washington, and white Magnum Bonum. Six collections of four dishes of Purple Plums were staged, Mr. G. Holliday, gardener to J. Norris, Esq., Bletchingley, leading with Purple Gage, Bradshaw, Quetsche, and Kirke's. Messrs. T. Rivers & Son took the second place with Belgian Purple, Grebé, Prince Englebert, and Reine Victoria; Mr. Goodacre, who was third, having fine fruits of Kirke's, Prince Englebert, and Old Orleans.

PEARS.—The display of Pears was not a large one, nor were the majority of the fruits of remarkable size; in fact, it was noticeable that the examples of many of the varieties were undersized. Still, there were fine fruits in some of the collections, and some of the best of these were from Mr. Butler, Orchard House Gardens, Sittingbourne, who has on previous occasions shown some handsome specimens from cordon-trained trees. He was first in the class for ten varieties, five fruits of each, with the following varieties, very fine:—Doyenné Boussoch, Beurré de l'Assomption, Conseiller du Cour, Pitmaston Duchess, Clapp's Favourite, Windsor, Beurré Hardy, Louise Bonne of Jersey, Williams' Bon Chrétien, and Beurré d'Amanlis. Messrs. Rivers & Son were second, their best fruits being Clapp's Favourite, Williams' Bon Chrétien, and Souvenir du Congrès. Mr. Waterman took the third place, having Gansel's Bergamot, Grosse Calebasse, and Williams' Bon Chrétien in good condition. With three dishes of Pears Mr. Butler was again first, showing Williams' Bon Chrétien, Windsor, and Desiré Cornelis. Mr. Waterman followed, his best fruits being Williams' Bon Chrétien; and Mr. Divers was third for Souvenir du Congrès, Pitmaston Duchess, and Clapp's Favourite.

APPLES.—In the general collections of fruits there were few good dishes of Apples, except the well known useful Devonshire Quarrenden and the Red Astrachan, but in the classes devoted to Apples there were some fine fruits of the leading culinary varieties. Mr. H. Waterman, who was first with twelve dishes, six dessert and six culinary varieties, had the following:—Lord Suffield, Gloria Mundi, Stirling Castle, Blenheim Pippin, Tower of Glamis, Warner's King, Worcester Pearmain, Red Astrachan, King of the Pippins, Gravenstein, Duchess's Favourite, and Devonshire Quarrenden. Messrs. T. Rivers & Son were awarded the second prize for fine examples of Lord Suffield, Hawthornden, Stirling Castle, Cellini, Worcester Pearmain, Duchess of Oldenburg, and Irish Peach. Mr. Layzell took the third prize with Blenheim Pippin, English Codlin, Alfriston, and Emperor Alexander amongst others. For three dishes of Apples Mr. Butler was first with Hunt's Early, Worcester Pearmain, and Red Astrachan, all finely coloured. Mr. Waterman followed, showing Devonshire Quarrenden, Astrachan, and Duchess of Oldenburg. Mr. Layzell being third.

MISCELLANEOUS.—A class was provided for a collection of fruit from fruiterers, in which the prizes were £12, £8, and £4. Mr. G. Wingfield, 37, Market Street, Brighton, was awarded the first prize for a very large and handsome collection of fine fruits, comprising all the best of those in season. Mr. G. Wood, 75, St. James Street, W., was third with a smaller but good collection. There were only two exhibitors of Pine Apples—namely, Mr. G. T. Miles and Mr. Goodacre, who were awarded the prizes in that order. There was also only one exhibitor of Figs, Mr. Wallis, who was awarded the first prize for Yellow Ischia and Osborn's Prolific.

With six dishes of Tomatoes Mr. C. J. Goldsmith was first with Stamfordian, Old Red, The Trophy, Acme, Reading Perfection, and Hathaway's Excelsior, all exceedingly fine even fruits. Mr. Goodacre secured the second place with Red Italian, Excelsior, Hackwood Park, Dedham Favourite, and Chiswick Red, nearly equal to the first in merit. Mr. S. Castle was third with Sutton's Conqueror, Chiswick Red, Old Red, Reading Perfection, Carters' Green Gage, and Dedham Favourite.

The non-competing exhibits comprised the following:—A large general collection of well-grown fruits from Mr. J. Neighbour, Bickley. Samples of the Dartmouth Crab, a pretty crimson fruit with a bloom like a Plum, from Mr. Laxton, Bedford. Mr. W. Salmon, 2, Ivy Cottage, Eldon Road, Lower Norwood, showed a twin fruit of Duke of Albany Cucumber. Mr. J. Butler, Orchard Lane Gardens, Sittingbourne, showed some beautiful fruits of Windsor and Clapp's Favourite Pears from cordon trees. Mr. James Don, 20, Chapel Row, Nottingham, sent tubers of a Potato called Village Blacksmith, a round variety with a rough brown skin.

GROUPS AND CUT FLOWERS.

One of the most prominent of the groups sent for competition was the magnificent collection of Tuberous Begonias from Messrs. J. Laing & Co., Forest Hill, which comprised a large number of their choicest single and double varieties arranged with Ferns, Isolepis, &c. Messrs. Kelway & Co., Langport, Somerset, had a grand collection of Gladioli spikes, representing some scores of their best varieties. Mr. Alexander Campbell, Gourcock, N.B., also had a superb collection of massive spikes of Gladioli, including some grand varieties. The Rev. H. H. D'Ombra, Westwell Vicarage, Ashford, had the best of the amateurs' collections of Gladioli, handsome spikes of good varieties. Three groups of early-flowering Chrysanthemums were shown, Mr. W. Piercy, Forest Hill, being first, followed by Mr. H. James and Mr. N. Davis, Camberwell. Hollyhocks, Asters, and miscellaneous cut flowers were also well represented by numerous exhibitors.

NATIONAL DAHLIA SHOW.

ANOTHER success was scored by the National Dahlia Society with its annual Exhibition on September 4th and 5th. It was held in conjunction with the Fruit Show above noted. There was plenty of competition in the majority of the classes, and the quality of the flowers was excellent—in fact, quite equal to that of former years. The general effect of the Show was

inferior to last year, owing to its being held in the central transept of the Palace, which dwarfs the Show by its magnitude. It has a compensating advantage, however, in allowing more room for the large number of visitors than is afforded by a marquee, and no doubt the management had this in view in holding the Exhibition in the Palace itself. Its popularity is evidenced by the immense number of persons who visited it both on Friday and Saturday. Appended are particulars of the awards.

NURSERYMEN'S CLASSES. Show Varieties.—Mr. Charles Turner, Royal Nurseries, Slough, was placed first in the principal class, that for forty-eight blooms, showing the following varieties:—Back row—Hon. Mrs. P. Wyndham, George Rawlings, Constancy, Imperial, Mrs. Kendal, Henry Walton, Prince Bismarck, Mrs. Foreman, Burgundy, Champion Rollo, J. N. Keynes, Georgina, William Rawlings, James Stephen, Mrs. Langtry, and Miss Cannell. Middle row—Sunbeam, Mrs. Gladstone, Hope, John Bennett, Mrs. Henshaw, Rosetta, Canary, Seraph, T. G. Saltmarsh, James Cocker, Clara, Joseph Ashby, Mrs. Hodgson, Lady Wimborne, Julia Wyatt, and Statesman. Front row—Ruby Gem, Mrs. Hodson, Chris. Ridley, Muriel, Mrs. Douglas, Mrs. S. Hibberd, Prince of Denmark, Lady Gladys Herbert, John Standish, Joseph B. Service, Senator, Mrs. Harris, Harry Turner, Mr. G. Harris, Goldfinder, and Joseph Green. The names are given in the order the blooms were placed. This was a splendid collection, the flowers being large and symmetrical, of good substance, and bright and clear in colour. They were in fact fully equal to those shown by this firm in former years. Second prize was deservedly awarded to Mr. William Boston, Manor Farm Nurseries, Carthorpe, Bedale. Some grand blooms were noticeable in this stand, and throughout they were of good size and shape; but they were not so fresh as those of the premier exhibitor, a circumstance which is no doubt mainly due to the long distance they had to be sent. The third prize was awarded to Messrs. Harkness & Sons, Grange Nursery, Bedale, who showed smaller but even blooms; and the fourth to Messrs. Keynes, Williams, & Co., Salisbury. Five stands were staged in this class. For twenty distinct varieties Messrs. Saltmarsh & Son, The Nurseries, Chelmsford, secured the premier prize with fresh medium-sized blooms of the following varieties:—Back row—Ethel Britton (a very fine bloom), J. Standish, Joseph Service, Hon. Mrs. P. Wyndham, Mrs. Dodds, James Cocker, Goldfinder, and Criterion. Middle row—Joseph Ashby, Lady G. Herbert, J. Lamont, Mrs. Gladstone (a beautiful flower), Shirley Hibberd, Constancy, Mrs. Harris, and Henry Walton. Front row—Mrs. Hodgson, Revival, Sunbeam, Mrs. Harris, J. N. Keynes, Hope, Earl of Beaconsfield, and Mrs. Shirley Hibberd. The second prize was adjudged to Messrs. Rawlings Brothers, Old Church, Romford, whose blooms were beautifully fresh and bright. Messrs. Paul & Son, Old Nurseries, Cheshunt, and Messrs. Cheal & Son, Lowfield Nurseries, Crawley, Sussex, were awarded third and fourth prizes respectively. One other collection was shown. Mr. J. Walker, 7 and 8, High Street, Thame, occupied the leading position in the class for twelve Show blooms. Good flowers of the following were shown:—Back row—Champion Rollo, William Rawlings, Mrs. Gladstone, and John Standish. Middle row—George Rawlings, Earl of Ravensworth, James Cocker, and Hon. Mrs. P. Wyndham. Front row—George Bennett, William Green, Mrs. J. Foreman, and Monarch. Messrs. James Gilbert & Son, St. Margaret's Nursery, Ipswich, who won the second prize, also showed well, good blooms of James Stephen, Hon. Mrs. P. Wyndham, and J. C. Quennell being noteworthy. Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, were placed third, and Mr. G. Humphries, Kingston Langley, Chippenham, fourth.

Fancy Varieties.—In this section the principal class was that for twenty-four blooms, and Mr. Turner was again to the fore, showing magnificently. Shapely blooms of good size, clean and fresh, were those from the Slough Nurseries. They were arranged as follows:—Back row—Rev. J. B. M. Camm, Annie Pritchard, Romeo (a splendid flower), Miss Annie Milsome, Hy. Glasscock, Fredk. Smith, Grand Sultan, and Gaiety. Middle row—Miss Browning, W. G. Head, Chas. Wyatt, Professor Fawcett, Duchess of Albany (very fine specimen), Peacock, Edward Peck, and Mrs. Saunders. Front row—Robert Burns, Jas. O'Brien, General Gordon, Miss Lily Large, Rebecca, Laura Haslam, Geo. Barnes, and Chorister. Messrs. Keynes, Williams & Co. were adjudged the second prize for smaller blooms, which, however, vied with the first-prize flowers for freshness and purity. Mr. Wm. Boston was placed third, his collection including several excellent blooms; and Mr. Hy. Clark, Rodley, near Leeds, secured the remaining prize. Messrs. Rawlings Bros. occupied the leading position with twelve blooms, good specimens of the following being represented:—Back row—Gaiety, Egyptian Prince, Lottie Eckford, and Peacock. Middle row—Frank Pearce, Polly Sandell, Professor Fawcett, and Mrs. Saunders. Front row—Mrs. Carter, Mrs. Steven, Annie, and Gem. Messrs. Saltmarsh & Son were placed second, Messrs. Cheal & Sons third, and Messrs. Paul & Son fourth, all showing well, the first named particularly so. Eight collections were staged in this class.

AMATEURS' CLASSES.

Show Varieties.—The principal class for amateurs brought ont several admirable collections. Mr. G. Boothroyde, gardener to Hy. Coleman, Esq., Woodville, Dover, being awarded the chief prize. He showed fresh symmetrical blooms of good size, the following varieties being staged:—Front row—Jas. Cocker, Harrison Weir, Geo. Rawlings, Clara, Hon. Mrs. P. Wyndham, Rev. J. Godday, Ethel Britton, and Prince Bismarck. Middle row—Miss Cannell, Lady Gladys Herbert, Vice President, Henry Walton, Mrs. G. Harris, Goldfinder, Earl of Beaconsfield, and Mrs. Gladstone. Front row—J. Standish, Miss Henshaw, Fredk. Rawlings, Mrs. Harris, John Bennett, Flag of Truce, J. Henshaw, and Mrs. Dodds. Mr. John Spoor, Prospect Cottage, Musgrave, Low Fell, Gateshead, staged some fine blooms, Seraph, Mrs. Gladstone, Clara, and James Vick being particularly good. He was awarded second prize. Mr. H. Glasscock, Rye Street, Bishops Stortford, was placed third, showing well; and Mr. J. Nation, Whitmore, Staplegrave, Tannton, fourth. Eight collections were shown. Mr. J. T. West, gardener to W. Keith, Esq., Cornwallis, Brentwood, was placed first for twelve blooms, good specimens of John Henshaw, Prince Bismarck, and Mrs. Gladstone being included in his stand. Mr. John Walker, Alum Well Road, Low Fell, Gateshead, was second; Mr. J. Tranter, Upper Assenden, Henley-on-Thames, third; and Mr. Thos. Garratt, Bishops Stortford, fourth. Ten collections were in competition in this class. Good blooms of Mrs. Harris, Emperor, Ethel Britton, Prince of Denmark, Goldfinder, and Mr. G. Har is

composed the first-prize stand of Mr. Jonathan Harris, Broomfield, Chelmsford, in the class for six specimens; Mr. Tunbridge, gardener to the Rev. — Trimer, Broomfield, Chelmsford, was awarded the second prize for six nice flowers, the third going to Mr. W. H. Aphorpe, Albion Brewery, Cambridge, and the fourth to Mr. Thos. Coote, North Terrace, Bishops Stortford. Eleven collections were staged.

Fancy Varieties.—Two classes were provided for these, and some exceedingly handsome collections were staged in each. Mr. Glasscock showed splendid blooms in the class for twelve varieties, and was adjudged first prize. Mr. Robert Petfield, Diddington, Hants, who was second, also showed well; Mr. Henry Vincent, gardener to John Hart, Esq., The Poplars, Keymer, being third; and Mr. B. Clark, Shottisham, Norfolk, fourth. Mr. W. Steer, 2 Hamilton Terrace, New Eltham, Kent, was to the fore with six Fancy varieties, showing well; Messrs. Boothroyde, Garratt, and West taking second, third, and fourth prizes in the order named.

The Turner Memorial prize, a handsome silver cup, was won by Mr. Glasscock. Unfortunately no one opposed him, much regret being expressed at the prize going without a struggle. This disappointment appeared to be experienced somewhat keenly by several cautious ones who had abstained from entering under the impression that the opposition would be overpoweringly strong. The conditions stated that twelve Show and six Fancy blooms were to be staged, and moderate specimens of the following were represented:—Show varieties (back row)—Geo. Rawlings, Miss Cannell, Imperial, and Hon. Mrs. P. Wyndham. Middle row—Mrs. Gladstone, Shirley Hibberd, Mrs. H. Glasscock, and Thomas Goodwin. Front row—Prince of Denmark, Cyprus, Senator, and Mrs. Harris. The Fancy varieties were H. Glasscock, Peacock, Professor Fawcett, Rev. J. B. M. Camm, Mrs. Carter, and Lottie Eckford.

OPEN CLASSES.—Classes were provided respectively for the best Show and the best Fancy blooms in the Show. The former was not difficult to find, a magnificent specimen of Mrs. Gladstone in Mr. J. Tranter's third prize collection of twelve readily securing the honour. It was a large and beautifully symmetrical flower, in fact we have never seen one more perfect. A specimen of this fine variety won similar honours last year. The best Fancy flower was a new and beautiful variety from Messrs. Rawlings Bros., named Frank Pearce, which is described amongst the certificated varieties.

Pompon Varieties.—Messrs. Keynes, Williams & Co. showed these increasingly popular kinds splendidly. Ten blooms of each variety were arranged in bunches with their own foliage, and they looked exceedingly pretty. The following varieties were represented in their first-prize collection of twenty-four. Back row—Lady Blanche, Darkness, Golden Gem, Rosetta, Flora Macdonald, Gem, Dora, and The Khedive. Middle row—Favourite, Mdle. F. Faconet, Isabel, E. F. Jungker, Little Prince, Catherine, Sappho, and Wilhelm Nitsche. Front row—Brunette, Little Bobby, Fanny Weiner, Nemesis, Mabel, Garnet, Cupid, and White Aster. Mr. Turner was a fair second, his flowers, though smaller, being fresh, and Messrs. Rawlings Bros. took the third prize. Messrs. Jas. Gilbert & Son secured the premier prize in the class for twelve varieties. They showed the following. Back row—H. Milesky, Guiding Star, Gem, Lady Blanche, Little Mabel, and Handelsgartner. Front row—Sensation, Little Bobby, Pure Love, J. E. O. Enke, Garnet, and Cupid. These were very prettily arranged. Messrs. Paul & Son were a very good second, and Messrs. F. T. Smith & Co., West Dulwich, third. The corresponding class for six varieties saw Messrs. J. Burrell & Co. to the fore with the following—Gem, White Aster, Coquette, Titania, Prince of Liliputians, and Little Duchess, all of which were well represented. Mr. West took the second prize, Mr. J. Walker the third, and Mr. G. Humphries the fourth.

Single Varieties.—These were particularly good, there being plenty of competition in the two classes provided for them. Four collections were staged; in that for twelve varieties the premier prize was awarded to Messrs. Cheal & Sons for the following:—Back row—Silver King, Queen of Singles, Chas. Laws, and Juno. Middle row—Negress, Alba Perfecta, Brutus, and Fashion. Front row—Henry Irving, Formosa, Sunset, and Paragon. These flowers were also arranged in bunches of ten, and were of very large size and good substance. A very fine stand from Mr. Turner secured the second prize, and third and fourth places were occupied respectively by Messrs. Keynes, Williams & Co., and Mr. Walker, Thame.

Messrs. J. Gilbert & Son were to the fore in the class for six sorts, taking first prize with the following, which were admirably shown—Lucy Ireland, Dr. Moffatt, Charles Laws, Mrs. Castle, White Queen, and Mrs. Bowman. Messrs. J. Burrell & Co. were a good second; Mr. W. Jones, gardener to J. S. Pope, Esq., Cedar Lodge, Bath, third; and Mr. Fred Hooper, Vine Nursery, Widcombe Hill, Bath, fourth.

The following novelties received first-class certificates:—

Pelican (Keynes).—Fancy; white ground, flaked with mauve; a large substantial flower.

Bird of Passage (Rawlings).—Show; white, tipped with pink; a medium-sized, shapely flower.

Frank Pearce (Rawlings).—Fancy; pale crimson streaked with maroon; of good substance and fine form.

Mrs. John Walker (Rawlings).—Show; white or blush tinged with purple; a medium-sized bloom.

Mr. Glasscock (Rawlings).—Show; rich crimson, very large and symmetrical; a good addition to the reds.

Mrs. G. Rawlings (Rawlings).—Show; white or blush, tipped with rosy crimson; a medium-sized flower of good form.

A large and attractive collection of Dahlias from Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, formed a notable feature of the miscellaneous exhibits. Messrs. H. Cannell & Sons, The Home for Flowers, Swanley, also exhibited a splendid group of Dahlias and Begonias. The collection was large and admirably arranged.

GATHERING APPLES AND PEARS.

SEPTEMBER and October are busy months in this respect where the fruit trees are numerous and the crops good. There will be few excessive crops to harvest this year, but average ones of both Apples and Pears are common. Many varieties are almost matured now, and others will continue to become so for the next six weeks or more. As a rule, when

gathering the fruit from a tree the whole crop is taken, never staying to consider whether the fruits are all ripe or not. In the case of Peaches, Plums, Apricots, &c., we always find that some fruits ripen days and sometimes weeks before others on the same tree; and so it is with Apples and Pears; and to secure these, more especially the best kinds, in proper condition, they should be gathered at different times as they become ripe, and not all together, as is too often the case. As a rule the largest fruits and that most exposed to the sun ripens first, and this should be collected before any which may be unripe on the shady side or centre of the tree. Keswick Codlins and some other early varieties which will not keep long need not have this rule applied to them very rigidly; but good and long-keeping sorts, and especially those for dessert, should have the utmost attention in this respect. It is an easy matter to collect the fruit from small dwarf trees, as no steps or ladders are required, nor shaking the branches, which is a great advantage, as it is often a difficult matter to place a heavy ladder against a large tree without knocking off a quantity of the fruit, ripe and unripe. Light ladders only should be used for this work, and the utmost care should be taken in handling them. There should never be any attempt at shaking the fruit from the branches unless it is to be used for cider-making. No fruit will keep well which is in any way bruised, and all which are injured should be put to one side for immediate use. The more valuable the fruit is, and the more perfect it is desired to keep it, the more careful must the specimens be handled. Some varieties we put into large hampers and carry them to the fruit room, but others are placed in a single layer on hay in a tray or basket. Very ripe and valuable Pears should all be collected in this way. It is hardly necessary to say that the fruit must be perfectly dry when taken in, and when many are ripening fast they should be examined every alternate day, or twice weekly, to secure the fruit before it falls. When stored at first much ventilation may be provided until the fruit and atmosphere are quite dry, then the closer they can be kept the better.—A KITCHEN GARDENER.

We are informed by Mr. Cutler, Secretary to the Gardeners' Royal Benevolent Institution, that a LEGACY OF £100, free of duty, has been left to the Institution by the late J. S. Law, Esq., of South Lodge, Enfield. This is an example which many more who have the means would do well to imitate.

— A MEETING of the General Committee of the NATIONAL CHRYS-ANTHEMUM SOCIETY was held on Monday last, at the Old Four Swans, Bishopsgate Street Within, at 7.30 p.m., by the President of the Society (E. Sanderson, Esq.), R. Ballantine, Esq., occupying the vice-chair. Mr. Holmes announced the death of one of the Society's judges (Mr. Charles Turner of Slough), and Mr. Ballantine proposed that, as this was the first assembling of the Committee since that event had occurred, that a vote of condolence with the family of Mr. Turner be passed, which was seconded by Mr. Kendall, and passed unanimously. It was announced that the Veitch Memorial medal and a cheque for the £5 accompanying it had been received. This handsome prize, it will be remembered, is to be offered for competition in Class 12 of the Society's schedule. The nomination and election of new members then followed. Mr. Holmes next took the opportunity of acquainting the meeting that application had been made by the different affiliated societies for sixteen of the N. C. S. medals, and it was resolved that he be authorised to have them struck. A model of the intended medal was submitted for inspection.

— A LINCOLNSHIRE correspondent writes as follows respecting THE WEATHER AND CROPS IN THE NORTH—"There has been no such exhausting drought here as in the south. The trees, hedges and fields are refreshingly green, like spring. Fields of Turnips full and luxuriant, and Potatoes looking as well as can be desired. The grain crops are mostly cut but still in the fields. They are very good. Fine weather is wanted for storing them. We have had a drenching rain to-day, and the weather has been more or less showery for a week past; indeed it has been so all the season, or vegetation could not be so luxuriant. Vegetables plentiful. Fine Onions 6d. per stone. Apples abundant, and selling at the same price. Plums 1d. per lb. It is like a land of plenty compared with the scorched fields and dried-up gardens in the south."

— THE SIXTH ANNUAL CRYPTOGAMIC AND BOTANICAL MEETING OF THE ESSEX FIELD CLUB will be held on Friday and Saturday, the 2nd and 3rd of October, 1885, in Epping Forest. It is intended to devote

the Friday to the collecting of specimens, and to their examination and arrangement by the experts, and on the Saturday to hold an Exhibition of fresh and preserved botanical specimens, microscopical objects, drawings, &c. The Exhibition will be mainly confined to subjects from the vegetable kingdom, but not necessarily to the Cryptogamia, although that division will hold a very important place. The Exhibition will be opened at four o'clock on Saturday, October 3rd, in the large ballroom attached to the Roebuck Inn, Buckhurst Hill. Ample time will thus be afforded for its careful examination by the visitors present, and all possible facilities will be given to exhibitors. The arrangement of the mycological specimens will, as usual, be under the control of Dr. M. C. Cooke, Mr. Worthington Smith, Mr. Warton, and other well-known fungologists. The management of the microscopical department will be in the hands of Mr. Frederick Oxley, F.R.M.S., and others.

— "C. R." writes—"OMPHALODES LUCILÆ does fairly well here planted between large pieces of limestone. As to slugs, I have tried what is, so far, a certain preventive. It consists of a collar of sheet zinc bound near the top by a ring of copper wire. It should then be pressed into the soil so as to leave no entrance for the slugs."

— In the COLLECTION OF GLADIOLI AT THE CRYSTAL PALACE from Mr. Alex. E. Campbell, Cove Gardens, Gourock, N.B., were many handsome varieties, which being especially well grown showed their characters most effectively. A few of the best are the following, which are selected chiefly for the distinctness of the shades and the massiveness of the spikes—Adolphe Brongniart, rose tinted orange; Amalthea, white tinted violet; Archduchess Maria Christina, white tinted lilac; Belladonna, white shaded with lilac and carmine; De Mirbel, rose, very handsome; Dido, white with a lilac tint; Horace Vernet, brilliant red, very bright and showy; Ida, white with a carmine shade; Marie Dumortier, white streaked with rose; Marquis of Lothian, rich rose colour; Ondine, white violet spots; Princess Mary of Cambridge, white with carmine spot; and Rossina, rosy red, white spots.

— MR. J. MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, AUGUST, 1885.—Mean temperature of month, 56.0°. Maximum on the 16th, 74.8°; minimum on the 15th, 36.3°. Maximum in the sun on the 6th, 128.8°; minimum on the grass on the 15th, 29.0°. Mean temperature of air at 9 A.M., 56.8. Mean temperature of soil 1 foot deep, 58.3°. Warmest day the 10th; coldest day the 27th. Total duration of sunshine in the month, ninety-four hours, or 21 per cent. of possible. We had eight sunless days. Total rainfall, 2.58 inches. Rain fell on ten days. Average velocity of wind, 8.4 miles per hour; exceeded 400 miles on two days; fell short of 100 on six days. Temperature, both mean and extreme have been considerably lower than in any of the previous nine years. Sunshine, less than in any of the last four years, and not half as much as last year. Rainfall about the average. Number of rainy days small. Sunshine much needed for fruit and fruit trees.

— A GIGANTIC CLIMBER.—BAUHINIA VAHLII, the stem of which sometimes attains a circumference of 5 feet (!) is thus noticed in the proceedings of the Horticultural Society of India. From Captain Pogson, enclosing a letter to him from Mr. Smythies, Deputy Conservator of Forests, Dehra Doon, and forwarding a parcel of Bauhinia Vahlia seeds. Mr. Smythies says, "This is one of the commonest climbers in India, and has a wide range. I should be glad if the natives would eat the seeds, pluck all the leaves, and cut down all the stems of this climber in our forests. We wage war against it, and have already cleared a considerable tract in Rangrah of this weed. The stem is sometimes 5 feet in girth, and the leaves range up to 18 inches in diameter. We annually grant a large sum for the destruction of this climber, and eventually shall exterminate it; but it will be a work of time. In the open forests, I am afraid, it will remain for ever."

— THE ANNUAL DUNDEE FLOWER SHOW, under the auspices of the Dundee Horticultural Society, was opened in the Drill Hall last Thursday. The season having been favourable, there was a magnificent display in every department; and the general opinion that the Show was one of the best ever held by the Society was amply confirmed by the Judges, who unanimously declared the Exhibition to be superior to that of any provincial town. There were 220 competitors, and the entries numbered 1906, classified thus:—Plants, 222; cut flowers, 487; fruit, 405; vegetables, 656; and honey, 136. Though the weather was showery there was a large attendance of visitors during the day, and in the evening the hall

was crowded. A sum of £51 was taken at the gates. The Show remained open till Saturday night.

— THE groups of EARLY-FLOWERING CHRYSANTHEMUMS AT THE CRYSTAL PALACE SHOW last week, though not arranged to the best advantage, included some very pretty varieties which are particularly useful at this time of year. The white Mrs. Cullingford, the yellow Flora, the purple La Bien Aimée, together with Early Blush, nanum, and G. Wermig, were noticeable varieties. The best of all, however, was the floriferous Madame Desgranges, of which some very beautiful plants were shown, one from Mr. G. Christmas being uncommonly good in habit and number of blooms. By the exercise of a little taste some attractive groups could have been arranged, but very little was shown by any of the exhibitors.

— At the Sydenham Show last week Mr. W. E. Bennett, Condoover, Shrewsbury, exhibited the SIMPLESS FLOWER POT CLEANSER, which attracted much attention from the gardeners present. It is a simple machine in the form of a tank, with two cylindrical brushes of different length side by side, which are turned by a handle, quickly and effectively cleansing the inside and outside surfaces of a pot at the same time. By the assistance of this cleanser, which is easily managed, pots of any size can be rapidly and thoroughly washed, a matter which is often of considerable importance in gardens when other work is pressing and labour is limited.

— IN preparation for the NATIONAL PEAR CONFERENCE, to be held at Chiswick in October this year, cards are being issued with spaces for giving the name, season, average fertility, stock, and general description. These are intended to be used by exhibitors for each separate dish or variety submitted. Exhibitors will be requested to fill in the required particulars wherever it is possible to do so. Where the name of the variety or the stock may be unknown the space may be left blank. The cards being numbered, exhibitors should, in packing their fruit, use a corresponding number with each variety. At the close of the Exhibition these cards will be collected and retained by the Committee for future reference. A form to be filled up by exhibitors has also been prepared, which are intended to give the following information:—Exhibitor's name and address. Number of varieties exhibited. Situation where grown, sheltered or otherwise, aspect, &c. Character of soil, subsoil, &c. Selection of varieties most suited to district, arranged for the following seasons—viz., July and August, three varieties; September, three varieties; October, six varieties; November, six varieties; December, six varieties; January to March, six varieties. Selection of varieties suited for orchard cultivation, not exceeding twelve. Selection of stewing Pears, four varieties. General remarks, as to modes of cultivation, pruning, stocks, &c. By means of these forms, which can be had on application to Mr. A. F. Barron, it is hoped that a great amount of useful information will be obtained for subsequent classification.

PINKS FOR FORCING.

ALL who desire a good supply of sweet fragrant white flowers in succession during the spring months should establish in from 3 to 6-inch pots a quantity of the common white garden variety and Mrs. Sinkins. If a coloured variety is also appreciated Ascot may be used, for it strikes root freely, flowers profusely, and is a good grower. The sooner these are well established the earlier they can be forced into flower, and if cuttings are inserted or plants potted now they will be well established before winter. The plants for 3 and 4-inch pots should be raised by inserting six or eight cuttings in each pot, which will soon strike root in moderately sandy soil if well watered, kept close and shaded in a cold frame for about a fortnight. The cuttings root best when taken off with a portion of the old wood attached. The plants for 5 and 6-inch pots should be lifted from the borders, and if small pieces were planted out last autumn or spring for this purpose they will be large enough and may be potted without division. If plants of a suitable size do not exist large clumps may be lifted, divided, and potted, placing a little sand about their stems, from which they will soon commence to form fresh roots. Those lifted with a good quantity of active roots and carefully placed in pots may be stood in a shady position outside until they have commenced to root afresh, when they should occupy an open sunny position. The divided plants containing few if any fibry roots should, if possible, be kept close and shaded in a cold frame until root activity has commenced. When lifted at this season of the year the plants very soon establish themselves

and are better in a suitable outside position than kept in frames. These plants start better and more quickly into growth after they have been subjected to one or two good sharp frosts than is the case if protected from early frosts by a frame.

If plants suitable for decoration in pots are not desired and the flowers only wanted in a cut state, it is not worth going to the trouble of establishing them in pots, for they do wonderfully well when good clumps are lifted and placed in boxes. The most suitable boxes for these are those about 18 inches in length, 9 inches wide, and not less than 4 inches deep. These will each accommodate four or five good plants, and more if they are only of a small size. The treatment after placing them in boxes should be the same as advised for those to be grown in pots, which entirely depends upon the quantity of fibry roots the plants possess when lifted. Those grown for this purpose in boxes need no farther staking than placing two or three short stakes round the sides of the box, one or two rows of thin matting being placed round to keep the outer flower stems from falling about. Those grown in pots for room and conservatory decoration have each flower stem supported with a slender portion of cane.

For the benefit of those that have not forced these plants it may be added that they must not be into flower in a close confined atmosphere, or they will become weakly and produce only poor flowers, if any. The earliest should be started in December on a shelf close to the glass where the night temperature ranges from 45° to 50° until they commence growing, when a few degrees higher than the last-named temperature may be maintained until they come into flower, providing a circulation of air is daily admitted to the plants when the weather will allow of such being done. I have always found a shelf in an early vinery or Peach house just started to work an admirable position for them until they are lengthening out their flower stems, by which time the atmosphere of the vinery is often too confined for them. The plants should then be removed to a cooler and more airy position. Very often those grown in boxes are not removed from these positions until the flowers have been cut, for they are no worse for cutting even if the flower stems are slightly drawn, which would totally destroy the beauty of those grown for decoration in pots.—W. D.

HIMALAYAN WINDFLOWERS.

OF the Windflowers inhabiting the Himalayan Mountains, numbering about fifteen altogether, probably not more than half a dozen are in cultivation at the present time, and that notwithstanding the large amount of seeds of various kinds imported annually from these localities. Those already introduced are much admired, and especially those with such a wealth of foliage and bold appearance as in the present instance. The wonder is that more attention is not given to collecting seeds of the others, many of which are said to far surpass those already introduced as useful garden plants. Those annually received from the south of France, &c., and which belong to the *Anemone* group, seldom if ever give satisfaction to the grower unless on the very lightest and sandiest soils or in a particularly favourable situation. Where the locality is damp and the soil clayey, success is almost impossible, and even if they grow they must be lifted when they have flowered, submitted to a process of roasting, stored away for a time, and then replanted, all of which entails a large amount of labour, the more so if grown in quantity, hardly to be tolerated in the average garden, especially at so busy a season of the year. Some of the Himalayan species not yet introduced are just as brightly coloured as the European sorts, besides having the advantage of being perfectly hardy in all situations; indeed, the situations worst suited to *A. coronaria*, *A. fulgens*, &c., are just the places in which the others thrive best; the cooler and more shady, provided the drainage be good, the better will they grow and flower.

A handsome plant is *A. polyanthes*, of which a good illustration is given in fig. 39, and which has been generally distributed under the name *A. obtusiloba*; that differing, however, from *A. polyanthes* in having oblong unwinged fruit, fewer-flowered scapes, and having purplish or golden instead of white flowers. *A. polyanthes* grows about a foot to 18 inches in height, with a wealth of fine ornamental foliage not equalled by any we know. The flowers are produced in bunches of from six to eighteen, umbel fashion, on longish scapes. The flowers are rarely less than an inch in diameter, pure white, firm-textured, and lasting a considerable time in a cut state. It loves shade, plenty of moisture in rather a heavy but rich soil. The leaves are deciduous; the crown, though exposed, requiring no protection, as it is found at altitudes of from 10,000 to 12,000 feet above sea level from Kashmir to Sikkim, flowering during the early

summer months. It is nearly allied to the better known *A. narcissiflora*, and is thought to be connected with that species by *intermedialis* (syn. *A. longiscapa*, Wall.; *Scaposa*, Edg.; *villosa*, and *Govaniana* Royle). The others in cultivation are *A. vitifolia*, *A. rivularis*, and *A. narcissiflora*, &c.—M. S.

TOMATOES IN AUTUMN.

SPEAKING from experience and extensive observation, Tomatoes have often succeeded better out of doors than they have done this season. The plants did not start so freely into growth after being turned out as they ought to have done, and this retarded their fruiting until later than usual. I know of several instances where they were bearing ripe fruit against the open wall in July last year, and plants in the same position have hardly as yet a ripe fruit on them. A good start is everything in outdoor Tomato-growing, because as soon as the plants become robust and established thoroughly, they will fruit, whether the summer and autumn are favourable or not. Open-air plants, if properly managed, will yet produce much fine fruit, and more attention should now be devoted to getting the fruit ripe that is formed than in trying to secure more fruit. Any which may form now and after this time will never mature or become large enough to cut and ripen indoors in October, and the best treatment open-air plants can have now is to stop all young growths, allow no more blooms to form or open, and thin the leaves off which are shading the fruit. Ripen what is on them, but do not try for any more. As soon as fruits of fair size begin to change colour, cut them off and put them in a greenhouse or room to finish ripening. It would not increase in size much if left on, and it will colour and be as well flavoured if ripened as we suggest as it would be on the plants, so long as they are not cut until colouring commences. When they are watered at the roots liquid manure may be given them, but it is better not to give much as the days shorten, for the fruit will swell almost as well and not be so liable to decay prematurely if the plants are kept rather dry at the roots.

When there is much rain it may be difficult to observe this rule, but in that case we would place some spare frame lights over the plants to afford shelter and hasten the ripening of the fruits. Last autumn we had ripe Tomatoes in the open until the middle of November through putting lights against the wall and over the plants.

Where Tomatoes are wanted very early in the spring, the best way to secure plants for the purpose is to take cuttings during September, root them in 3-inch pots, keep them in these until the new year, and then give them more heat and root room, when they will start rapidly into growth and bear ripe fruit sooner than any plants which can be raised from seed in the spring. If many varieties have been grown this season, and one has proved superior to all the rest, it might not do to save seed of it with the hope of still having it true, as they sometimes degenerate a little by being crossed with others, but if stock cuttings are taken in autumn the genuine sort will be secured beyond doubt.—A KITCHEN GARDENER.

BATH FLORAL FETE.

SEPTEMBER 2ND AND 3RD.

ONE of the finest exhibitions of the year, as the Show in question undoubtedly was, opened under somewhat depressing circumstances, rain falling more or less heavily throughout the first day, and towards evening it descended in torrents. The Mayor of the city, however, in the course of his eloquent speech at the luncheon, remarked as an expression of consolation, that what was a misfortune to them was a blessing to others. Yet though it was not possible to suppress feelings of disappointment that such a splendid Exhibition could not be enjoyed by the thousands of persons who were longing to see it, there was no despondency, the Committee appearing to take cheerful refuge in the hope of "a brighter day to-morrow."

It were almost impossible to imagine a more suitable position for a show than Sydney Gardens, Bath, which are extensive, pleasantly undulated, and abound in fine trees. So plentiful are these, that the marquees in which the products are arranged are quite masked, the system being adopted of isolating them in different parts of the grounds. When the weather is fine a brilliant company invariably assembles, promenading the embowered walks and admiring the plants, fruit, flowers, and vegetables as the different tents are reached, while, at the same time, the crowd is divided in the most agreeable manner. The show in question was the largest ever held, splendid examples of culture being arranged in every department.

PLANTS.—The long marquee, which covers a series of grass terraces on which the specimens are arranged, presented a beautiful appearance, magnificent *Fuchsias* (such as are only seen in the west of England) alternating with grand stove and greenhouse plants from Mr. Cypher and other exhibitors. The *Fuchsias* were accorded the post of honour in the schedule, the first five classes being devoted to them. In the class for nine plants the prizes were £6, £4, and £2, and they were won respectively by Mr. Snell, gardener to Mrs. Counsell; Mr. Lye, gardener to the Hon. Mrs. Hay; and Mr. Tucker, gardener to Major W. P. Clarke. The first-prize plants were characterised by a free gracefulness in training, fine foliage, and large flowers. They were 7 to 8 feet in height and 4 to 5 feet in diameter across the base. Mr. Lye's plants were close columns 9 to 10 feet high, about 2 feet in diameter at the base, and terminating in a point like a church spire. They were perfectly furnished, and every inch covered with flowers, and apart from the "close lacing" were less vigorous than the others. Mr. Tucker's plants were still taller but rather less full and vigorous. The last-named exhibitor secured the first prize in both the light and dark single specimen class with *Charming* (dark) and *Arabella* (light) 9 to 10 feet high, Mr. Lye following with smaller but admirably grown specimens. Mr. Hall, gardener to C. H. May, Esq., was first with six plants; Mr. Sonthard, gardener to F. J. Walker, Esq., second; and Mr.

Riddick, gardener to Mrs. Pinder, third; and for four plants the prizes fell to Messrs. Wilcox, Hawkins, and Drummond. The best plants in these classes were splendidly grown and trained, and the worst far superior to the best that are seen at metropolitan and the great majority of provincial shows.

fine bold freely branching variety; Acme, Load-me-well, Charming, bold and graceful; Elegance, Hon. Mrs. Hay, and Final, both very fine—in fact, all were highly effective. *Lights*: Marginata, Mrs. Bright, Lettie Lye, Harriet Lye, Emily Lye, Mrs. Rundle, and Arabella. Mr. Lye was awarded a certificate for some beautiful seedlings not yet named. The plants are

Fig. 39.—ANEMONE POLYANTHES.

In the production of such striking examples of culture as were exhibited in every class, the first consideration is selecting strong-growing yet free-flowering varieties. There are numbers of Fuchsias with the most beautiful flowers individually that are not suitable for large specimens. The most prominent varieties in the several classes were—*Darks*: Doel's Favourite, a

ripened, pruned, started under glass, and stood in the open air in June, hence their sturdy growth and floriferous nature; and cultivators who produce such plants as those referred to deserve all they win.

In the class for nine stove and greenhouse plants Mr. Cypher won chief honours with specimens that have never been excelled in September—

Allamandas, Stephanotis, Lapageria alba, and Ericas being delightfully fresh. Mr. Long, gardener to C. Gardiner, Esq., was an admirable second, and too much praise can hardly be accorded to the grower for producing such specimens in what we believe is a very small garden. Anthrums Andreanum and Schertzerianum were both fine; Ixoras and Rondeletias bright and good. Mr. J. Mould was placed third, staging Erica Marnockiana in superb condition, E. insignis being also fine, and Dipladenias very good. We understand the Judges desired to give an extra prize in this class, but the rain put a stop to all such awards. Mr. Hale well won the first prize in the class for six plants with admirably grown examples of Allamanda Hendersoni, A. nobilis, Ixoras floribunda nana and Fraseri, a finely coloured Bougainvillea, and a good Clerodendron. There was no prize card on the second collection. Mr. Tucker was third. Mr. James, gardener to General Doherty, were prizetakers in another class, the former staging a charming example of Dipladenia boliviensis, and the latter the good old Cassia corymbosa. Mr. Cypher staged the best single specimen stove plant, a splendid globe studded with rich golden flowers of Allamanda grandiflora, Mr. Long following closely with Ixora Williamsi. The best specimen greenhouse plant was Mr. Cypher's Phœnocomma prolifera Barnesi, and the best stove plant Cycas circinalis from the same exhibitor, who was also pre-eminent with twelve fine-foliaged plants—a grand collection in which Croton Sunset was magnificent. Mr. Tudgey was second, and Mr. Mould third. For six plants the prizes went to Messrs. Hall and Drummond respectively. Only two collections of Orchids were staged, Mr. Cypher being in his usual position with Saccolabium Blumei majus with six racemes, Cyrtopodium Parishii, Odontoglossum grande, Aerides Rohaniana, Oncidium Gardnerianum, and Cattleya Eldorado. Mr. Drummond followed, his best plant being Cattleya Gaskelliana. The prize for the best new or rare plant was awarded to Mr. Cypher for Aerides Lawrencei, a splendid variety, with very large richly tipped flowers.

Ferns were staged in first-rate condition by Messrs. Tucker, J. Mould, and Cake, who were awarded the prizes respectively for fifteen exotic varieties, Mr. Hall securing the chief prize for Britishers. Ericas were fresh and neat, Mr. Cypher winning the first prize with the following six:—Shannoni, æmula, McNabiana, insignis, Irbyana, and Kingstoniensis; Mr. Mould having the first prize for a single specimen with E. Hartnelli, very rich. Single Petunias were trained on flat-faced oval-shaped trellises, 2 feet by 18 inches, leaned back like a mirror; no prize cards attached. Double varieties were very dwarf, not more than a foot high, the plants bearing from twelve to twenty good blooms. Mr. Durbin, gardener to S. Needwell, Esq., being the most successful exhibitor. Tuberous Begonias were small, yet well grown, and will probably be finer next year. The prizetakers were Messrs. Clifford, Heard, and Lye. Verbenas were trained similarly to single Petunias, and had a pretty effect, Messrs. Mattock and Southard being the successful growers. Cockscombs were excellent, with stems from 6 to 8 inches high, with large foliage and handsome heads, but we failed to obtain the name of the grower. Mr. Walters, Bath, staged very good Gloxinias; Mr. Jones, Achimenes; Mr. Truckle, Balsams; and Messrs. Riddick, Jones, and Tucker Zonal Pelargoniums; dwarf, mushroom-shaped specimens, 3 feet in diameter, as fresh and as bright as could be imagined.

CUT FLOWERS.—It is very rare indeed that such Gladioli are seen as the thirty-six spikes with which S. Dobree, Esq., won the first prize. The spikes were broad and massive, and the colours clear and rich. The collection was in all respects remarkable for its great excellence. Mr. W. Brookes followed with very creditable examples of culture; the prizes for twelve spikes going to Messrs. Mattock, Tottle, and Walters. Dahlias were numerous and fine, not a few blooms being of the first order of merit. Mr. W. P. Shaw was the leading exhibitor, and his winning stand of twenty-four blooms would not be easy to surpass, Messrs. Nobbs and Harris following rather closely. Messrs. Tottle, Humphries, and Horsell were awarded the prizes for twelve Show blooms, and Messrs. Shaw, Humphries, and Smith were successful with Fancies. Beautiful stands of single Dahlias were exhibited by Messrs. Walkers, Cooling, and Tuckle, who won the prizes. Mr. T. S. Ware show a fine assortment not for competition.

Many very good boxes of Roses were staged. In the class for twenty-four triplets S. H. Budd, Esq., was the premier exhibitor with beautifully fresh and full Teas and Hybrid Perpetuals. Mr. Cooling was a close second, and Mr. Ralph Crossling third. For twelve triplets the awards fell to Messrs. W. Smith, F. Harris, and J. S. Burges; and for twelve singles Messrs. S. P. Budd, A. R. Farmer, and T. Hobbs were successful. Mr. G. Cooling staged a box of Rosa rugosa, flowers and fruit being effectively associated; also a stand of William Allen Richardson, not for competition. Fine bunches of Zonal Pelargoniums were staged by Messrs. Mattock, Cooling, and Hall, who secured the prizes in the class; Messrs. Pearson & Son, Nottingham, exhibiting varieties of conspicuous merit not for competition. Messrs. James, W. B. Carter, Walters, and Pope were among the successful exhibitors of Asters, which were numerous and good. Hollyhocks, Phloxes, and Verbenas were also exhibited. Messrs. Pethrick, Tagart, and Drummond were awarded the prizes for twenty-four bunches of flowers, and Mr. Cypher closed with first prizes for a bouquet and table ornament—making eleven first prizes in the same number of classes, and in the Show to which he contributed so well.

FRUIT.

A fairly liberal amount in prize money was offered for all kinds of fruit in season, and, as was generally anticipated, the competition was remarkably close and good. One large tent was wholly devoted to the fruit classes, and this did not hold all that was brought, and culinary Apples had to be accommodated in another structure. Although all kinds of fruits in season, if we except Pine Apples, were well represented, Grapes were the principal attraction, and of these probably there were never previously such a fine lot shown at Bath. For a collection of eight dishes of fruit the first prize was the moderate sum of £3, and yet six really good lots were staged. One exhibitor, Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton, Trowbridge, unfortunately staged eight Nectarines instead of nine, and for this oversight he had to be disqualified, or otherwise would most probably have been either first or second. The first prize was awarded to Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, who had very fine Black Hamburgh and Muscat of Alexandria Grapes, a good Longleat Per-

fection Melon, Brunswick Figs, Jefferson Plums, very poorly coloured Barrington Peaches, small Victoria Nectarines, and Windsor Pears. The second prize went to Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, who, if he had staged well coloured instead of nearly green Muscat of Alexandria Grapes, would have been easily first, so good were all his small fruits. His Black Alicante Grapes, Bellegarde Peaches, Elruge Nectarines, Jefferson Plums, Brown Turkey Figs, Blenheim Orange Melon were all very good, and the dish of Hemskirk Apricots were good for the time of year. Mr. S. Pullman, gardener to R. B. Sheridan, Esq., Frampton, was placed third for a generally creditable collection, his Hamburgh Grapes, Early Admirable Peaches, and Pine Apple Nectarines being being particularly noticeable. A certificate of merit was awarded Mr. W. Rye, gardener to J. Derham, Esq., Sneyd Park, Bristol, who also had several good dishes. Mr. Matthews, gardener to Lady Cleasby, was first for a Pine Apple, and Mr. A. Miller second. There were seven competitors in the class for eight bunches of Grapes in four varieties, and for which the first prize was the sum of £5. Mr. Pratt was easily first, having immense well finished bunches of Black Hamburgh, Muscat of Alexandria, and Alicante, and fairly large well coloured examples of Mrs. Pince—altogether an exceptionally fine collection. The second prize was awarded to Mr. W. Taylor, gardener to J. Chaffin, Esq., Bath, who had two large grandly finished bunches of Muscat of Alexandria, which weighed about 4 lbs. each, and were remarkably clean and well coloured. They were cut from a pot Vine, as were other good examples staged in another class. He also had medium-sized well finished bunches of Alnwick Seedling and Alicante, and fairly good Madresfield Court, all of which were cut from the renovated Vines alluded to on page 128. The third prize was well won by Mr. W. Nash, who was weak with Muscats, but had very fine Black Hamburghs, Alicante, and Madresfield Court. Mr. V. Down, Clifton, also had very poor Muscats, which spoilt his chance of winning a good prize, as his black sorts were very good indeed. Black Hamburghs were shown in great numbers, but Mr. Pratt was easily first with extra heavy well finished clusters. Mr. J. Ellicott, gardener to H. W. Tugwell, Esq., was second with medium-sized bunches bearing extra fine berries, and Mr. W. Iggulden was a creditable third. Mr. Pratt was also first with Muscat of Alexandria, having very large bunches and berries, but not so well coloured as were the second prize bunches staged by Mr. W. Taylor. Mr. Ellicott was a good third in this class. Mr. Taylor was the only exhibitor of Gros Colman, and took the first prize for very well finished examples. In the class for any other black variety Mr. Nash took the lead with medium-sized perfectly finished Black Alicante, Mr. Down following with good and fairly well finished Madresfield Court, and Mr. J. Carpenter was third with Alicante. Not many competed in the class for any other white variety, all the prizes going to fairly good examples of Foster's Seedling. Mr. E. C. Cheadzey, gardener to W. Duck, Esq., was first, Mr. A. Young second, and Mr. A. Miller third.

There were two classes provided for Melons and a great number of fruits were shown, but the greater portion of them as usual were poor in quality. The best green flesh was staged by Mr. C. Doons, Mr. J. Campbell following, both having unnamed varieties, and Mr. Pullman was third with Golden Perfection. In the class for scarlet flesh varieties Mr. R. Kerslake was first with Read's Hybrid, Mr. Prosser following with the same variety, and Mr. G. Marsh, gardener to J. Lysaght, Esq., was third. Peaches and Nectarines were both largely shown, and the Judges in making their awards adopted the unusual and bad practice of deciding by flavour, thus disfiguring handsome fruit without however arriving at a proper decision, more especially in the case of Nectarines. With nine Peaches Mr. Wallen, gardener to T. W. Moore, Esq., was first, staging a good dish of Violette Hâtive, Mr. Nash followed with Bellegarde, and Mr. F. Mogford was a good third with Royal George. With six Peaches Mr. Rye was first, having Ford's Seedling, a synonym probably of Bellegarde, in fine condition; Mr. Iggulden was second with good Barrington, and Mr. Pullman third. Mr. W. Shaw staged fairly good Victoria Nectarine, and was awarded the first prize; the poorest dish of Nectarines in the Show, also of Victoria, staged by Mr. J. Pearce, taking second prize, while a fine dish of Pine Apple shown by Mr. F. Cox, gardener to J. Carr, Esq., was placed third. A very poor dish of Rivers' Orange, staged by Mrs. Crouther, was yet placed first in the class for six Nectarines, Mr. Miller following with Hunt's Tawny well coloured, and Mr. F. Cox was third with fine Pine Apple. Thirty-three dishes of Plums were shown in the class for dessert varieties exclusive of Gages, the prizewinners being Mr. J. Southard first, James Tylee second, and E. Hall third, all having fine examples of Jefferson. Thirty-seven good dishes of Green Gages were shown, and with these Messrs. J. Durbin, J. Ricketts, and A. Fisher were successful. Culinary Plums were also well represented, Mr. J. Carpenter being first with Fonthill, very large, Mr. Wells second with the same variety, and Mr. Hall third with Goliath. There were twelve exhibitors of Figs, Mr. W. Scott being first with Brown Turkey, Mr. G. Garraway second, and Mr. J. Kingston third. A very fine dish of Morello gained Mr. Cox the first prize in the class for Cherries, Mr. W. Thomas being second, and Mr. E. Thomas third. Pears were largely shown, all the best early sorts being well represented. Out of thirty dishes the preference was given to a fine lot of Jargonelle exhibited by Mr. W. Bannister, Mr. E. Hall following with Beurré d'Amanlis, and Mr. T. Mogford was third. With three varieties of Pears Mr. W. J. Smith was first and E. Hall second. Twenty-nine single dishes of Apples were shown, Mr. E. Hall taking first prize for Kerry Pippin, second Mr. Mead with Irish Peach, and third Mr. W. Matthews with Kerry Pippin. Mr. E. Hall was also first in the class for three varieties, having good dishes of Beauty of Bath, Irish Peach, and Quarrenden; Mr. A. T. Hall was second and Mr. Biss third. Culinary Apples were very fine, notably such sorts as Lord Suffield, Stirling Castle, Hawthornden, Tower of Glamis, Emperor Alexander, Hanwell Souring, Cellini, and Ecklinville. Messrs. W. F. Smith, W. J. Smith, A. J. C. Biss, G. Blake, W. Britton, and Mrs. Home were the prizewinners.

VEGETABLES.—An extra fine lot of vegetables were staged, but coarseness was too prevalent, and this the Judges were disposed to encourage, no distinction being made in this respect between those produce shown by private gardeners and cotagers. No restrictions as to size of dish are contained in the schedule, and as a consequence immense piles were to be seen, especially in the case of those market growers, and greengrocers, and fruiterers who, strange to say, are allowed to compete, and unfairly compete, with private gardeners. With a collection of eight varieties Mr. Garraway was first,

having fine examples of Autumn Giant Cauliflowers, Queen of Bath Marrows, Sulham Prize Celery, Ward's Incomparable Peas, Telegraph Cucumbers, International Kidney Potatoes, Trophy Tomatoes, and Carters' Champion Runner Beans. Mr. W. Tylee was second, and Mr. T. Evry third. The best collection of six varieties was staged by Mr. E. J. Day; Mr. W. Evry being second, and Mr. Ricketts third. Mr. Ward, gardener to the Earl of Radnor, was first for a fine dish of Stamfordian Tomatoes; Mr. Ashman being a good second, and Mr. B. B. Cater third. There were also a fine lot of Potatoes, Carrots, Onions, Parsnips, Turnips, and other vegetables staged by cottagers and amateurs, none of which presented the appearance of having passed through a very trying season.

The pleasure of a visit to the Bath Show is enhanced by the pleasant and hospitable reception invariably accorded to visitors, and with a Committee so earnest and officials so zealous the exhibitions of the Society, fine as they are, can scarcely fail to increase in magnitude in future years.

NATIONAL GOOSEBERRY SHOW.

The following is a list of the prizewinners and the varieties at the recent Show in Manchester:—

DISHES OF TWELVE BERRIES.

Exhibitor.	Colour.	Name of Berry.
James Salsbury	Red	Lord Derby.
Bradley Bradley	"	Blucher.
James Hervey	"	Speedwell.
Thomas Burrows	"	Bobby.

HORTICULTURAL SHOWS.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.

SEPTEMBER 2ND AND 3RD.

THE above Society held its thirty-third Exhibition of plants, flowers, and fruit under most favourable auspices on Wednesday and Thursday last in the Pavilion and its grounds. Those who have had an opportunity of comparing the merits of the Show with those of previous years unhesitatingly pronounced it to be an advance on its predecessors, both in the quantity and quality of the exhibits. Much praise is due to the indefatigable efforts of the courteous Secretary, Mr. Councillor Carpenter, and the esteemed Treasurer, E. N. Hall, Esq., as well as the Hon. Superintendent, Mr. Chilman, and the Committee for the admirable way in which they had carried out the arrangements of the Show. The fruit and flowers were staged in a long suite of rooms in the Pavilion, which were in the evening lighted by electricity, and the plants in a large tent in the grounds, which was beautifully illuminated by Chinese lanterns. First-class bands discoursed excellent music to the multitudes of visitors who thronged the Pavilion and grounds from the opening until the close, 11 p.m. of the first day. It is to be hoped that these liberal attractions will tend to the financial success of the Society, which it appears has not latterly received the support it deserves. Plants were shown in good form, especially good being those shown by Mr. Gilbert of Hastings, and which gained the silver cup. There was a good show of fruit, the entries in the Apple and Grape classes being very numerous. Cut flowers were also shown in quantity. The stands of single and double Dahlias contained very fine blooms. Roses were fairly represented, some good examples of Teas being shown by that well-known exhibitor Mr. A. Slaughter. Some tastefully arranged groups of plants were contributed, not for competition, by Messrs. Balchin and Miles; a stand of fine blooms of Begonias by Messrs. Laing; and stands of herbaceous cut flowers by Messrs. Cheal & Sons. A great novelty in the cut flower department were some crosses and wreaths mounted with fish bones ingeniously formed to represent flowers and grasses. So well was this device carried out that it was only on a close inspection that its nature could be detected.

PLANTS.—In the classes for plants open to all England there were numerous exhibits. Mr. Rann, gardener to J. Warren, Esq., Handcross Park, won the first prize for a collection of twelve varieties, six fine-foliage and six Ferns, with splendid plants of *Dasyliion acrotrichum*, *Cyathea Smithii*, *Davallia Mooreana*, *Phœnix tenuis*, *Alocasia metallica*, *Gleichenia rupestris*, *G. glaucescens*, and others; and Mr. T. Gilbert, Springfield Nursery, Hastings, second with scarcely less beautiful examples of *Croton majesticus*, *Adiantum farleyense*, *Bihea filamentosa*, and *Dicksonia antarctica*; Mr. H. James, Castle Nursery, Lower Norwood, coming in third with much smaller plants. In the next class for eight stove and greenhouse plants in bloom, Mr. T. Gilbert was first, and consequently winner of the Ashbury cup, value ten guineas. Some grand specimens of *Statice Gilberti*, *Kalanthes coccinea superba*, *Erica æmula* and *E. cerinthoides coronata* were shown by the latter exhibitor in this class. Mr. Rann, gardener to J. Warren, Esq., came in second with large well-flowered examples of *Ericas Hartnelli virens* and *cerinthoides coronata*, *Allamanda nobilis*; and Mr. Meachen, gardener to E. Armstrong, Esq., was third with exceptionally large specimens of *Rondeletia speciosa major* and *Pimelea decussata*. For four varieties of stove and greenhouse plants in bloom, Mr. Gilbert was first with well-flowered examples of *Erica Eweriana superba*, *Allamanda nobilis*, &c.; second, Mr. Rann, with a good plant of *Lapageria alba* in his collection; and third, Mr. N. Tupp, gardener to G. Boulton, Esq., Eastbourne. In the second division, open to amateurs and gentlemen's gardeners of the county only, for four stove and greenhouse plants, four varieties, Mr. Jupp was placed first; Mr. Townshend, gardener to Capt. Thompson, Dyke Road, second; and Mr. Rann third. Mr. Meachen, gardener to C. Armstrong, Esq., Withdean, was first in the class for four variegated plants in variety, with admirably grown plants of *Croton Queen Victoria*, a well-coloured specimen, *Croton Andreanum*, *Anthurium crystallinum*, and *Yucca aloifolia*. Mr. Rann came in second, one of whose plants, *Croton Evansianus*, was particularly striking in size and brilliancy of colour. There were only two entries in this class. In the same division for a miscellaneous group of plants in or out of bloom, arranged for effect, Mr. J. Turner, gardener to Major Way, Wick Hall, was deservedly awarded first prize for a very pretty group, the arrangement being light and pleasing, and Mr. Meachen second. For a group of Ferns, arranged for effect, Mr. Jupp first with a choice and pleasing group, and Mr. Meachen second.

For a group of Fuchsias arranged for effect (open class) the first prize was awarded to Mr. C. Fluck, gardener to J. Smith, Esq., for a pretty group, and the second to Mr. Meachen. In the open and county classes devoted to Geraniums the exhibits were very good. Mr. Gilbert, Springfield Nursery, was first in the open class for six varieties of Zonal Pelargoniums (not scarlet); Mr. Meachen second, and Mr. Townshend third. For four scarlet Zonals in four varieties, Messrs. Gilbert first, Townshend second, and Meachen third. Six double distinct varieties, first Mr. Gilbert, second Mr. Meachen, and third Mr. Hugget. For four varieties of Zonals in the county class, Messrs. Townshend first, Meachen second; and four scarlets, Mr. Townshend first, and Mr. Meachen second. In the open class for a group of Coleus arranged for effect, Mr. Jupp was placed first for a showy group, and Mr. Fluck second. For a group of Begonias (open class) arranged for effect, first Mr. J. Spottiswood, gardener to E. Duddell, Esq.; second Mr. Meachen; and third Mr. Mann, gardener to C. Gilbert, Esq., Eastbourne. The table plants shown were very good, Messrs. Turner, James, and Meachen securing the prizes for twelve varieties; and Messrs. Miles, Turner, and Blake for six varieties.

CUT FLOWERS.—There was a good display in both the open and county classes devoted to cut flowers, the Dahlias, single and double, and Asters being very fine. In the open classes for forty-eight dissimilar blooms of show Dahlias Mrs. Seale, Vine Nurseries, Sevenoaks, was awarded first for really splendid blooms, of which the most conspicuous were Flag of Truce, Geo. Dickson, Julia Davis, James Cocker, Emily Edwards, &c.; Messrs. Cheal & Sons, Lowfield Nurseries, Crawley, coming in second with scarcely inferior blooms. Mrs. Seale was first again in the class for twenty-four Fancies; and Messrs. Cheal & Sons second. In the class for twenty-four singles, in bunches of six blooms, a transposition took place in the positions of the two latter winners, Messrs. Cheal being first, and Mrs. Seale second. In the first-named winner's stand were charming blooms of Lady of the Lake and Formosa, two of their own new seedlings. Messrs. Cheal were also first for twelve varieties of Pompons. For twelve dissimilar blooms (Show) first Mr. Boothroyd, second Mr. Vincent, third Mr. Simmons. Twelve Fancy, first Mr. Boothroyd, second Mr. Vincent, and third Mr. Simmons. For twelve singles, Messrs. Maxted, Vincent, and Morgau. In the county classes for twelve varieties show Dahlias, Messrs. Vincent and Simmons were the prizewinners, as also in the class for six Fancies. For twelve varieties of singles in bunches of six, the prizes went to Messrs. Vincent, Simmons, and Hobden respectively.

Roses were shown in fairly good form for such a season as the present. In the open class for twenty-four varieties in bunches of three, the premier prize was won by Messrs. Woodland & Son, nurserymen, Cooksbridge, with fine blooms of Cheshunt Hybrid, Duke of Edinburgh, Marie Verdier, Ferdinand de Lesseps, &c.; the second going to Mr. W. Balchin, nurseryman, Brighton, who staged good blooms of Souvenir de la Malmaison and Capt. Christy, and the third to Mrs. Seale. Mr. A. Slaughter was first for twelve varieties in bunches of three, this exhibitor staging very fine blooms of Alfred Colomb, Baroness Rothschild, and Fisher Holmes; and Mr. W. Virgo, Guildford, second. For twelve varieties of Teas or Noisettes (single blooms) Mr. Slaughter was again placed first with Madame Lambard, Innocente Pirola, Jean Pernet, and Catherine Mermet in capital condition; and Mr. W. Piper, Uckfield, second. In the county classes Mr. A. Slaughter secured a first place for twelve varieties of Tea or yellow (single blooms), and Mr. Vincent second. For twelve varieties single trusses Mr. A. Slaughter took the lead again with grand blooms of John Stuart Mill, Marie Baumann, and Chas. Lefebvre; and Mr. Simmons, gardener to the Rev. R. C. Hales, second.

Hardy herbaceous cut flowers were shown in quantity. In the open class for thirty-six varieties, Mr. W. Balchin first; Mr. J. Vander Rees, Tooting, second; and Messrs. Cheal third. In the county class Messrs. Vincent, Gore, and Rapley were the winners. Cut flowers in bunches, twenty-four varieties, open class, first Mr. W. Archer, second Mr. H. James. County class, Mr. Vincent first. Asters were shown in capital form, especially the French varieties. Mr. Morgan was first for a collection of twenty-four varieties of French quilled, second Mr. W. Archer, and Mr. W. H. Vincent third. For twenty-four varieties of German quilled, first Mr. H. Archer, and second Mr. Morgan. In the county classes Messrs. White, Blake, and Wickham were the winners with twelve varieties of French, and Messrs. Wickham and Hobden with twelve German Asters. For a very choice and artistically made wreath, first Mr. Webber, Tonbridge; Mr. Chard second, and Mr. Brown third.

The table decorations were very good, the arrangement of the flowers being very light and pleasing to the eye, especially the premier exhibit by Mr. R. Chard, Clapham Common; Mrs. Seale was second, and Miss Gould third. The bridal and ballroom bouquets were very good examples of artistic taste, Mr. J. R. Chard winning the first, and Mr. Brown, florist, Richmond, the second prize. Mr. Chard was first for a very tastefully arranged spray for a lady's dress, Mr. W. Brown second, and Mr. Chapman third. Messrs. Webber, Woollard, Seale, and Gadd were the winners for six buttonholes, and Messrs. J. R. Chard, J. W. Chard, and Wetton for baskets of cut flowers.

FRUIT.—The fruit classes were well represented both in the open and county divisions, Pears, Apples, Peaches, Cherries, and Grapes being of good quality. In the open classes for a collection of twelve dishes, Mr. Goldsmith, gardener to C. A. Hoare, Esq., Beckenham, was first with dishes of splendid fruit of Victoria Nectarine, Moorpark Apricot, Astrachan Apple, Ashton Park Melon, Muscat of Alexandria and Black Prince Grapes. Mr. Dixon, gardener to Sir S. Wilson, Bart., second with fine fruit of Brunswick Figs and Lord Napier Nectarine. For a Pine Apple, any variety, Mr. Bates was awarded a first prize. In the classes for Grapes the bunches were remarkable for size, but somewhat deficient in colour, especially the Muscats. Mr. Hotston, gardener to R. H. Penny, Esq., was first for three bunches of Black Hamburgh. Mr. Inglis, gardener to Cunliffe Lister, Esq., second, and Mr. Miles third. Mr. J. Miles, Bristol Nursery, Kemp Town, was first with three bunches of white Muscats, second C. J. Goldsmith, and third Mr. Spottiswood. For six bunches Black Hamburgh, first Mr. Hotston, second Mr. Warren, gardener to Mrs. Hankey; and third C. A. Goldsmith. For six bunches white Muscats, Mr. J. Miles first, C. A. Goldsmith second, and J. Spottiswood third. In the class for a single Melon for flavour, Mr. Ford, gardener to C. A. Halbund, Esq., first; Mr. H. Stringer,

second; and R. Spinks, third. For a dish of eight Peaches Mr. J. Miles was first with splendid fruit of Bellegarde, and Mr. W. Balchin second with Princess of Wales, and Mr. Walder third. Mr. Biggs was first for a dish of Nectarines, Mr. Maxted second, and Mr. Inglis third. For a dish of Plums, Mr. Maxted first, Inglis second, and F. Fuller, Esq., third. The latter was first for a dish of Green Gages, Mr. J. Holman second, and Mr. Booth third. For a dish of Morellos Mr. Booth first, Mr. O. Goldsmith second, and Mr. Ford third. Mr. Butler, Lancing, was first for Figs with a variety named Madagascar, and Mr. Miller second. Mr. C. Goldsmith was first for a dish of dessert Pears, Mr. Durrant second, and Mr. Carter third. For a dish of dessert Apples, Mr. Virgo first with Worcester Pearmain, Mr. Tupp second and Mr. Ford third. Messrs. Booth, Miller, and Goldsmith were the winners for a dish of culinary Apples. For a collection of six varieties of Grapes, Mr. Chatfield, gardener to T. Holman, Esq., was first; and Mr. Gore, gardener to Captain Taylor, Hastings, second.

In the county classes for a dish of culinary Apples the winners were Messrs. Gore, Wickham, and Hotston. For a dish of Figs Mr. Butler was awarded a first prize. For a dish of dessert Apples, Mr. Carter first, Booth second, and Gore third. Dish of Green Gages, Messrs. Holman, Booth, and Jupp. Dish of Plums, Messrs. Gore, Johnstone, and Hobden. Dish of Morellos, Messrs. Booth, Ford, and Hobden. Dish of Tomatoes, Messrs. Walter, Stringer, and Blake.

Six dishes of Apples, Messrs. Gore, Remnant, and Blake. Dish of Peaches, Messrs. White, Walder, and Inglis. Dish of Nectarines, Messrs. Biggs, Dixon, and White. For a Pine Apple, any sort, Mr. Brown first. For a Melon for flavour, Messrs. Stringer, Ford, and Langridge. Dish of Pears, Messrs. Remnant, Spottiswood, and Wicham. All of the foregoing were the winners in the order of their respective names. The Grapes shown in this division were very good, Messrs. Godfrey, Hotston, and Spottiswood taking the prizes for three bunches of Black Hamburgs, and Messrs. Spottiswood, Chatfield, and Ford for three bunches of white Muscats.

Specimens of the male and female cones of *Araucaria imbricata* were exhibited by Mr. W. Greenyer, gardener to Major Lyou, Goring Hall, Worthing.

GLASGOW AND WEST OF SCOTLAND.

THE general autumn flower Show of this Society was held in St. Andrew's Hall on Wednesday, September 2nd, and proved to be the finest exhibition that has taken place in Glasgow for about twenty years. The most notable collection of plants (exhibition only) was that contributed by Messrs. J. and R. Thyne, Great Western Nurseries, Kelvinside. The platform in the large hall was filled with choice plants, Palms, Pitcher Plants, rare Orchids, and highly coloured Crotons. First-class certificates were awarded to a fine group of Croton Thynae, also Croton Regina, the latter being shown for the first time. The whole arrangement of the platform was such as to command the highest admiration of both Judges and visitors. In another part of the Hall the same firm had also on exhibition a magnificent floral cross composed of Stephanotis, Orchids and Tuberoses. This was very much admired, as was also a fine large wreath and two bouquets, one of which was composed of Orchids, Stephanotis, and Tuberoses, most beautifully and tastefully arranged.

Councillor Campbell, fruiterer, 18, Gordon Street, filled a large table with fine specimens of home and foreign fruit, which collection was very highly commended for quality and tasteful arrangement. Messrs. W. Aitken and Sons, Lenzie, had fine stands of Carnations, Pentstemons, and Gladioli, which were deservedly admired. Messrs. Dobbie & Company, Rothesay, sent stands of their famous strains, comprising Sweet William, of extra quality; Pansies, Pentstemons, Antirrhinums, Spiral Candytuft, all seedlings raised by this firm, and highly commended. They also exhibited a box of their new (Model) white Turnip, a variety of much excellence. Mr. William Campbell, nurseryman, Auchencrath, had a very choice collection of Carnations and Picotees, a Carnation named Snowflake being awarded a first-class certificate. Mr. John Sutherland, Lenzie, had stands of seedling Pansies, many of which will occupy a prominent position at future shows, and to which were awarded several first-class certificates. Messrs. A. Patison and Son, Paisley, sent a stand of a seedling Pansy named Lord Rosebery, which was awarded a first-class certificate. Mr. Thos. Smith, nurseryman, Stranraer, showed a stand of Roses. Mr. Smith has earned a high reputation for the quality of his exhibits, and was very highly commended for this fine collection. Mr. Cuthbertson, Rothesay, showed some fine stands of the old Scotch Marigold, which has been very much improved by him. Mr. Lister of Rothesay had a very fine collection of Show and Fancy Pansies, very highly commended. Mr. J. Baxter, Daldowie, exhibited two seedling Violas, very distinct and beautiful. Mr. W. Kerr, Dargavil, Dumfries, sent a splendid collection of Potatoes, comprising seventy varieties, among which were some fine seedlings not yet in commerce, a fine specimen of which was named Frank Gibb Dougall, in compliment to our esteemed Secretary. A certificate of merit was awarded this collection.

Among the exhibits brought for competition first place must be given to the collection of plants arranged for effect, and filling tables 12 feet long by 6 feet wide; five collections were shown. The first prize was awarded to James Mitchell, gardener to Mr. Hunter, Newmains, for a beautifully arranged and well finished group, comprising a good specimen of *Cattleya crispa*; two fine Yuccas, a beautiful Palm, some Crotons, Ferns, and Grasses were the features of this group. The second prize was awarded to Mr. John Mathieson, gardener to J. L. Henderson, Esq., West Bank, Partick; this group was composed of Palms, Villetas, Nerines, a few Orchids, and a well-bloomed *Ixora*, a want of finish spoiling what was otherwise a fine group. Third prize was awarded to Mr. A. Millar, gardener to Mr. Ward, Ballreston, the plants in this collection being too large for the size of the table. These tables were a valuable contribution and an important feature of the Show.

In the class for four stove and greenhouse plants, Mr. Hogg, gardener, Aitkenhead, showed splendid specimens of *Statice profusa*, 3 feet in diameter, densely bloomed; a good *Erica Irbyana*, *Phonocoma prolifera* Barnesii, well grown; and *Anthurium Andreanum*. Mr. Hogg was also first for exotic Ferns; *Gleichenias Mendelii*, *dichotoma*, and *Spelunca* being very large and fresh, and a splendid plant of *Microlepia hirta cristata* was also notable. The same exhibitor had the only three Orchids in the Exhibi-

tion; Mr. Combie, Greenock, having the prize for the single specimen Orchid. Mr. John Mathieson had first prize for foliage plants, his Croton Weismanni and Cycas circinalis being in splendid condition. The foliage plants filled a large table and made a splendid show.

The first prize for twenty-four Dahlias was gained by Mr. M. Campbell of Auchinraith. Prominent in his collection were finely finished examples of the following varieties:—Statesman, Hon. Mrs. Percy Wyndham, Gaiety, W. H. Williams, Earl of Ravensworth, Prince Bismarck, Mrs. Gladstone, Mrs. Langtry, Lottie Eckford, and a most perfect bloom of Harrison Weir. A silver medal was awarded for these blooms. Messrs. Jas. Cocker and Son, Aberdeen, had first place for twenty-four blooms of Roses. Some of the best in this collection were Merveille de Lyon, White Baroness, Duke of Teck, Pride of Waltham, Countess of Rosebery, John Stuart Mill, Marie Baumann, and A. K. Williams. Pansies were well represented, Mr. John Sutherland taking the lead with a stand of perfect blooms, remarkable for substance, size, and smoothness of texture. Single Dahlias were well shown by Messrs. John Lamont & Son, Musselburgh, some of the best being Beauty of Cambridge, White Queen, Zulu Improved, B. S. Williams (new), Warrior (new), White Paragon, Paragon, Robert Fleming, Walter Ware, the Clown, James Cocker, and Negress. Mr. E. Boyes, Uddington, had fine specimen Ericas, his E. Marnockiana gaining the prize for the most meritorious plant in the Exhibition. Mr. A. Niven, gardener, Loch Brae, showed a fine specimen Tree Fern, Cyathea dealbata, very handsome.

The vegetables formed a remarkable show, the chief prizetaker being Mr. D. McBean, gardener to A. Cunningham, Esq., Craigends, Johnstone. His vegetables were superb and easily gained the first position. Mr. McBean had also first for Leeks, Onions, Carrots, Cauliflowers, Savoys, Parsley, and Parsnips, his Onions and Leeks being marvels of high cultivation. Mr. Alexander Bogie, gardener, Auchans House, Kilmarnock, showed the best Potatoes, his Village Blacksmith being very fine.

Fruit was not largely shown. The bunches of Alicante and Black Hamburgh Grapes were particularly well done. White Grapes were not so well shown, a want of finish being apparent in some of the best bunches. The principal competitors for fruit were Messrs. Alexander Crosby, Buchanan Gardens; J. Procter, Glenfinnert, Greenock; and Wilson, Ayr; James Mitchell, Newmans; Donald McBean, Robert Strathdee, John Maul, and Henry Andrew.—G. R.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 8TH AND 9TH.

ALL available space in the conservatory at South Kensington was fully occupied with exhibits on Tuesday and Wednesday last, the Grapes, Plums, miscellaneous fruits, Dahlias, Gladioli, and other flowers together forming one of the largest and best shows held there this season. Throughout Tuesday afternoon and evening the building was crowded with visitors, and there was no part of the International Exhibition attracted so much attention as this. The important series of shows held there this year are now drawing to a close, as only two more are announced, which take place next month.

GRAPES.

The schedule provided no less than twenty-seven classes for Grapes, two bunches of each, and three prizes were offered in each class of 30s., 20s. and 10s., or a total of £81, probably the largest amount ever contributed for Grapes at one exhibition in London. Classes were specially devoted to twenty-six varieties, and with those not in competition there must have been over forty varieties represented, though some of these were only curiosities, and the relative popularity of the different sorts was well shown by the number of entries. The competition was not quite so keen as might have been expected, but in all the leading classes fruit of excellent quality was staged, and the weakest and least satisfactory samples were found in the classes for varieties that are not considered as standard Grapes, but rather as super-numeraries, to vary the supply. Black Grapes were decidedly superior to the white varieties if we except Muscat of Alexandria, which was admirably shown by several competitors, but especially by the successful exhibitor at the recent Crystal Palace Show, who was again victorious at Kensington.

Taking the classes in the order named in the schedule, the following were the awards:—

Alicante.—The seven competitors in this class all staged good bunches, and the three prizewinners' contributions were remarkable for their dense even bloom. Mr. Howe, gardener to H. Tate, Esq., Park Hill, Streatham, was awarded first honours for large well-developed bunches, one being particularly handsome, and all that could be desired in colour. Mr. J. J. Lowry, gardener to J. Macandrew, Esq., Belmont, Mill Hill, followed very closely, being but few points behind, and Mr. Hollingworth, gardener to J. T. Campbell, Esq., Woodseat, Uttoxeter, was third with smaller bunches, but of handsome shape and colour.

Alwick Seedling.—This was a remarkable class, for although there were only five entries, the Judges deemed the Grapes so meritorious that a prize was awarded to each exhibitor—namely, a first, two seconds, and two thirds. The examples were all good, and in bloom and general finish there was very little difference between them, but the bunches varied slightly in size, and this seemed to be the chief guide to the awards. The premier honours were accorded to Mr. H. J. Clayton, Grimston Park, Tadcaster, for handsome bunches and berries superbly coloured. Mr. Wallis, gardener to the Rev. W. Sneyd, Keele Hall, Newcastle, was second with smaller but compact, even, and beautiful bunches. Mr. Roberts, gardener to Messrs. Rothschild, Gunnersbury Park, Acton, was equal second with finely coloured examples. Mr. J. Hudson, gardener to H. J. Atkinson, Esq., M.P., Gunnersbury House, Acton, and Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, were equal thirds, both showing highly creditable bunches.

Black Hamburgh.—Of the five exhibitors Mr. J. Roberts had decidedly the best specimens of this variety both in size of berries and colour. Mr. J. Vert, The Gardens, Audley End, was second with good bunches and berries, but slightly wanting in colour. Mr. J. Read, Moat Mount, Mill Hill, was third with bunches and berries of medium size, but slightly rubbed.

Black Prince.—Only two pairs of bunches of this variety were exhibited,

Mr. Baird, gardener to C. A. Daw, Esq., Homefield, Ealing, taking the lead with the characteristic long bunches of good colour. Mr. C. J. Goldsmith, gardener to C. H. Hoare, Esq., Kelsey Manor, Beckenham, was placed second with smaller but good examples.

Buckland Sweetwater.—With large handsome bunches and berries, but not highly coloured, Mr. J. Roberts was the most successful amongst five exhibitors, Mr. S. Castle, West Lynn, Norfolk, being second with smaller bunches but equally fine berries; Mr. G. R. Allis, Old Warden Park Gardens, Biggleswade, following with well-ripened but smaller bunches.

Duke of Buccleuch.—None of the exhibits in this class could be considered perfectly satisfactory, though the premier bunches from Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, were large, the berries fine, and one of them very clean. Mr. G. Tucker, gardener to J. L. Lovibond, Esq., Starts Hill, Farnborough, was second with large but rather irregular bunches and fine berries; Mr. Baird being third with similar but smaller bunches.

Dutch Hamburgh.—Though a very handsome Grape when well grown this does not appear to be a favourite with exhibitors, for there was only one entry, Mr. J. Read gaining the first prize for bunches of medium size, the berries fine and colour excellent.

Dr. Hogg.—This fine-flavoured variety was also only represented by one exhibitor, Mr. E. Hill, gardener to Lord de Rothschild, Tring Park, Tring, who was awarded the first prize for a fine bunch of medium-sized berries and well coloured.

Foster's Seedling.—Seven pairs of good bunches of this variety were shown, Mr. Allan leading with particularly good samples, very notable for the size of the berries. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, was second with good-sized bunches well ripened; and Mr. J. Horsefield, gardener to Lord Heytesbury, Heytesbury, Wilts, was third with highly coloured examples, rather smaller in bunch and berry than the preceding.

Golden Queen.—There was nothing in the appearance of the two pairs of bunches staged to excite much admiration, for all the "golden" to be seen was in the name, and they both had a rather green, or what some might term a "dirty" appearance. Mr. H. Folkes, gardener to T. F. Halsey, Esq., M.P., Gaddesden Place, Hemel Hempstead, and Mr. Wallis were the prizetakers in that order.

Gros Colman.—With the exception of the first-prize bunches from Mr. R. Dawes, gardener to the Hon. Mrs. Meynell Ingram, Temple Newsome, the exhibits in this class were not so good as we sometimes see at later shows; those just named were, however, large in bunch and berry, and admirably coloured. Mr. A. Smith, gardener to W. H. Sewell, Esq., Warren Hill, Loughton, was second, very large bunches, medium size berries, and slightly wanting in colour; Mr. Tucker being third with small well-coloured bunches.

Gros Guillaume.—Under the general but erroneous name of Barbarossa two huge bunches of Gros Guillaume were staged by Mr. Dawes, and were adjudged the first prize. The bunches were not only large, but well proportioned and of good colour.

Gros Maroc.—As at the Crystal Palace, this very promising Grape was capitally represented, and it appeared to well deserve the opinion expressed by an experienced grower, that it is "a first-rate variety, and one which is fast gaining favour." Mr. J. Roberts had the best of the five pairs entered, the bunches being compact and well formed, the berries large and the colour beautiful. Mr. G. T. Miles and Mr. J. Wallis followed very closely, there being few points between them and the first.

Lady Downe's Seedling.—This thoroughly useful late Grape was shown by six competitors, Mr. Hollingworth leading with large handsome bunches of fine colour much ahead of the others. Mr. Wallis was second with smaller bunches, and Mr. Allis third with similar but well-coloured examples.

Madresfield Court.—All the bunches staged by the five exhibitors were even and well set, but two or three were slightly deficient in colour. Mr. Hudson won first honours with large bunches bearing a splendid bloom. Mr. Goodacre and Mr. Vert following closely.

Mrs. Pearson.—Two of the contributions in this class—namely, the first and second from Mr. Allan and Mr. Horsefield, were remarkable for their high colour, the second bunches differing only in being rather smaller. The third-prize bunches from Mr. Wallis were somewhat green, and the same remark applies to the two bunches that did not take a position amongst the prize-winners.

Mrs. Pince.—The competition was good in this class, there being seven entries, but except the first-prize bunches from Mr. Pratt, Longleat Gardens, Warminster, they were not so well coloured as this variety should be when at its best. Mr. Pratt's bunches were solid and handsome, and bore a fine dense bloom. Mr. Smith was second also with good bunches, and Mr. Wallis third, the last named samples being rather red.

Mill Hill Hamburgh.—Two good examples of this Grape were exhibited, but neither were quite up to the character of the variety as regards size of berries. J. McIntosh, Esq., Duneeven, Oatlands Park, secured the first place with good bunches and berries, Mr. J. Read being second with smaller berries but rather better colour, though this variety is rarely seen first-rate in this respect.

Muscat Hamburgh.—First honours were obtained by Mr. Goodacre with even well-proportioned bunches of satisfactory colour. Mr. Horsefield followed closely, and Mr. Allan was third with large bunches, but rather wanting in colour.

Muscat of Alexandria.—The keenest competition in all the classes was that for this favourite Muscat, nine pairs of fine bunches being staged; but, repeating his success at the Crystal Palace last week, Mr. J. J. Lowry was again accorded premier honours for the handsome bunches which are duly praised elsewhere. Mr. Pratt and Mr. Roberts followed in that order, the second having large bunches not so well coloured, and the third smaller but well ripened bunches.

Various.—In several classes there was little competition, and they can be disposed of in a few lines. Of Royal Muscadine Mr. Read had the only examples, and was awarded the third prize. With West's St. Peter's Mr. Baird was first. Many good bunches of capital colour, but there was no competition. Messrs. Hollingworth, Edmonds, and Vert were the prize-winners with Trebbiano, all showing large bunches. Messrs. Roberts and Hollingworth were first and second respectively with White Tokay, both

fairly good. For any other variety than those specially provided for in the preceding classes there were five entries; Mr. J. Wells, gardener to R. Ravenhill, Esq., Fernhill, Windsor Forest, being first with Cooper's Black, a variety with large oval berries, and bearing a dense blue bloom. Mr. Horsefield was second with Chatsworth Seedling in good condition, and Mr. Roberts was third with the finely flavoured Duchess of Buccleuch. Black Monnuka and Black Frontignan were also shown in this class, but did not gain prizes.

Messrs. Webber & Co.'s Prizes for Grapes.—Three prizes were offered by this well-known firm of fruiterers, Covent Garden, for the best box or basket of Grapes not less than 12 lbs., packed for market, so as to realise the highest prizes. These classes always attract much attention, and the seven contributions were closely examined by the Judges, with the result that Mr. S. Castle, West Lynn, was placed first with some good examples of Black Hamburg, closely packed in a handle basket. The stalks were secured to the side of the basket with string, the bunches resting on a bed of wool covered with tissue paper, and over the basket sticks were arched to bear the necessary covering and keep it from the Grapes. Mr. Goodacre was second with the same variety, similarly packed and nearly as fine condition. Mr. T. Turton, gardener to John Hargreaves, Esq., Maiden Erlegh, Reading, was third also with Black Hamburg, but packed in a box on moss covered with tissue paper.

Miscellaneous Fruits.—Amongst the numerous exhibits not in competition, one of the most meritorious were the Vines in pots from Messrs. H. Lane & Sons, Great Berkhamstead, for which a silver-gilt medal was awarded. There were seven Vines, each 5 to 6 feet high, trained round stakes, and bearing from twenty to thirty bunches each of the following varieties—Black Hamburg (2), Foster's Seedling (2), Gros Colman, Alicante, and Gros Maroc. All these were fully ripened, and they formed a most interesting feature in the fruit display. Mr. W. Roupell, Harvey Lodge, Roupell Park, London, was awarded a silver medal for a collection of Grapes, comprising the following—White Frontignan, Grizzly Frontignan, Purple Constautia, Madresfield Court, very good; Muscat of Alexandria, Muscat Hamburg, Mrs. Pearson, Dr. Hogg, and Chavonsh, a white variety, described as a great favourite with the late Sultan of Turkey, but which has been found worthless in this country. Some Vines of the American and French Strawberry Grapes, with a variety named General della Marmora, were trained in the form of an arch, to show how ornamental they are in this way. Fourteen varieties of Grapes were sent from Chiswick, representing Royal Muscadine, Dutch Hamburg, Black and White Frontignan, Chasselas Rose, Miller's Burgundy, Royal Ascot, Mill Hill Hamburg, Ascot Citronelle, Golden Hamburg, Chasselas Vibert, and the Currant Grape, all very interesting, and some rarely seen in cultivation.

An extensive and handsome collection of Apples was shown by Messrs. W. Paul & Son, Waltham Cross, which was honoured with the award of a silver medal. There were seventy dishes, and nearly all distinct varieties, some particularly handsome fruits of the following being shown:—Peasgood's Nonesuch, Alfriston, Cellini, Ribston Pippin, Tower of Glamis, Court-Pendù Plat, Blenheim Pippin, Hawthornden, Keswick, Bedfordshire Foundling, Winter Pearmain, Evagil, Lord Derby, Stirling Castle, Warner's King, and Dumelow's Seedling. A similar award was granted to Messrs. J. Cheal & Sons, Crawley, for a varied and interesting collection, comprising a large number of Apples, handsome fruits of the leading varieties, a good collection of Plums, Coe's Golden Drop, Pond's Seedling, White Magnum Bonum, Jefferson's, and the Myrobalan or the Cherry Plum being amongst the best. Five clusters of the prolific, handsome, American cut-leaved Blackberry, which is becoming so great a favourite, were also shown, and a number of brightly coloured and curiously formed Gourds. Messrs. G. Bunyard & Co., Maidstone, contributed some very beautiful fruits of their fine new Apple, Lady Sudeley, which are distinctly streaked with bright crimson, giving them a handsome appearance. Samples of the Farleigh Damson were also shown from trees on their own roots and from budded trees, the latter being much larger than the others. A very ornamental rich crimson Crab, named the American Hyslop, was shown together with good fruits of Dr. Jules Guyot Pear.

Plums were shown by numerous exhibitors and mostly in excellent condition, bronze medals being awarded for the seven following collections:—Mr. Bates, gardener to Mrs. Meek, Poulett Lodge, Twickenham, showed twenty dishes of Plums, all fine fruits, and including some of the best in the Exhibition. The principal varieties were Coe's Golden Drop, Magnum Bonum, Prince Englebert, Victoria, Washington, Diamond, Pond's Seedling, Jefferson, Denbigh, Guthrie's Gage, Transparent Gage, and Early Gage. Mr. Ford, Leonardslee, Horsham, showed twenty-six dishes mostly Plums but a few fruits of William's Bon Chrétien from Pear and Quince stocks were included. The best Plums were Goliath, Diamond, Magnum Bonum, Pond's Seedling, Cox's Emperor, Victoria, The Czar, and Early Orleans. Mr. W. Divers, Wierton Place, Maidstone, had some large handsome Brunswick Figs, and the following Plums were excellent in size and appearance:—Prince Englebert, Pond's Seedling, Prince of Wales, Nectarine, Diamond, Coe's Golden Drop, Magnum Bonum, and Jefferson. Mr. J. Gore, The Gardens, Glenleigh, Hastings, had thirteen dishes of Plums, comprising Jefferson, Magnum Bonum, Deniston's Superb, Kirke's, Violette de Galopin, Green Gage, Coe's Golden Drop, Cox's Emperor, Victoria, and Diamond. Mr. Abel Phillips, Glaston, Uppingham, had eleven varieties of Plums, Mr. J. Rose, Lockinge Gardens, Wantage, fourteen dishes, and Mr. Walter Dance, Gosfield Hall, Halstead, had twenty-six dishes, the varieties being similar to those already noted.

A large collection of Plums was also sent from Chiswick, in which the following varieties were represented:—Victoria, Orange, Drap d'Or, d'Esperen, Reine Claude Rouge, Bryanston Gage, Wineson, Yellow Magnum Bonum, Double Altesse, Reine Claude d'Angoulême, La Delicieuse, Nelson's Victory, Pond's Seedling, Overall, Lawson's Golden Gage, and Dammas d'Espagne. Mr. B. N. Foster, Ewhurst, Guildford, had two dishes of Plums, and Messrs. W. Paul & Son had a dish of Angelina Burdett Plums in good condition. Messrs. Hooper & Co. showed a collection of twelve varieties of Tomatoes, all fine even fruits.

DAHLIAS.

The display of these was all that could be desired, the blooms of good substance, symmetrical and bright in colours, all the sections, Show, Fancy, Pompon, and single varieties, being largely and well represented. Full

lists of the varieties are given in our report of the National Dahlia Show last Friday and Saturday, and it is not therefore necessary to repeat them here, so we shall only give the prizewinners in the principal classes.

With forty-eight Show varieties Mr. C. Turner, Slough, was the most successful, taking premier honours with very handsome blooms, being followed closely by Mr. W. Boston, Bedale, Yorkshire, and Messrs. Keynes, Williams and Co., Salisbury. For twenty-four Show varieties Messrs. Rawlings Bros., Romford, were deservedly first; Messrs. Saltmarsh & Sons, Chelmsford, and Mr. J. Walker, Thame, being second and third. Messrs. Keynes, Williams, and Co. had the best twenty-four Fancy varieties, and Messrs. Saltmarsh the finest twelve Fancy varieties: Messrs. Turner, Boston, Rawlings, and Walker following in the two classes. In the amateurs' class for twenty-four Show varieties, Mr. J. Spoor, Prospect Cottage, Musgrave, Low Fell, Gateshead, was awarded premier honours, staging highly satisfactory blooms. Mr. H. Glasscock, Rye Street, Bishop's Stortford, and Mr. C. Hockney, Greenfield House, Stokesley, Yorkshire, were second and third respectively. For six Fancy varieties, W. Keith, Esq., Cornwall, Brentwood, Mr. Glasscock, and Mr. Prince were the prizetakers.

There was a beautiful display of Pompon and single varieties, the finest of the former being from Messrs. Keynes, Williams & Co., and of the others from Messrs. J. Cheal & Son, whose stand of singles was one of the best ever shown. Mr. Turner and Messrs. Keynes & Co. also exhibited in these classes. Mr. C. Turner's prizes for Dahlias brought good competition, Messrs. Keith, Glasscock, Walker, Garratt, and Henshaw securing the honours.

Miscellaneous Collections of Flowers.—Considerable space was occupied with the non-competing exhibits, and one of the most effective displays was that provided by Messrs. H. Cannell & Sons, Swanley, who had extensive collections of Dahlias, representing all the leading varieties, and including many novelties of great merit. Very noticeable was the large white Dahlia Mont Blanc, some blooms of which were 8 inches in diameter. Several pretty forms of the Jnarezi type, shown as Cactus Dahlias, were also very good, one being bright yellow, another plum-coloured, together with the pale yellow Mrs. Hawkins, and the white Constancy. As a decorative Dahlia, Fascination, rosy crimson with a white centre to each floret, was distinct and beautiful, and a magnificent bloom of Mrs. Gladstone attracted much attention. Tuberous Begonias, Asters, and many other specialties were comprised in this grand collection, for which a silver-gilt medal was awarded. A similar honour was adjudged to Messrs. Kelway & Son, Langport, for a magnificent collection of 120 Gladioli spikes of numerous varieties, several of which were certificated. Medals of equal value were also adjudged to Mr. T. S. Ware, Tottenham, for his superb group of hardy flowers, which also comprised numerous Dahlias of all sections; and to Messrs. J. Laing & Co., Forest Hill, for a brilliant group of Tuberous Begonias very tastefully arranged with Palms, Ferns, &c. Bronze Banksian medals were awarded to the New Plant and Bulb Company for a group of Lilium auratum varieties, and to Mr. Boothroyd, gardener to H. Coleman, Esq., Woodville, Dover, for a choice collection of stove and greenhouse flowers.

COMMITTEES.

FRUIT COMMITTEE.—Present, F. D. Godman, Esq., in the chair; Messrs. G. Bunyard, J. Willard, J. Roberts, G. T. Miles, T. Francis Rivers, Jos. Ellam, C. Silverlock, C. Ross, G. Goldsmith, W. Paul, T. B. Haywood, R. D. Blackmore, Arthur W. Sutton, Harrison Weir, G. Paul, J. Woodbridge, and Dr. R. Hogg. Mr. S. Mortimer, Swiss Nursery, Farnham, sent a seedling Tomato, and also a seedling Melon, both of which were referred to Chiswick. W. Roupell, Esq., Harvey Lodge, Roupell Park, sent fifteen varieties of Grapes. These were all grown in pots, and had not produced large-sized bunches. A letter of thanks was awarded Mr. S. Cooper, Fern Cottage, Sunninghill; and Mr. Gough, The Gardens, Harefield Grove, sent seedling Tomatoes, which were referred to Chiswick.

Mr. Beckett, The Gardens, Aldenham Park, Elstree, sent six brace of a seedling Cucumber of excellent growth, to which a vote of thanks was awarded. Mr. Herrin, Gerard's Cross, sent branches in fruit of a seedling Raspberry called Late Prolific. It appears to be an early form of the autumn-bearing varieties, and before coming to a decision the Committee desired to see it at next meeting, with particulars of cultivation. Messrs. R. Veitch & Son, of Exeter, sent a seedling Peach, the produce of a cross between Belle de Vitry and Galande, which was not considered superior to varieties already in cultivation; also another raised from crossing Late Admirable and Belle de Vitry. A vote of thanks was awarded. They also sent a bunch of a Grape introduced from France, under the name of Garibaldi, which proved to be one of the American Fox Grapes.

Mr. Miles, The Gardens, Wycombe Abbey, exhibited a splendid bunch of Gros Maroc Grape, beautifully finished, the berries being large and finely bloomed. It was probably one of the finest bunches of this variety that has ever been exhibited. Mr. George Bunyard of Maidstone exhibited a branch of the Crittenden Damson studded with fruit; he also had a dish of the fruit from budded trees, which is much larger than that grown upon those raised from suckers. Mr. R. Dean of Ealing also exhibited fruit of the Crittenden Damson. Mr. R. A. Bray of Bedford sent a dish of Williams' Bon Chrétien from standards. Messrs. Webb & Son of Stourbridge sent a seedling Melon called Beauty of Wordsley, which was over-ripe.

Mr. George Bunyard of Maidstone exhibited fine large fruit of Dr. Jules Guyot Pear, a handsome showy Pear, but the flesh was coarse and the flavour inferior. He also showed fine specimens of Williams' Bon Chrétien and Souvenir du Congrès Pears, for which a vote of thanks was awarded. Lady Sudeley Apple, which was certificated last year under the name of Jacob's Strawberry, maintained the high opinion of it expressed by the Committee. Mr. T. Laxton of Bedford exhibited a seedling Plum called Self-Help, a cooking Plum like a large Mussel. The flesh is yellow, firm, and rather adheres to the stone. It was not considered superior to Diamond.

FLORAL COMMITTEE.—Present: Shirley Hibberd, Esq., in the chair, and Messrs. James O'Brien, H. Williams, J. Dominy, Charles Noble, G. Duffield, Thomas Baines, J. Child, J. James, W. Bealby, W. Wilks, H. Bennett, W. B. Kellock, J. Fraser, H. Turner, J. Hudson, J. Walker, and M. T. Masters. Mr. Hugh Crichton, Belleaire Gardens, Greenock, showed some specimens of the Glasgow Prize Cockscobs, one of which had a head 2 feet across from tip to tip, and over 6 inches in diameter in the centre. The strain was commended. Mr. King, Rowsham, showed several seedling Coleuses, Capt. Wetherall, crimson and maroon; and Cloth of Gold, light yellow, being the

best. Messrs. J. Carter & Co., Holborn, were adjudged a vote of thanks for a plant of *Fourcroya longeva* bearing numerous young plants upon the inflorescences, and a certificate for a *Lilium* described under that head. H. J. Buchan, Esq., Wilton House, Southampton, was accorded a cultural commendation for a well-grown plant of *Odontoglossum Krameri* with four spikes bearing about sixteen flowers. W. Soper, Esq., 307, Clapham Road, sent a plant of *Ananassa sativa variegata* neatly variegated. Messrs. J. Veitch & Sons, Chelsea, showed a plant of *Amasonia punicea* with abundant spikes of creamy flowers and bright scarlet bracts, very showy. Mr. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, was awarded a cultural commendation for an excellent specimen of *Vanda Sanderiana* with two spikes of seven and eight flowers each. Mr. P. Ladds, Swanley, sent plants of the pure white Zonal *Pelargonium White Queen Improved*, which is very free and bears large trusses. Mr. Aslett, gardener to C. Butler, Esq., Warren Wood, Hertford, had a double pink Tuberous *Begonia* named Mrs. C. Butler, very free and large flowers. Messrs. R. Veitch & Son, Exeter, showed flowering branches of *Escallonia exoniensis*, a seedling of strong habit, with large tubular pinkish white flowers, for which a vote of thanks was accorded. Messrs. W. Paul & Son had plants of *Abies Douglasi* and a variety named *glauca*, with a distinct bluish tint. This firm also sent three varieties of climbing *Roses*, one of which was certificated.

CERTIFICATED PLANTS.

Lilium auratum rubro-vittatum (J. Carter & Co.).—A bold variety with large flowers, the petals white striped in the centre with dark red.

Dracena Norwoodiensi (J. Veitch & Sons).—A graceful variety, with lance-shaped leaves about 1½ inch broad in the widest part, and tapering to each end, elegantly streaked with green, red, and white, the latter chiefly on the margin.

Lomariopsis buxifolia (J. Veitch & Sons).—A very pretty and distinct Fern of semi-scandent habit, and shown growing over a large Tree Fern stem. The fronds are pinnate, 4 to 6 inches long, with small shining green oval pinnales closely placed.

Rose Waltham Climber No. 1 (W. Paul & Son).—A pretty variety of a bright lively rose tint, and likely to be a useful autumn Rose, as it is extremely free, and the cheerful tint renders it especially acceptable.

Cactus Dahlia Mrs. C. Hawkins (T. S. Ware).—After being shown several times, this really meritorious variety has received the recognition it deserved. It is a pale yellow or cream-tinted form of the Juarezi type, and approaches that very closely in the shape of the blooms.

Gladiolus J. L. Toole (Kelway & Son).—Very handsome, rich crimson, the lower petals white at the base, flowers large, and spike massive.

Gladiolus Prince Waldemar (Kelway & Son).—Bright clear rose in colour, with white lines in lower petals. A charming variety.

Gladiolus Lord Carnarvon (Kelway & Son).—A bold flower, bright scarlet, with a white centre, which shows up the brilliant tint well.

Dahlia Mrs. G. Rawlings (Rawlings Bros.).—A Show variety, well built symmetrical bloom, white tipped with crimson purple.

Dahlia Bird of Passage (Rawlings Bros.).—A charming Show variety, bloom of moderate size, but neat form, white tipped with pale rose, the centre of the bloom being of the latter shade.

Dahlia George Paul (Rawlings Bros.).—This was certificated as a Decorative variety, and though not of first-rate form it is attractive in colour, the florets being white tipped with deep rich crimson.

Dahlia Eclipse (H. Cannell & Sons).—A single variety, rich deep scarlet, yellowish at the base, the florets round, and general outline good.

Dahlia Faust (H. Cannell & Sons).—Another single variety of a peculiar bright red shade, the florets substantial, broad and round.

HARDY FRUIT GARDEN.

GATHERING FRUIT.—We were recently dining with a gentleman who has an extensive fruit garden, of which he is justly proud, for it contains a large collection of the best sorts of fruit, and his evident vexation at finding unripe fruit had been sent in for dessert was a reminder to us of the fact that due attention is often wanting on the part of fruit-growers in gathering the fruit, which they now bring to so high a degree of excellence. Certainly we ought not to rest satisfied with anything short of absolute perfection in fruit culture in garlens—a very different affair to fruit culture in the orchards and plantations of market gardens. In the garden of a private gentleman facilities generally exist for the culture of fruit in its highest form, and the gathering of it must certainly be regarded as no mean part of such culture. Take, for example, Green Gage Plum. For culinary purposes it is sufficient if the fruit is about half ripe, but for dessert we watch each fruit with anxious care, and not one should be picked for table that is not perfect in ripeness, bloom, and colour. A pale, glossy, greenish-yellow small fruit of this delicious old Plum is not a tempting object, but a really fine fruit, covered with delicate bloom, with a pink tinge upon the side most exposed to the sun, and not unfrequently having a slight crack or two in the skin, is both grateful to the palate and tempting to the eye; and it is precisely this happy combination in fruit of entire gratification of the two keen senses of sight and taste which marks perfection. We call timely attention to this important matter now in order to secure greater watchfulness and patience in Pear gathering. It has long been our habit at this season of the year to devote an hour or two on fine afternoons to a careful inspection of the fruit, and to gather it gradually, a few from each tree, as it becomes quit

ready. Depend upon it that such care, combined with delicate handling and careful storage in the fruit room, carries its own reward with it, for it enables one to have a supply of ripe fruit in succession for a long time, and to become intimately acquainted with the peculiarities of each sort. Knight's Monarch affords a remarkable example of the importance of such care, the fruit always ripening in batches, some being ready long before others, and if the forward fruit is not picked as it becomes ready it will fall and become bruised. In looking over the fruit the eye soon becomes accustomed to the different changes of the fruit, and by lifting the fruit outwards it parts readily from the branch when ready for gathering. Do not forget that many Pears are good one year and inferior or decidedly bad another. A sort with a good character ought not, therefore, to be lightly discarded, and remember that the fruit can at the worst always be turned to account for stewing. After the fruit is picked, if the drought still continues, let every tree have enough water to thoroughly soak the soil, so as to promote a strong full flow of sap to render the buds full and plump for another season. Let us not also forget to apply the lesson of the drought once more. A dry hot season insures colour and flavour, but the fruit is always small if the trees are not watered and mulched. See, then, that the supply of water to the fruit garden is abundant enough to insure a full supply throughout the driest summer, and also that the means for its use among the trees is simple and efficient. At Chiswick the trees have had both watering and mulching this summer with the best results. Let us beg gentlemen having fruit gardens to send their gardeners to the Fruit Congress to be held there this autumn, and to impress upon gardeners the importance not only of seeing the display of fruit, but to go into the gardens among the fruit trees and to get a lesson from Mr. Barron's practice.

FRUIT FORCING.

FIGS.—*Early-forced Trees in Pots.*—The next two months may be considered the resting period of early Figs, during which they must be kept moderately dry and as cool as possible. If they persist in growing, the roots that have found their way into the fermenting bed should be cut through about a foot from the pots, and the plunging material taken out down to the bottom of the pots. All unripe fruit should be removed, and red spider kept from increasing by washing the trees occasionally with the syringe until the leaves fall, when not a day should be lost before the annual cleansing should be given. If the roof lights are moveable they may be taken off for a season if fine for painting or other repairs, but they must not be removed under any pretence unless the wood be thoroughly ripe. It is necessary, however, that any painting be done in time so as to allow of its thoroughly hardening before it becomes necessary to subject it to the trying influences of confined moisture.

Succession Houses.—The trees in these will still be ripening quantities of useful Figs, and will need a free circulation of dry warm air, the most important factor perhaps in the production of high-class fruit. When necessary to keep these trees in bearing a time longer a little fire heat with ventilation through the night will be necessary, and any watering must be given early when the day promises to be fine. Red spider will make headway with the dry heat, and brown scale is often very troublesome, and if undisturbed soon finds its way to the foliage and fruit, from which it cannot be dislodged without injury. As prevention is better than cure the parts infested should be well washed with an insecticide of approved strength with sponge or brush before these pests have time to spread. Thin out any spray that may have accumulated now, not waiting until pruning time, allowing the regular extension or succession shoots intended for next year's crop to grow up to the glass, where light and warmth will mature the points better than were they kept closely secured to the trellis.

Young Trees in Pots for Early Forcing.—Any young trees in pots still under glass and having rooted in the plunging material should have the roots cut off, as a means of inducing rest. Any that are not considered of a size fit for forcing, and will need growing on another season in heat preparatory for early work, should be shifted; and those which though large enough in head for forcing are not in the size of pot desirable should be shifted into larger pots without delay. All straggling roots should be cut off when potting, and the soil rammed very firm as the potting proceeds, otherwise the water when they are again started will pass away, the old balls become and remain dry, and the first crop of fruit will drop. Rich turfy loam with a sixth of lime rubbish and a sprinkling of bones is a proper compost. The culture of Figs in pots is a most interesting mode of culture, as many of the moderate growers can be accommodated in a small house, and, being very prolific, plenty of heat and moisture will result, along with good feeding, in the production of a full crop of delicious fruit of a highly wholesome and health-giving kind.

PINES.—Pine plants, especially Queens, which are intended to give a supply of fruit next May or June, should by this time have developed a sturdy growth, and have the pots well filled with roots. The utmost attention must be given the watering, so as to maintain the vigorous habit acquired, bearing in mind that the soil, being permeated with roots, will have parted with much of its feeding qualities, and to make up for this loss stimulants will be necessary to maintain the vigour of the plants, being careful not to give them too strong and always tepid, and every time the plants are watered. In order to secure the thorough maturation of the plants a liberal supply of air should be given whenever sunshine and heat prevail to an extent to allow of its being given, and the atmosphere must not be too closely charged with moisture; but syringing the plants should be continued two or three times a week during fine weather, or as shall be determined by an examination of the axils of the leaves of

the plants, which ought not to have the moisture there lodging exhausted. All suckers showing before the fruit makes its appearance should be removed, but when the fruit shows one should be left on for continuing the stock.

Successional Pine Plants.—Plants not so forward as the preceding, and yet required in subsequent order, should have every encouragement whilst sunshine and heat are effective, as may be expected during the present month. Fire heat should not be resorted to unless the temperature falls below 60° at night, and trap the sun heat by closing early in the afternoon, which should be done so as to enclose a temperature of 90° to 95°, when the needful moisture to insure an invigorating condition should be afforded.

Fruiting plants should have a night temperature of 70° to 75°; they will need a somewhat drier atmosphere than for those last mentioned; still, a genial condition of the atmosphere is essential where the fruit is swelling off, ventilating early and closing early. Shading should be discontinued except it be in the case of plants that have the fruits near the glass. Shading ought also to be discontinued over those plants with roots in other compartments, but suckers will, of course, need shade until rooted.

STRAWBERRIES IN POTS.—The pots of the earliest-potted plants will now be filled with roots and produce runners in quantity, requiring removal two or three times weekly, and in looking over the plants much time and labour will be saved by thinning out all plants with doubtful crowns and consigning them to the rubbish heap. It will also be necessary to determine whether the plants are to be grown with single or many crowns. The single crowns we consider the best, and those who intend to try it should remove the side ones as they appear. Give the plants plenty of room, and see that they never lack moisture. Autumn-fruited plants that have been kept in pots through the summer, and are now expanding their flowers, should be moved to cold frames, where they can be closed with a dry atmosphere at night; but avoid keeping close in damp weather, and from these they can be brought forward in warmer houses as desired. Plants that were planted out after forcing for lifting in autumn may have glass placed over them if convenient, or the plants need not be lifted until the fruit is set; but as this is not practicable in many places the plants had better be lifted just before the flowers open, and be potted into as small pots as will contain the roots. They should have shade from bright sun, and be dewed overhead occasionally to revive them, they being stood in a cold frame or pit and kept rather close; but air should be given, if only a little, the greater part of the day, and as soon as they will bear the sun they should be moved to the shelves of a house with a south aspect, where they will need the assistance of a moderate degree of warmth and a free circulation of air, as in a close moist atmosphere the pollen clogs or does not discharge freely, and badly shaped, ill-set fruit results.

PLANT HOUSES.

Crotons.—Plants that have become tall are useless for many forms of decoration, and as large heads can be rooted at this season of the year with as much ease as cuttings of a smaller size, they should be inserted at once. Large heads may be rooted without losing a single leaf if kept perfectly close under handlights or in the propagating frame in a close warm house where they can be shaded from the sun. The heads may be inserted in the centre of the pots in which they are to be used for decoration. A little sand should be placed in the centre for the base of the stem to rest upon; they will be found to root equally as well as if placed into small pots, and the labour of potting them afterwards is saved. The heads, if well coloured, should be large enough for the purpose for which they may be required without having to make fresh growth. If they start into growth after they are rooted it is questionable if they will colour sufficiently well after this date to be presentable for conspicuous positions. As soon as they are rooted they must be placed on a shelf close to the glass until well established in their pots, and then subjected to cooler treatment to prevent growth. Plants that have been prepared for this purpose in 5 or 6-inch pots, or even larger, and have completed growth, and have highly coloured foliage, must be prevented from making any further growth. Growth made after this date often spoils the beauty of the plants, for very rarely is the light and sunshine of autumn sufficient to colour them properly. Growth is easily prevented by a lower and more airy atmosphere without the slightest injury to the plants. On the contrary, this treatment hardens and prepares them wonderfully for room-decoration, where they will last double the length of time than would be the case if taken direct from a warm close structure. Plants that have not yet completed their growth should be pushed forward in brisk heat and given every ray of light possible to colour their foliage.

Stephanotis floribunda.—If these plants are to flower well another year every ray of light and sunshine possible should be admitted to them, for if the wood is not well and thoroughly matured they cannot be expected to do this. Those that have completed their growth should have, in addition to light, more air and a drier atmosphere to harden and solidify the wood they have made. Those still growing must be pushed forward in brisk heat to complete their growth as rapidly as possible, or it will not be sufficiently ripened to flower well. Many fail to flower profusely this plant because insufficient attention is paid to the ripening of the wood and preparation of the plant for the period of rest, which must follow if they are to grow luxuriantly and flower abundantly the following year.

Clerodendrons.—Every attention must be devoted to *C. Balfourianum*

and other varieties of similar growth to ripen the wood thoroughly of those required for early flowering. The whole of the stock of plants, whether growing or not, should be exposed to full sunshine, but those that have nearly completed the ripening of their wood should have more air and a drier atmosphere than those that are still growing. When the wood is ripe water may be gradually withheld in order to send the plants to rest, but this must be done gradually or the roots are liable to perish. Those still growing must be encouraged by abundant supplies of heat and weak stimulants to complete their growth as early as possible, for a much longer time will be required to thoroughly mature the wood of these plants than is the case with those started earlier into growth. Seedling plants of *C. fallax* that are well established in from 3 to 5-inch pots may be potted on, especially those in the smaller sizes. If any of them are showing signs of flowering it is useless to pot or pinch them now that the growing season has advanced so far. These and all that it is not necessary to place into larger pots should be liberally supplied with weak stimulants every time they require water. Pots 2 inches larger than those in which they are now growing will be plenty large enough. These plants do well in a compost of fibry loam, leaf mould, sand, and about one-seventh of decayed manure. Leaf mould should be used to the extent of about one-third. If any of these plants are in a backward state they should be pushed forward in brisk heat, while those already too forward may be retarded by a lower temperature; but care must be taken not to check them, or else their heads of bright scarlet flowers will only be small in comparison to what they should be when given liberal treatment. A good batch of *C. fragrans* should be rooted now in 4-inch pots, in which they should be allowed to grow and flower. This sweet double white variety flowers much more freely when confined in small pots than when given abundance of root room.

Gardenias.—The bright hot weather that we have been having has brought the earliest batch of these plants on rapidly, for flowers have already expanded with us, and well-developed buds are plentiful. The flower buds unfold quickly at this season, and if they are coming forward too fast a portion of the plants may be removed for a time to cooler quarters, which will considerably prolong the autumn supply of bloom. While in a somewhat lower temperature care should be taken to water them at their roots with tepid water, or else the roots may suffer and the late flower buds will become crippled. Stimulants must not be used too strong, for more flower buds are injured from this than any other cause. The second and later batches of plants should still remain in the heated structure in which they have been grown during the summer. A good batch of cuttings should now be rooted by inserting them singly in small pots and growing them on afterwards. These will take the place of old plants, which can be thrown away after they have done flowering. For the winter and spring supply of bloom young plants are preferable to old ones, they take up less room during a good period of the year, and are less liable to the attacks of mealy bug and scale. Cuttings rooted now and grown on through the following summer will make by autumn plants more than 2 feet through them.

Tydeas.—Such varieties as *Madame Heine* that are grown from cuttings for winter flowering should be placed at once into their flowering pots if not already done. Pots 4 and 5 inches in diameter are large enough for these plants. If they are in a backward state push them forward in brisk heat, or if too far advanced they will bear being retarded by cooler treatment without injury. These plants must not be syringed overhead, or else their foliage will be browned and injured. They do best while growing with moisture-holding material beneath them and the atmosphere moderately dry. These plants must still be lightly shaded from bright sunshine, but no more light than possible should be excluded from them.

THE BEE-KEEPER.

NOTES ON BEES.

OPEN VERSUS CLOSE DRIVING.

"A YORKSHIRE BEE-KEEPER" seems to have been unsuccessful in open driving, and desires information upon it and kindred subjects. Bees are always most easily driven when getting honey. Between 7 o'clock and 9.30 A.M. is not the best time to drive bees, but between the hours of 1 and 3 P.M. should be chosen. Open driving is not superior to close driving unless it be more favourable for catching the queen, a feat which should be performed only when the queen is to be deposed. The commotion observed about the hive after drumming was caused by robbers being attracted to the hive while inverted. When hives are being driven it should be performed indoors, unless when honey is plentiful. If bees show a disinclination to run, tie a cheesecloth over the mouth of the hive and set it in a warm place for a few minutes, they will then quickly leave the hive. The best sugar to feed with is either best loaf, granulated or crystal-

lised; if cane sugar, rather thin than thick at this season, without either salt or vinegar. Thirty pounds at least is necessary for a hive to stand the winter, and it is better to let a hive have the whole frames than contracting them too much. Cushions filled with chaff are not nearly so good for covering hives as long grass thoroughly dried, or even straw; either of the two are superior to cloths or chaff cushions.

REARING QUEENS.

"Basil" wishes for some information about raising queens. This is best and easiest done with moveable-combed hives. With straw hives a great deal of cutting comb and fitting into little frames is necessary, which cannot be carried to the same extent as with frame hives. The best hive for raising queens is the sectional hive, but it is best in the hands of an expert. To raise queens to supersede old and unfertilised ones, a good hive containing a prolific queen should be selected and pushed forward, so that swarming will take place some weeks earlier than is usual. After it has been swarmed artificially, or has done it naturally, leave it alone until the queens begin to pipe, or till about the tenth day after swarming; then have in readiness either little boxes to hold three frames or hives, having two to four entrances, with divisions between each lot of bees. In my own case I have hives which I keep for transferring frames and bees to from more bulky hives when taking to the Heather. These hives have two, and some four entrances, which open and close with a slide, and of course division boards are necessary for the number of nuclei, which is simply one frame with bees and queen cell dropped between other two frames filled with foundation. If there are not royal cells enough, two or more frames must go together. The centre combs have usually sufficient brood and bees, but the outside ones are commonly deficient of brood. These I place near the original site, thus equalising the strength of nuclei. With favourable weather the whole of the young queens in about a week or less after hatching will have commenced laying, so that plenty of young queens are now ready to take the place of queens in stocks that have swarmed, and from which a frame of brood with queen cell should be taken and given to nucleus deprived of its queen. A dozen of such nuclei will supply the wants of a large apiary during summer as well as providing young fertile queens for another season. Where purity of breed is wanted, removal to a distance from the influence of other drones is absolutely necessary.

SUPERS VERSUS SECTIONS.

At page 170 in the 20th August issue, your correspondent, "Co. Wicklow," says, "'A Lanarkshire Bee-keeper' takes great trouble to prove that bees prefer ordinary supers to sections." To that I reply that I have taken no trouble to do so. The greatest tyro in bee-keeping soon perceives that, unless it be those who do not exercise their own judgment in the matter. I am glad to see "Co. Wicklow" agrees with me that sections are a mistake, but he misses the mark entirely when he attempts to say that supers are unsaleable, while he must be very unwise who sells super honey at the same price as the contaminated honey from brood combs. All hive dealers do not sell more sections than supers; and as for the demand for supers in preference to sections, I simply gave the evidence and wants of some of the largest honey merchants in Scotland, and singular to say my inquiries were made in order to supply querists—many of them from Ireland—with the price likely to be obtained for honeycomb in sections, as it was a drug in the sister island. Your correspondent has, therefore, an opportunity of assisting his bee-keeping brethren in Ireland by making it public where merchants will give 1s. per lb. for section honey. As for myself, I have an open market for a large quantity of small supers, which I can supply, but for sections there is no demand. If "Co. Wicklow" will read my published articles he will see that I never recommended large supers unless they were divisible ones, while I have also shown that they

are cheaper and more easily prepared and sent to market than sections proper, while the fact that bees fill supers quicker is an important item in their favour.—A LANARKSHIRE BEE-KEEPER.

THE IDEAL HIVE.

"A CAMBRIDGESHIRE BEE-KEEPER" has, in an article somewhat too acrid to gain the earnest attention of men who desire to prove by argument and not by ugly innuendoes the value of the hive they champion, entirely missed the mark, and has not even touched the point at which the contest for superiority really begins. It is well perhaps that the case should be as clearly as possible put before the minds of those apiarians who are as yet undetermined in their verdict as to the value of the different systems for obtaining honey now in vogue amongst practical bee-masters.

There are, in reality, but two schools of beeists—the lovers of the moveable frame hive and the lovers of the straw skep. Now, before even entering upon the various merits and demerits of these respective systems, let us consider the real object we have in view. Is it to gain the greatest amount of honey from each stock? The answer, to my mind, is Most certainly not, and if this answer be the true one—and that it is so I shall endeavour to prove—the whole foundation upon which the article of "A Cambridgeshire Bee-keeper" is built at once collapses. What the object is may very briefly be stated, and a definition of the hive required may be concisely given as follows:—"A hive from which, with the least possible expenditure of time and money, the greatest nett profit can be obtained." What matters it if 150 lbs. can be taken from a hive if the trouble and expense is so great as at once to bring down the nett return to a sum easily realised by another hive of simpler construction, of easy management, and of a description needing a minimum of manipulation? At present, the question whether a larger amount of honey can be taken from the moveable-hive than the skep may be left unconsidered.

Let me ask a question, and let someone answer it from the notes and accounts, which are doubtless carefully kept by all, of their expenditure and of the time taken up in the varied manipulations their system requires to gain a full measure of success. How long does fixing foundation take? How long does the periodical "spreading of brood," so strongly advocated, occupy the apiarian? How long does the operation of extracting from the bars, taking sections as they are individually finished and inserting new ones, take to perform? Probably the time-honoured "few minutes," which if at the end of the manipulating season were added together, would, in even a moderately sized apiary, amount, doubtless to the surprise of the owner, not to hours only but to days and sometimes weeks. Again, the outlay or purchase of an "extractor," the continued upsetting of the domesticity of the hive, and the interference with the industry of the bees at most important periods, trifling in themselves, are of no small moment, when added to them is the danger of losing the queen or injuring her, and giving an impetus, especially in the late summer, to robbing, which is so easily started that a whole apiary may be put into a state of frenzy by even the opening of a hive, not to speak of any of these delicious manipulations. Now for a very brief summary of the skep. The outlay is small to begin with, the swarm is hived into it at once and not transferred, the material is most conservative of bee life, most inimical to damp, the place of foundation can be taken by a little extra syrup, besides the amount the bar-framists advise being given to the swarms supplied with expensive foundation. Why, for the price of foundation sufficient to give to a swarm, as generally advised, full sheets, syrup enough can be given not only to fill a paltry bar hive—ten or twelve standard frames, a size most generally in use—but to fill a large 20-inch by 12-inch Pettigrew skep, and in addition to filling it with comb give such an impetus to egg-laying as to make the hive ready to gather surplus with larger number of workers than the swarm to which foundation and a little syrup only was supplied.

"A Cambridgeshire Bee-keeper" admits the probability of swarms issuing from skeps. He means, I imagine, that the stocks are ready to swarm naturally or to be swarmed artificially at least seven days earlier than the stock in the more elaborate hive. Seven days earlier! time enough to gather, in good weather and in favourable localities, 20 lbs. of honey. He admits this I say, and yet has ejected these valuable early swarms from his apiary in favour of hives at least a week later. In some years a week is a most important time, not merely a paltry seven days of no special value. Again, is anything simpler than to swarm the Pettigrew skep? Is there any hive from which so magnificent a swarm can be taken? Does any hive lend itself more readily to supers, sections, or any other vehicles for obtaining surplus honey? Is there any hive from which more honey can be taken in addition to the surplus honey from the top? I have a fine swarm hived in an 18-inch Pettigrew from which a glass super has been taken, and the stock weighs 95 lbs., showing a prodigious amount of labour, considering that June was in my district a poor month, and that Clover was nearly over in the third week in July. But this result is but poor to what would probably have been obtained in a good season and with a May swarm. The swarm, I may say, came from a bar hive; for although a strong believer in the skep, I am not so bigoted as to eject from the apiary a hive whose merits are not perhaps sufficiently appreciated, as I have no time to spare in useless manipulation. If, then, it can be shown that after the time spent in manipulation, the extra expense incurred both on capital, outlay, and current account, a yield of honey is given by a stock managed by a bee-master of average intelligence, so great

as after paying for all these extra expenses to yield a larger nett profit is given than by the other system, then it will be time, and not till then, for these bar-frame eulogists to come and subvert the teachers of that other system by which any man, not entirely without intelligence, may help himself, by the addition of a few stocks of bees, to his garden or field. Men of genius, men who have the time and money, may possibly make a greater gross profit from these hives with all their charming adjuncts, but if they do it is of no practical use, for our object is to give to the public the idea of a hive of ideal simplicity both in construction and management, and thereby insure that success without which bee-keeping would be but a useless hobby and a pastime for the well-to-do.—**FELIX.**

FRAME HIVES v. SKEPS.

FOR some time I have endeavoured to assist and advise bee-keepers how best to act with whatever hive he possessed without running into expenses by discarding them and purchasing more expensive hives that would not give better returns. I have also shown how straw hives can be made as profitable as any frame hive, as well as the absurdity of those who published so prominently that no honey worth speaking of could be had from straw hives, or rather that "honey could be had only from frame hives." A greater mistake could not appear in print. There is an apiary near me containing all sorts of hives. The two that have given most honey this year were a straw hive and an old cheese box. I am not aware of having condemned any hive farther than pointing out those which possessed the most points favourable to bee-keeping and those that did not.

Many inexperienced bee-keepers besides your "Cambridgeshire Bee-keeper" have at first thought little of ventilating floors; none but he, however, termed them absurd, and the hundreds who now use them find them the key to successful bee-keeping, while my own experience proves them the same. Had your correspondent supplemented his sixty-four lines of condemnation with some information he would have done some good, but I observe he has had only four years' experience with frame hives, therefore cannot be expected to furnish reliable information, or had he but needed the advice to take nothing for granted, but test and prove everything, his language might have been less hostile.

I think it is quite safe for me to say that I have had more experience with frame hives than any living writer in Great Britain. My experience dates back to 1850 with these, and slightly as your correspondent speaks of what I say, there is not a frame hive made that does not possess some contrivance of my own; and, singular to say, your correspondent unwittingly pays me a high compliment when he says "It is the facility a frame hive gives for spreading brood which is one of its most valuable points." The author of that system is not Mr. Cowan, though he, like your correspondent, claimed it, but he retracted after I took him to task for what he said. The inventor of that was myself, and the second hive I made on that principle had it, but the ventilating floor is better. It has become quite fashionable of late for hive-makers to claim others' inventions. Both "A Dalbeattie" and "A Dumfriesshire Bee-keeper" claimed to be the inventor of my hive. The editor of the paper which published this suppressed my replies, but thanks to a contemporary it was exposed.

The introduction of the quilt was claimed by Abbott in the *British Bee Journal* a few years since, whereas it was fully explained in the pages of this Journal by "A Renfrewshire Bee-keeper," Mr. Langstroth, and myself more than a quarter of a century since. The Raynor queen cage, too, about the same time was explained by Mr. Alexander Ferguson, Stewarton, and "A Mauchline Bee-keeper," as well as "A Renfrewshire Bee-keeper." I was the successful introducer of comb foundation, using it largely, and urged others to it fifteen years before Abbott requested me to instruct him and speak to Mr. A. Neighbour to supply him with plates, which he did; yet, in a year after, told me they were of no use in the hands of cottagers. I put him right, and showed him the methods of fixing. Now a patent is taken out for one of my plans that was made and sold before I hit upon the better plan of grooving the bars and fixing with wax melted in a glue pot, and lifted out and poured into groove with a teaspoon. The splitting of the top bar was also my plan, claimed also by that patentee. Mr. Neighbour, too, had a plan almost similar. The objection I had to the block system was that, as it does yet, checked the foundation, making it liable to break away. Latterly I improved on it by putting in two screws, which held it firm without checking or having it liable to fall when the bar clung from the heat of the hive from the one side of the groove only being waxed. Had the patent been a better mode of fixing foundation than the groove I would have protested against the patent being granted.

"I have more crows to pluck" of a like nature, which I may take up again; but even the above I would not have mentioned had it not been to show your unprejudiced readers that what I have written carries more weight than some, including "Cambridgeshire Bee-keeper," represent. Now that I have given some information, and I am willing to give more. His one question as to which half of the hive I had the sections on, I gladly answer. It was the right half, but my hives have no wrong side. It is the sections that are wrong. If he follows my advice and arranges his supers as I explained he will get more honey, retaining the small pieces of comb; 126 lbs. of finished sections is not the maximum by nearly 100 lbs. that has been taken from a hive here. I stated why and where supers were more saleable in a recent article, and I do not wish to go over that again. So did I about the evils of spreading brood, which if attempted in many parts would be the total annihilation of bees, while no

part of Great Britain is free from low temperatures suddenly after great heat. The present year will be memorable for that; every month, so far as it has gone, having several frosty nights. Besides, my argument that bees spread themselves without any external aid, and that spreading brood does not hatch quicker, and that it is irrational to cram the bees into little space to-day then cool them down the next, has not been negated by anyone. On the contrary, I have proved myself to be correct, and my warning has been given accordingly.

Extracting honey from unsealed combs, all liquid gathered by the bees for food to their young from feculent matter, is thrown out by the extractor, mixed with the honey, and is swallowed by the unsuspecting consumer; yet this is what our modern sages teach bee-keepers to do.—**A LANARKSHIRE BEE-KEEPER.**

TRADE CATALOGUES RECEIVED.

J. Carter & Co., 237 & 238, High Holborn, London.—*Catalogue of Bulbs, Winter and Spring Flowers (illustrated).*

William Bull, King's Road, Chelsea.—*Catalogue of Bulbs.*

Smail & Co., 23, Lime Street, London, E.C.—*List of Dutch Flower Roots.*

E. G. Henderson & Son, Maida Vale, London.—*Catalogue of Dutch Bulbs.*

Hooper & Co., Covent Garden, London.—*Bulb Catalogue for 1885.*

Barr & Son, 12, King Street, Covent Garden.—*Catalogue of Bulbs and Plants.*

W. Dobbie, 62, Preston Street, Faversham.—*List of Pelargoniums and Fuchsias.*

H. Cannell & Sons, Swanley, Kent.—*Complete Book of the Best Plants to Flower all the Winter (illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

National Auricula Society (R. C.).—There are two sections of this Society—the Northern and Southern sections. The Hon. Secretary of the latter is Mr. J. Douglas, The Gardens, Great Gearies, Ilford, Essex, from whom you can obtain all particulars.

Iberis coriacea (C. R.).—The above-named plant is a hybrid between *I. sempervirens* and *I. saxatilis*, as stated on page 176; but your confusion is probably caused by the fact that the last-named plant, *I. saxatilis*, is usually regarded as synonymous with *I. corifolia*, of which a figure was given on page 177. This, however, is quite distinct from *I. sempervirens*.

Fertilising Cereals (W. J.).—Grasses can be artificially fertilised in the same way as other plants—namely, by transferring the pollen from the flowers of one variety to those of another, and it is to experiments of this kind that the letter noted by you refers. In some Grasses and other plants the anthers are mature and discharge the pollen before the stigmas are ready, or in other cases the stigmas reach maturity first, and this necessitates a careful examination before fertilising is attempted.

Seedling Viola (E. C.).—The flowers were very much withered. We could see sufficient, however, of one of them to observe that it was attractive, but whether distinct from all others or not it is impossible for us to say. Send a flower to Mr. William Dean of Walsall, enclosing a stamped envelope for reply. He will perhaps compare it with others in his large collection and favour you with a reply.

Vines Infested with Thrips (P. S.).—You can eradicate the thrips from your vinery by fumigating the house with tobacco smoke. Two, three, or even more applications will be necessary to accomplish this, for unless the house is well filled with smoke it will not destroy the eggs. The smokings should be done on successive evenings during calm weather, and in the space of a week, if you still find living insects, it must be repeated. Do not have the house too full of smoke, for it is always better to fumigate two or three times than to give one strong smoking, which is very liable to injure the foliage of the Vines. If you do the fumigating carefully you may destroy the thrips without injury to the Vines or the fruit.

Fungus on Vines (C. H. Contich).—Several of the leaves sent are in-

festated with the black fungus, the mycelium of which is spreading over the surface. Sponging them with a solution of soft soap, then while wet dusting with sulphur, allowing it to remain on for some days, is the only remedy we can suggest that can be safely applied. The Vines have not had good attention, for some of the leaves are warted and the others scorched. The house has been closed when it ought to have been open, and a genial bnoyant atmosphere has not been maintained. This faulty management we consider the real cause of the fungus attack, there having been an extravasation of sap, on which the fungus has taken possession; also, if the leaves sent are a fair sample, the Vines are lacking in vigour, and much stouter and larger foliage is essential for the production of first-class Grapes.

A Sussex Plum (R. N.).—We have no doubt that the Plum to which you refer is the Victoria, an extremely prolific and useful variety. It is thus described in the "Fruit Manual":—"Victoria (Alderton; Denyer's Victoria; Sharp's Emperor).—Fruit large; roundish oval, marked with a shallow suture. Skin bright red on the side next the sun, but pale red on the shaded side, and covered with thin bloom. Stalk three-quarters of an inch long, stout. Flesh yellow, very juicy, sweet, and pleasantly flavoured, separating from the stone. A culinary Plum; ripe in the beginning and middle of September. The tree is an immense bearer, and ought to find a place in every garden, however small. Young shoots, downy. This is a Sussex Plum, and was discovered in a garden at Alderton in that county. It became known as Sharp's Emperor, and was ultimately sold by a nurseryman named Denyer, at Brixton, near London, at a high price as a new variety under the name of Denyer's Victoria, in the year 1844."

The Pear Tree Slug (W. W.).—The best remedy for this troublesome pest is to dust the trees frequently with quicklime; perhaps the cause of your non-success is not using sufficient at a dressing. You will find figures of the larvæ and perfect insect in the Journal, page 22, July 6th, 1882. In reference to this insect, Curtis—under the head of "Tenthredo adumbrata"—says, "Arboriculturists are familiar with a slimy black larva like a little leech which appears as if glued to the leaves of Pear trees, and which is of very common occurrence in fruit gardens in September and October. From its form and appearance Réaumur called it the slug-worm. At the end of autumn, when it has attained its full size, it somewhat resembles a small tadpole. It has twenty feet, which, however, cannot be seen without dislodging it from the leaf. It does not begin at the edges of the Pear leaf, but gnaws away the parenchyma in the middle, leaving the smallest veins and the epidermis of the under side untouched, so that the leaves attacked are left like the finest lace. After four times casting its skin it changes to an orange-yellow colour, comes down from the tree, and forms a cocoon from particles of soil bound together by a few silken threads. The perfect insect, according to Hartig, is $2\frac{1}{2}$ lines long, smooth, black, and shining, with the horns almost as long as the abdomen; the legs are black, the joints and thighs reddish-brown, the wings obscure." The grub is frequently very destructive to wall trees. It appears on Pear trees when the fruit are from one-half to two-thirds of their full size, and by destroying the parenchyma of the leaves it prevents the elaboration of the sap, brings growth to a standstill, and the Pears, instead of swelling, drop. Some authors consider that the slug-worm of Réaumur produces the *Tenthredo Cerasi* of Linnaeus; others consider it to belong to the *Tenthredo Æthiops* of Fabricius. The investigations of Gorsky, Westwood, and M. Delacour have set the question at rest. They have shown that there are several slug-like grubs which are developed into insects belonging to distinct species, and that the *T. Cerasi* of Linnaeus does not form its cocoon in the ground, but amongst the leaves of the Cherry.

Frames for Florists' Flowers (R. T.).—Brick pits about 6 feet wide, 1 foot high in front, and 2 feet high at the back, are valuable adjuncts to any garden, not only for preserving comparatively hardy plants in the winter, but for growing more tender plants in, also such crops as Cucumbers in the summer. Such plants as Carnations, Pansies, Phloxes, Chrysanthemums, and various others, including Auriculas, may be safely wintered in such pits, the plants, except those last named, being grown in the open air during the summer. We should not have any concrete bottoms, but should have the foundations of the brickwork 18 inches or more below the ground level, and fill in with rubble to the requisite height, surfacing it with coal ashes. The water would then pass away freely, and the pots could, if necessary, be partially plunged in the ashes, and thus their roots would be protected. In the summer the pits could be deepened so as to accommodate taller plants or crops. The pits should face the south. For Auriculas moveable frames should also be provided, as a southern aspect, except in winter, is unsuitable for these plants. In the summer Auriculas require a very cool position, such as the north side of a building, while in the spring an easterly or southerly aspect is preferable, except when the flowers commence expanding, when the plants must be placed in the shaded position. The plants, except in summer, are best placed on stages of wood, which can be readily formed in the frames, and the plants should be close to the glass. We should thus have both pits and frames, having ashes in the former, placing a few boards on the ashes if any plants required a dry base at any time, and wood shelves in the frames for the Auriculas. We do not know of any special mode of obtaining plants. Private growers frequently exchange plants, but do not usually sell them below their current value.

Various (E. M. K.).—If the shoot of your Hydrangea that is layered is young, not more than half-ripened wood, it will not be long before it forms roots, and can be taken off and placed into a small pot. The best way to increase these plants is by half-ripened cuttings. If you insert some at once in sandy loam and place them under a handlight, keeping them airtight in your house or in a shady place outside, they will be well rooted in about three weeks. They will root the quickest in your house, but must be shaded from the sun. After they are rooted gradually harden them to cool treatment and keep them cool through the winter. In spring transfer them from the small pots into others 5 inches in diameter. You may grow them cool afterwards or gently force them into flower—that is, if flower buds are already formed in the shoots, which should be the case if your plants have been properly treated. Grow the old plants outside until the approach of frost, when they may be taken into your house. Give liberal supplies of water and weak stimulants if their pots are full of roots. Cytisuses are pro-

pagated by cuttings, which will root freely enough at this season of the year. Fill a well-drained 6 or 8-inch pot with equal portions of peat and sand to within half an inch of the rim. The remaining portion to the rim should be filled with clean silver sand. The cuttings should be about 3 inches in length, and the foliage should be removed from the lower half. After the cuttings are made they can be inserted thickly together, well watered, and then covered with a bellglass to keep them airtight. The pot containing the cuttings should either be placed in a cold frame or shaded from the sun in one corner of your house, where they should remain until they are rooted, only removing the glass when water is required. *Vallota purpurea* will do very well outside until the approach of frost, when they should be housed and kept cool through the winter. If your bulbs are strong they will show flower before long, if they are not already doing so. While flowering you may remove them indoors if you wish. During the winter keep them on the dry side at their roots, giving only sufficient water to keep the foliage and their bulbs healthy. The plant mentioned in your fourth question we do not know by the name you give. You can only prevent the Vines covering the roof by thinning them out liberally, reducing the spurs in number, and some of the canes if the former does not prove sufficient. Without you can insure plenty of light Roses will not do well with you. We fear you will not attain much success in growing the two together on the same roof. The Roses will require liberal and constant syringing to keep them clean, and this will not suit the Vines after the fruit is set if you allow them to carry any.

Names of Fruit (Pomo).—Calebasse of foreign growth. (*Jabez Jackson*).—We believe your Pear to be Williams' Bon Chrétien. (*G. Snow*).—The Pears are—No. 1, British Queen; 2, not known. Apple No. 3 is Yellow Ingestre; 4, not known. Plum Jefferson, Grape Black Hamburg.

Names of Plants.—We only undertake to name species of plants, nor varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*X. Y. Z.*).—The fungus is *Phlyctospora fusca* of Corda, which some regard as a form of *Scleroderma* geaster, *Fr.* (*R. C. D.*).—*Neottia spiralis*, an Orchid found wild in many parts of England.

COVENT GARDEN MARKET.—SEPTEMBER 9TH.

TRADE heavy this week, with prices giving way.

THE CLERGYMAN'S FARM.

(Continued from page 218.)

In laying down land to permanent pasture, the selection of seed must be of even more importance than the careful preparation of the seed bed, for it is obvious that without good seed of the best sorts our efforts to obtain a really first-class pasture will be defeated, and we ought not to be satisfied with anything but the best. No special effort is requisite to obtain it, but it is highly important that a farmer should know which are the best sorts of Grasses and other plants for this purpose. A mere knowledge of names will not satisfy an earnest intelligent man. He will want to know

the plants individually, and to judge for himself of their comparative value. Nor is it difficult to do this if only we would devote a little space for trial plots, and we submit that if this were done on every farm to test not only forage plants, but cereals, roots, and all other plants of the farm, the knowledge gained would prove highly valuable to farmers individually and collectively. Without it a man may think he is doing well if he can maintain four or five sheep upon an acre of grass; with it he is not content unless he can keep well fully double the number of sheep upon an acre. Can anything show more clearly the difference between knowledge and ignorance than this fact? We are all wont to exclaim about hard times, to deplore the hardships of foreign competition; but do we do all that is possible to "meet the times?" Surely, if by superior cultivation of the soil and careful selection of plants we can double our profits, every sensible man will try and do so.

Let us now see what is known about plants for permanent pasture by those who have given full attention to the matter. Before all things we must have Grasses which are known to be nutritious as well as palatable. Of these the best are Cocksfoot (*Dactylis glomerata*), Timothy (*Phleum pratense*), Meadow Foxtail (*Alopecurus pratensis*), Meadow Fescue (*Festuca pratensis*), and Tall Fescue (*Festuca elatior*). These fine sorts of Grass are indispensable, and it has been said of them that sown in mixture they alone supply favourite and nutritious food throughout the year. Meadow Foxtail is of especial value for its early growth. Cocksfoot, however, takes the leading place, because it will grow in any soil, produces the greatest bulk of food, is so sturdy and robust that it suffers little from extremes of weather, is the most nutritious Grass, is eaten greedily by sheep and cattle in all stages of growth, and after the mowing for hay it makes quicker growth than any other Grass. Timothy follows Meadow Foxtail closely in spring, giving a free strong growth, and it continues to afford plenty of "keep" throughout summer. Both the Fescues mentioned are of strong growth, which is much liked by sheep; and the stronger growing of the two, Tall Fescue, answers well in wet heavy soils. Now, these five Grasses have been objected to on the score of coarseness, but it has been proved by chemical examination and by experiments in feeding, that they are as nutritious as they are productive. The finer Grasses used in mixture with them are Crested Dogtail (*Cynosurus cristatus*), Sheep's Fescue (*Festuca ovina*), Hard Fescue (*Festuca duriuscula*), Golden Oat Grass (*Avena flavescens*). Fiorin (*Agrostis stolonifera*) is also frequently recommended, but we never use it, owing to the fact of ergot being so frequently introduced into pastures among its seed, and it is beyond dispute that ergot is often the cause of abortion in cows. We are glad to find that general attention is being called to ergot in pastures as a source of abortion—many a so-called mysterious case being traceable to it.

A moderate proportion of Clovers is mixed with the Grasses. Perennial Red Clover, White Dutch Clover, Alsike Clover, Trefoil or Nonsuch, in some places indigenous to the soil, and it is one of our best fodder plants, Yarrow. Taking 41 lbs. as a sufficient quantity of seed for sowing an acre, we may safely apportion it in the following manner: Cocksfoot 10 lbs., Timothy 5 lbs., Foxtail 5 lbs., Meadow Fescue 5 lbs., Tall Fescue 5 lbs., Crested Dogtail 2 lbs., Sheep's Fescue 1 lb., Hard Fescue 1 lb., Golden Oat Grass 1 lb., Perennial Red Clover 1 lb., White Dutch Clover, 1½ lb., Alsike Clover 1 lb., Nonsuch 1½ lb., Yarrow 1 lb. As an example of the common ignorance which prevails about our best fodder plants we may mention the fact of having been asked to tell how to eradicate Nonsuch from pasture where it was regarded as a pest during the past summer.

Very earnestly do we beg our readers to give the attention to this matter which its importance demands, and of which it is undoubtedly worthy. The limited area of permanent pasture upon the clergyman's farm is all the more reason why it should be as good as possible. We do not advocate specula-

tive or ultra scientific farming, but we certainly do urge the importance of closer attention to the teaching of results obtained by the patient and costly experiments of such men as Mr. C. De Laune Faunce De Laune, who has so generously placed at our disposal the invaluable results of years of careful trials in laying down land in pasture, and close observation of Grasses. Experience has shown that in very many instances the seed mixtures brought into the market for permanent pastures are worthless, and the consulting botanist of the Royal Agricultural Society said long ago, "I am satisfied that the annual loss to the country (necessarily implying a loss to the farmer) is very great from sowing bad Grasses and worthless seed of good Grasses. It would effect a great improvement if cultivators were to discontinue using prepared mixtures and purchase the Grasses they propose to sow in the proper proportions, and mix them themselves."

(To be continued.)

WORK ON THE HOME FARM.

Now that harvest is almost finished we have seriously to take autumn work in hand, and in doing this let us keep practical utility well to the fore. The land is dry; the crops are cleared from the greater part of it; the weather is fine—ergo, if the land is foul, clean it. Leave no stubbles alone till spring if you can help it; but before all things get them clean, and any not required for winter corn or green crops or other special purposes may be sown with white Mustard, to be eaten off or ploughed in at any time. This course is sound practice, but the advice being given this autumn to leave stubbles alone and let them pass through winter foul with weeds, because the roots will retain nitrogen in the soil, is not. By all means let us apply science to farming, but do let us have common sense with it. We are giving particular attention now to arrangements for sowing green crops for sheep-feeding next spring. *Trifolium incarnatum* will be sown very soon upon clean unploughed stubbles and simply harrowed in. Rye comes next upon land that is ploughed and is well drained and fertile. Unfortunately we must sow some upon poor land, and shall have to give it a half dressing of artificial manure. This crop will be highly valuable for sheep as well as for horses, cows, and store cattle. Our primary object just now is to make ample provision for the large flock of sheep on the home farm, but we may remind every home farmer of the importance of an early cut of Rye for the dairy cows in any case, but especially if the drought has seriously affected the Cabbage crop. Next in order of sowing come winter Oats, for which the last week of the month will be soon enough; and remember, this corn crop may be of great service in spring as a green crop for the sheep. It is one of the farmer's safety valves, and he ought always to be able to use it for grazing if he wants it—if not, he has simply to leave it alone, with the pleasant assurance that he will have an early crop of corn ready for harvest by the middle of July. Let not beginners make a mistake and sow spring Oats. The tawny or winter Oat is very hardy, and is uninjured by cold, to which spring Oats frequently succumb. In October we sow winter Tares, our object being to get them well above the surface with a short sturdy growth before winter sets in, so as to have them ready for an early strong growth in spring. If sown too early they become so tall as to suffer from excessive cold, and the crop is either spoilt or lost outright. One sowing of winter Tares is obviously enough, and it is in spring and early summer that sowings of successional crops are made. Bearing in mind the great utility of winter Tares, especially in a late spring like we had this year, it will be well to make a careful calculation of our probable requirements, and let that be our guide as to the extent of land to be sown with this crop.

REMARKS.

30th.—Generally fine, but cloudy after noon.
31st.—Foggy early, cloudy morning, rain 10.15 A.M., and at intervals during remainder of day.
1st.—Fine, but not much bright sunshine.
2nd.—Fair early; cloudy, with showers in morning; wet afternoon.
3rd.—Fine bright day.
4th.—Wet and thick till 10 A.M., then fine and bright, but two slight showers in afternoon.
5th.—Fine and bright, with slight showers till 2.10 P.M., when heavy rain came on; fine after.
Temperature again slightly below the average, the nights of August 31st, September 1st and September 1st and 2nd being cold, almost a frost on the grass.—G. J. SIMONS.

RENOVATING OLD FRUIT TREES.

THE interesting "Notes on Fruit and Fruit Trees" by "A Kentish Gardener," at page 198, reminded me that there must be thousands of fruit trees which are in an unfruitful condition, and which would be benefited by a timely and judicious manipulation of root and branch. Unfruitfulness and debility are brought about through various causes, which are generally under the control of a gardener. In many gardens there are numerous Apple and Pear trees in the same condition in having too many fruit buds as those described by "A Kentish Gardener." Young gardeners may think that I am not writing very seriously when I say this, but it only applies to those trees which make little or no wood growth; and in nine cases out of ten very few fruits set on those trees, although they may have flowered profusely, and climatic influences were in their favour. The cause of this is a want of vigour; and the best way to improve them is to thin the spurs and fruit buds where too thickly placed, also removing the surface soil from the roots, baring them as much as possible, substituting for the soil a thorough dressing of equal parts of farmyard manure, wood ashes, and good loam; with a moderate addition of old lime rubbish. This we have found by experience imparts vigour to such trees, and so causes them to perfect good crops of fruit.

Old trees, either bush-trained, pyramids, or those trained to walls, which have hitherto perfected fair crops of fruit, but are now becoming less satisfactory, may have fresh life imparted to them by being subjected to the same process. Old Pear trees horizontally trained to walls are often seen with very old spurs attached to them; and although a good number of fruits may be secured, they are invariably small and much deformed. The means generally resorted to to bring these old trees into a fruitful condition beyond giving a good dressing to the roots, is to reduce the number of spurs a few at a time, sawing or cutting them off about an inch from the main stem. When fresh shoots are produced they are managed so as to form fruiting spurs. One of the best methods for bringing these old trees into a fruitful condition is to remove every alternate branch, and train fresh shoots 15 inches apart in an oblique direction from the spurs of the remaining branches; or if the spurs have been cut back, train in the young shoots. These young shoots become studded with fruit buds, and eventually form healthy fruiting spurs. We have known very old trees produce large crops of fruit when treated in the above manner.

Old cordon-trained trees of Apples or Pears may be kept in good health for years if the roots receive proper attention, and are not overcropped or otherwise ill-managed. To keep them in continuous good health they should receive a dressing annually, removing as much of the surface soil as possible. If the trees ever show signs of exhaustion a trench should be dug 3 or 4 feet from the wall, and the old soil worked carefully from the roots without disturbing those

within 18 inches of the stem more than can be helped. Before the soil is returned it should receive the addition of some good loam, wood ashes, and old mortar rubbish. If good loam is not at command turf-parings may be added. The best time to carry out the above instructions is immediately after the fall of the leaf.

Well-managed orchards of standard trees on grass are very profitable, but too often they are sadly neglected. It is true that orchard standards do not require much pruning, but they should not be allowed to grow into a tangled mass, the centre of the tree being well thinned to admit light and air to the branches. Unless the trees are well protected and the lower branches out of reach of horses or cows should not be allowed in the orchard, but sheep could be admitted, as they would enrich the ground and keep the grass down. A good dressing of farmyard manure given annually just after the fruit is gathered will prove very beneficial.—A. YOUNG.

ROSES AT SHEFFIELD.

THOSE readers whose knowledge of Sheffield is confined to the glimpse obtained in passing through the town by rail will doubtless smile at the prospect of the queen of flowers reigning in the neighbourhood of such an uncongenial atmosphere of noxious gases and smoke. Rose-growing in and around Sheffield has often been deprecated, nevertheless hundreds of good Roses that would not disgrace the exhibition table are yearly grown, and the rosarians of Sheffield are as deeply interested in Rose culture as their brethren who are in most favoured districts. A brief description of the collection of Roses at Highbury, the residence of D. Gilmour, junr., Esq., of Sandgate, may be both interesting and instructive. It is situated in the western suburbs of Sheffield and about four miles from the centre of the town, and five miles from the forest of tall chimney shafts that indicate the manufacturing part of the town and fill the atmosphere with dense clouds of heavy smoke, from which falls an unceasing shower of sooty particles, or "blacks" as they are frequently called.

The collection contains more than 3000 plants, and is the largest in the district belonging to an amateur; 2000 plants are devoted to the growth of blooms suitable for exhibition purposes. The beds, many of which are on the lawn, are wide enough for two rows of plants, and contain from twelve to thirty in each bed. One variety only is planted in a bed; the effect of the masses of different shades and colours produced by this arrangement being very striking. Borders about 4 feet wide, in which the Roses are planted in rows, occupy other portions of the ground. The plants this season, with a few exceptions, have produced a large number of fine blooms, and being full of vigour will continue to furnish a supply of good flowers until cut down by frost or spoiled by rough weather. Some good varieties that do well in many localities are not suitable for this district; those that do not succeed are, after a fair trial, discarded for some more suitable variety. The Duke of Edinburgh is an example, being subject to mildew no matter what care and attention is bestowed upon it; another is the Comtesse de Serenye, which produces large trusses of fine firm buds, but they do not open properly, and this variety will doubtless after this season be discarded. Star of Waltham is also inferior when grown here. Baroness de Rothschild, Senateur Vaisse, Fisher Holmes, Charles Lefebvre, Marie Baumann, Francois Michelin, Sir Garnet Wolseley, Duchess of Bedford, Charles Darwin, Horace Vernet, and Etienne Levat are amongst the varieties that have done the best this season. A. K. Williams have also done well, but has not yet been tested as to hardiness sufficiently to be at present recommended for similar districts; but probably the best Rose this season is Madame Alphonse Lavallée, which has done very well, the blooms being good with strong petals, very enduring in a cut state—an excellent recommendation when required for exhibition purposes. La France is extensively grown, and its rich satiny rose-coloured blooms have been gathered in hundreds. A row of about 200 plants bordering the path in the shrubbery were planted four years ago by Mr. Gilmour, and have produced each season an abundance of fine flowers, and on the occasion of a recent visit were still in full bloom. This variety is, however, likely to give way to some extent to Baroness Rothschild, which produces blooms more adapted for exhibition purposes. Several standard trees of Gloire de Dijon also occupy a position in the shrubbery, and they bloom freely each year, although they are never manured and to a certain extent left to shift for themselves.

Mr. Gilmour is a most enthusiastic and thoroughly practical cultivator, who commenced Rose culture under many drawbacks and difficulties. The natural soil of his grounds was first submitted to a competent analyst, who pronounced it sterile. To grow Roses with any degree of success it was therefore necessary to alter its character, and by the addition of suitable materials to make it rich and fertile. To do this the soil in the beds was dug out 2 feet deep and the bottom filled up about 9 inches with clay, upon which a layer of good manure was placed, and then filled up with loam, decayed stable manure, and a little clay, well incorporated together. In due time the Roses were planted and have continued to grow and bloom successfully.

About the first week in April pruning is commenced; if done earlier the late spring frosts, which are sometimes very severe in this neighbourhood, would cut down the new growths. Well-decayed stable manure is freely applied, and in addition Beeson's bone manure, nitrate of soda and night soil (from an earth closet) are also judiciously used. When the flower buds are set liquid food is supplied, prepared from stable droppings and night soil, &c. When the season is over and the wood sufficiently matured, all weak growths and strong sappy shoots are cut out and the beds heavily mulched with stable litter as a protection from the frosts, which sometimes destroy all the exposed wood. The plants devoted to exhibition purposes have all growths but three of the strongest removed in September, and these are cut down in spring to three or four buds.

Briars are the best stocks for this locality. The Manetti has been tried, but is not so suitable as the briar. The Briar stocks are raised from seed and budded as soon as they are of sufficient strength. The grounds are sloping with a southern aspect, but are exposed to the S.W. and N.E. winds that frequently sweep down from the moorlands a few miles distant with sufficient force to make Highbury (a strong well-built stone residence) rock perceptibly. The Roses have on such occasions a rough time of it and fare badly.

A "Rose Bazaar" was held in Sheffield last July in aid of the Children's Hospital, on which occasion Mr. Gilmour contributed 2000 blooms, many of exhibition quality—a large number to be cut from one collection in a single day, and furnishes an example of the abundant supply that is yearly produced. On the occasion of the visit (late in August) previously alluded to there was no lack of Roses, many very good specimens, but the litter made by the falling petals was not nearly so great as it had been earlier in the season.

Tea Roses in pots are also well grown, and in early spring the greenhouses are stocked with a choice collection in excellent health, bearing a profusion of delicately perfumed blooms. Mr. Gilmour's love of the Rose is shared by his gardener, Mr. E. Holland, who is equally desirous to excel in its culture, and ably carries out the wishes and instructions of his employer, and in four years he has carried off thirty-one first and nine second prizes for Roses, obtained chiefly in open class competition. At many of our local flower shows cut Roses, not for competition, from Mr. Gilmour's collection have been greatly admired for their size and beauty.

Although the Rose reigns supreme she does not (and never should) exclude all other plants. Lilioms occupy a position both in the greenhouse and the open border. A batch of the noble *L. auratum* is producing a number of fine blooms of varied tints and markings. A fine pot of *L. rubrum* has just bloomed, the colour of the petals being very dark and heavily marked. *L. longiflorum*, *L. Harrisii*, *L. tigrinum* (double and single), and others make up a good collection.

After a fair trial the following Roses have all done well and can be recommended for cultivation in similar localities and under similar conditions, and may serve as a guide to those who have neither the time nor convenience to experiment on so large a scale. No Rose should be hastily condemned because it does not succeed in a certain locality; what fails in one district may be very successful in another. In reading these notes it is therefore necessary that the circumstances and conditions under which the Roses are grown should be borne in mind. Baroness de Rothschild, Charles Darwin, Charles Lefebvre, Baron Nathaniel de Rothschild, Countess of Rosebery, Dr. Andry, Duchess of Bedford, Duke of Teck, Dupuy Jamain, Etienne Levet, Mons. E. Y. Teas, Fisher Holmes, François Levet, Harrison Weir, La France, Louis Van Houtte, Madame Eugène Verdier, Madame Noman, Mdlle. Annie Wood, Marquise de Castellane, Marie Baumann, Merveille de Lyon, Mrs. Jowitt, Princess Beatrice, Pierre Notting, Horace Vernet, Senateur Vaisse, Sir Garnet Wolseley, Xavier Olibo, and Madame Alphonse Lavallée. Those not fully acquainted with the above varieties may readily

obtain a full description by consulting the catalogue of any grower who advertises in the Journal.—J. H. S.

SOME THOUGHTS AND SUGGESTIONS ON FRUIT AND FRUIT-GROWING.

[A Lecture delivered at Wrexham, Friday, September 11th, 1885, before the North Wales and Border Counties Pomological Society, by Mr. E. J. Baillie, F.L.S.]

POMOLOGY is a wide subject—quite wide enough at any rate to afford ample scope for much more than an evening's talk, and yet I may ask to be permitted to travel even beyond the lines which might fairly be regarded as its limits. My excuse for this would be found in the fact that your society is young, and that before we go into matters of more minute detail which can be rightly introduced if we treated Pomology as a science, it is necessary to look at the question of fruits and fruit-growing in its aspects, varied and interesting, before cutting up our work into sections.

The word "fruit" deserves at least more than passing attention. It is a word often narrowed in its meaning and misunderstood in application. The very derivation of the word is most interesting and suggestive. It is from the word *fructus*, meaning "enjoyment." There is surely a text for moralising here. Rightly appreciated there is here a wide field for suggestiveness. There is in the occupation of fruit-growing all the elements for a life of enjoyment. It is not my intention to refer to poets or moralists to enforce the fact that gardening is among the purest of human pleasures and the most healthful of occupations. The voice of Scripture, of philosophy, of every form of literature in all periods of this earth's history, proclaims the praise of gardens. Fruit has been defined as "whatever is produced for the enjoyment of man or animals by the process of vegetable growth." It is that part of plants which contains the seed. Every seed vessel is a fruit in the language of science. But we have to consider to-night those products of the vegetable kingdom more popularly associated with the everyday idea of fruit, and yet I want to bring under your notice some items which have hitherto been neglected, and have as yet had no place assigned to them in the catalogue of cultivated produce.

From a purely commercial point of view the question of fruit cultivation is one of serious national importance. I need not remind you in what high quarters the subject has found favour. The Ex-Prime Minister, our neighbor, Mr. Gladstone, has more than once discoursed upon the toothsome compound, British jam, and the question is rapidly pressing to the immediate forefront of political, scientific, and commercial economy. In 1883, according to the statistical sheet of agricultural returns, 190,710 acres were under fruit cultivation in the United Kingdom. In 1884 the acreage had increased to 194,723 acres, or an increase, in a single year, of over 4000 acres. We may presume that the returns, when made up for the present year, may reveal the fact that we have about 200,000 acres covered with fruit trees and fruit-bearing plants. So much for its bearing upon the land and labour question. Let us see how the question of finance is affected. In 1882 we paid over two millions of money for the importation of foreign fruit. Just think for a moment what that means. What an enormous saving could be effected if much or most of this could be distributed amongst the home growers, to be expended in home industries. The absolute money value is enormous, but think what it represents in healthful occupation, in useful labour, and in happy life. Then if the habit of fruit-eating could be induced—that is, the habit of regarding fruit as a staple article of diet for the people, these figures would be enormously increased at the expense of the importation of foreign meats, and to the benefit of all concerned both in mind, body, and estate. Do not think there is any danger of the thing being overdone. There is practically unlimited room for development now, to say nothing of the ever-widening area which will open out as the dietetic errors of the people are exposed, and the rising generation are educated to the advantages secured by a life made very much worth living by regarding the rules of health, and by the cultivation of simplicity of tastes, frugality, and thrift.

Dr. Robertson of Errol in Perthshire read a paper some months ago before the Perthshire Society of Natural Science, in which he dealt with some facts presented in the fruit-growing district of the Carse of Gowrie. Dr. Robertson is an enthusiast in the matter, and it is not surprising that his neighbours have been fired by the force of his example. Enthusiasm is happily contagious, but it is seldom epidemic. The Doctor explains how the district was a noted one at one time, but its glory had departed, and it is only within comparatively recent times that a new era seems to show evidence of approach. One gentleman in the district netted £200 in one year from 7000 Gooseberry

bushes, whilst some few years ago 1700 bushes had, on an average yielded as much as 2s. worth of fruit upon each bush. According to Mr. Charles Whitehead, the crop of Gooseberries in 1883 produced something like £75 per acre, and in 1882 fully £100 per acre. I do not know what the produce would yield in Gooseberry-growing districts this year, but when I was in Cambridgeshire in the summer the trees of the fruit farms in that county were literally loaded, and the growers were making good prices.

To come nearer home to this western side of the island let us have some particulars of the Gloucester fruit farm of Lord Sudeley. His Lordship's home farm, near Toddington, was some few years ago an ordinary arable farm, for which nobody could be found willing to offer the previous rent of £1 per acre. His Lordship drained and levelled the ground, planted hedges for shelter, and Plum trees, 6 feet standards, three years old from a nursery, and which had been started in advance of the experiment, were planted in rows of 15 feet apart. Raspberries, Currants, and Gooseberries were interspersed in carefully arranged order, so that straight and uninterrupted vistas open in every direction. His Lordship had about 40,000 Plum trees, and these were all most carefully staked. Sometimes over 300 workers are employed in weeding, picking, and packing. The farm is surrounded by a fence of Canadian Poplars, planted a yard apart, and when the trunks meet and the tops are pollarded at 18 to 20 feet above the ground level, a remarkable natural wall will be formed. Mr. Beach's jam factory is established upon the premises, and some idea of the extent of the business carried on may be gathered from the fact that the bottles used in a year cost about £1000. The setting of the fruit is assisted by bees visiting the blossoms, and an apiary of 165 hives is maintained under the care of an experienced manager. That does not look like failure.

Added to this the land laws are now favourable, so that there should really be little or no hindrance to enterprise. Every place is fitted to grow fruit of some sort. That I believe is an established certainty, the doubts of the desponding being but groundless alarm. We must not be discouraged by adverse comments of the horticultural or the general press. Writers are influenced unduly by the appearances of the moment, but the experience of years shows that Nature is always mightier in repair than she is terrible in ravage. We have been repeatedly told, for instance, that Cheshire is not suitable for fruit-growing. That is only a half truth. I visited a few days ago a Cheshire fruit farm, a brief account of which appears in the *Journal of Horticulture*. Anyone filled with doubt or fear for fruit-farming in this district has but to pay a visit to this farm, he will there find abundant evidence to satisfy him that we can grow Apples, Pears, and Plums, as well as cheese.

THE STRAWBERRY.

But we must hurry on to the consideration of some more practical points connected with our subject. First, then, let us consider briefly some phases of the question bearing upon the cultivation and production of small fruits. The extent of Strawberry cultivation is something enormous. I read recently that Messrs. Vinson, who are large Strawberry growers in the county of Kent, are reckoned to grow 500 acres of Strawberries, and pick probably something like 1000 tons. It is not an uncommon sight, I believe, to see ten or a dozen railway vans loading fruits for the northern markets. Messrs. Vinson employ something like 300 pickers resident in their own district, whilst they employ about 1000 altogether. In gathering time the pickers live in tents set up round the sides of the fields, and the delights of the situation may be better imagined than described.

In the *Field* newspaper of August 15th last I observed a letter from Mr. Walter Kruse of Maidstone, giving some particulars of his system of "surface culture in fruit farming." In the course of that letter he remarks, "Since your reporter was here we have completed gathering our Strawberry crop, which has much exceeded our expectations, and has truly been an extraordinary one. Last year we had what we considered the very good crop, considering the very dry season, of over 5½ tons from about 2½ acres, or nearly 2 tons per acre. This year, after grubbing up half an acre of plants, we gathered over 9½ tons, or nearly 4 tons per acre." At market price you may readily find out what Mr. Kruse has realised. He remarks that he found the variety Sir Joseph Paxton the best adapted for market purposes. This, I have no doubt, is a correct judgment, as the fruit of this variety is shapely, firm, and solid, and if gathered dry it may be kept for a day or two, not only undamaged but improved in quality. The Strawberry is one of the most valuable of our British fruits; sub-acid, juicy, and cooling, its value medicinally can hardly be over-rated.

The cultivation is simple and the plant in every way productive. Plants should be placed out during August or September, the season being determined by the weather. This year, for instance, runners are only now available in consequence of the long-continued drought. The length of time a bed may be considered productive is variable, depending upon the constitution of the variety and the condition of the situation; but fresh plantations should be made every year for succession. British Queen, Duke of Edinburgh, Elton, James Veitch, Keens' Seedling, Loxford Hall, Oxonian, President, Sir Charles Napier, and Sir Joseph Paxton may be counted as the most popular and best varieties. They can be grown anywhere, always command a ready sale, and the demand is practically unlimited. I believe the proprietors of the preserve factories—sugar boilers as they are called in the Liverpool district—have this year received constant and considerable consignments from Kent and the southern counties. The cost of carriage added to the price of the fruit leads one to believe that there is a most eligible opportunity for the still further development of Strawberry farming in North Wales and the Border counties.

The succulent character of the Strawberry is such as to make it a necessity that it should receive most careful handling, and careless picking and packing may be the cause often of unsatisfactory returns. I may mention a fact which came under my notice this last season. In one of the Cheshire markets a careful grower, who invariably takes pains to have his fruits properly presented, was making 6d. and 7d. per quart for as much fruit as he could market, whilst his neighbours were glad to get 3d. and 4d., and oftentimes had to take large quantities to the Lancashire markets, simply because the fruit had been reduced to a pulp oozing through the baskets and was unsaleable except for boiling down. The packing which commends itself most is a system of which I have an example before me. The fruit is laid in clean chipwood punnets holding each a quart, leaves are placed carefully to protect and decorate, the punnets are then placed in a tray divided into compartments and boxed in tiers, so that the berries are not injured in the least, and are lifted from the case just as fresh and beautiful as when they were put in.

(To be continued.)

EXHIBITING CHRYSANTHEMUMS.

I NOTICE several Chrysanthemum societies are offering prizes as follows:—For twenty-four cut blooms incurred, not less than eighteen varieties or more than two of one sort. What I want to know is, would twenty-four distinct varieties stand before eighteen, provided all were good? I suppose you could put up a much heavier stand by staging duplicates of the Queens and Empresses which would throw out some of the smaller varieties, although they might be as well grown of the sort. Supposing A showed eighteen varieties all good, and B showed twenty-four varieties, eighteen of which were equally as good as A's and the other six were as good as the varieties could be, which ought to be first? An opinion expressed on this point in the *Journal* would perhaps assist some young exhibitors besides myself.

I am looking out very anxiously for Mr. Molyneux to fulfil the promise he made some time ago, which was to this effect: "There are many other details in Chrysanthemum culture that cannot be fully dealt with in a short article like this, but I hope at some future time to give exhaustive details of the mode practised in producing exhibition blooms."—CHRYSANTHEMUM.

[Provided eighteen varieties are staged the conditions are complied with. If a person could stage twenty-four varieties in the class he could, in all probability, select from them twenty-four better blooms in eighteen or twenty varieties, and we suspect he would act prudently in doing so. We are willing, however, to publish the opinions of growers and judges on this matter.]

AN OCTOGENARIAN HORTICULTURIST.

ON Monday, the 7th inst., the employés of Messrs. Wm. Barron and Son, of the Elvaston Nurseries, Borrowash, near Derby, to the number of sixty-five, were entertained at dinner by Mr. Wm. Barron, the senior partner of the firm, to celebrate his eightieth birthday. The employés took advantage of the occasion to show the high esteem in which they hold their host by presenting the octogenarian with an armchair, accompanied by an appropriate address. During the evening Mr. Barron gave his guests a very interesting sketch of his past career.

Mr. Barron has been a most enthusiastic horticulturist all his life, having commenced his career of gardening as an apprentice at Blackadder, the seat of Thos. Boswell, Esq., where he made rapid progress in his profession. Having finished his term of apprenticeship, he was appointed foreman in the houses under Mr. McNab at the Botanic Gardens, Edinburgh; from thence he went to Sion House. Having remained at Sion House for some considerable time he was selected to lay out the gardens at Elvaston Castle, the grounds of which are famed for the artistic manner in which they have been designed. Ultimately, Mr. Barron was per-

manently appointed head gardener and steward, in which position he remained for more than thirty years, during which time he enjoyed the entire confidence and respect of his noble employer, and was held in high esteem by all those with whom he came in contact. During the time he had charge of the Elvaston gardens he brought together one of the best collections of Coniferae in this country, some of which have attained the proportions of large timber trees.

Mr. Barron has made himself famous both as a landscape gardener, and for his successful mode of removing large trees, some of them being of great dimensions, amongst which may be mentioned a few of the largest. The first large trees that he attempted to remove were some Cedars of Lebanon at Elvaston. The largest of these measures at the present time 80 feet in height, 9 feet 9 inches circumference of stem, with a spread of branches 63 feet in diameter. This tree is in the most robust health. He also removed a Cedar of Lebanon from Hornsey to Acton, 60 feet high. This required thirteen horses to convey it to its destination. One of the largest trees removed was a Cedar of Lebanon for Sir John Hartop, Bart. This tree measured 50 feet high, 50 feet diameter of branches, and was moved with a hall 18 feet long by 16 feet in width by 3 feet 7 inches deep, the whole weight being computed at 50 tons.

The greatest feat of tree-lifting was, however, accomplished at Dover, when an old Yew, considered to be over a thousand years old, was moved with the greatest success, and is now to be seen in a thriving condition. Mr. Barron is still in the enjoyment of excellent health, thus showing the beneficial results of temperate habits and constant activity.

VINE GOSSIP.

Much has been said lately about Vine leaves being scorched or curled, and I wish to add a few observations on the subject. The last Saturday in July here was a scorching day, though with the wind being north-easterly the temperature was not excessive, but the sun was extremely bright with a very dry atmosphere. My Gros Colman Vines in a span-house running north and south did well up till about eleven in the morning, then the four end Vines in the south-east corner, together with a Madresfield Court, were very much burnt. I cannot understand how it should be so, as this house is well ventilated by five in the morning; in fact, this is always the first house attended to. Between noon and three o'clock I watched the south end very closely, and all was right until about four, then the Gros Colman on the west side was slightly burnt, and a few exposed bunches of Madresfield Court were burnt. As soon as the sun's rays were off the house I syringed all the injured Vines thoroughly, anxiously watching the result on Sunday, but no farther damage was done. On Monday to be safe I used a slight coat of Elliott's Summer Cloud outside the glass to slightly shade the four end, Vines on the east side, and also the south end. The mystery is that supposing the morning burning was caused by insufficient ventilation, it could not be so at four in the afternoon. The Grapes were at a standstill for at least ten days. In the meanwhile I gave these Vines a little liquid manure, and I am pleased to say the Grapes are swelling well. They will be later, but do not think any worse for the check. The foliage did not fall, but curled very much, though now even these have expanded. Last year the Vines were caught in the same way at the north-east corner, though the Grapes coloured and did as well as the rest, only being later. I expected this time to have seen them somewhat weaker, but it is not so; the crop and berries especially are the best in the house, which I attribute to the extra liberal treatment they received to counteract the burning. The foliage is good up to the height of 4 feet, when the rods turn up the roof, the leaves measuring 12 or 14 inches in diameter, and the laterals fairly strong about 18 inches apart on each side. The burning must be peculiar to the variety, as in the same house I have a fine Vine of Gros Guillaume in the north-east corner with foliage always good. It was not due to forcing, as these Vines were gently started on March 1st, and have only this last fortnight begun colouring. I have at least a dozen good rods of Gros Colman grafted on Muscat of Alexandria last year, which have a bunch or two of Grapes, and these are all that can be desired in colour. I measured a rod of a graft two years old, and find it over 3 inches in circumference with leaves 15 inches across the graft, carrying three bunches, and the stock Muscat of Alexandria four bunches, as it was grafted 4 feet up the stem. I have grown the Muscats on the cool system. Another year I shall try Gros Colman or Black Hamburg, as I am sure grafting Gros Colman is a step in the right direction. I remember a house of Lady Downe's at Garston in Meredith's time, which faced the north, and the Vines doing capitally, and I believe this would be the right treatment for Gros Colman if started early. Having the management of these houses in my own hands I have no one to blame, so I am enabled to speak with authority when I say it is not the fault of ventilation. I ought, however, to say that the wind being strong from the north-east we had to be careful in opening on that side. On the Friday, Saturday, and Sunday named the air was full of black midges like thrips; Dahlias, &c., outside were smothered with red spider. This must be a good year for red spider, for the supply of water being generally short with other favourable circumstances, gave the enemy a good chance. I see now my Gros Colmans are inclined to have a few on the leaves, and as the Grapes are colouring I cannot syringe.

We have a lean-to house facing east planted with Muscats. The wires are only 12 inches from the glass, and the foliage is a little affected, but the fruit is swelling freely. In this case I believe also they were perhaps rather dry at the roots, the border being shallow. I am more than ever of the opinion that the farther the foliage is from the glass the

better. I have another lean-to Muscat house facing south, the wires 15 inches from the glass, and the Vines are in perfect condition; position may have something to do with this, but the distance of the wires from the glass is also important. I inarched Madresfield Court on Gros Colman last summer and have one bunch of Grapes. I did this to see if it would crack. This bunch is finished and in good condition. I shall graft Gros Colman on Gros Guillaume next year. This should do well.—STEPHEN CASTLE, *West Lynn*.

EPILOBIUM OBCORDATUM.

As a rule Epilobiums are far from being popular, though for what reason I do not know, the majority being really desirable plants, and that

Fig. 40.—*Epilobium obcordatum*.

should be in all mixed borders. *E. angustifolium* and its var. *alba* cannot be surpassed for marshy ground. When planted in bold masses they have the advantage of being able to take care of themselves better than most plants in a similar situation, and during the flowering season are very attractive. This species has also been very effectively used on the margins of lakes and streams. *E. hirsutum*, though not so showy, may be advantageously used in the same way; it is, however, a coarser grower, and should be placed in the background. Then there are *E. montanum*, *E. roseum*, and *E. palustre*, all excellent border plants. The chief thing to be guarded against with Epilobiums is their seeding in the border, but this is easily remedied by cutting the tops before the seeds ripen.

The dwarf-growing sorts are essentially rockwork plants, and especially *E. obcordatum*, shown in fig. 40. It is a native of the Rocky Mountains, where it is found at over 1000 feet above sea level. It is perfectly hardy in our gardens, standing any amount of drought, and the present season has been the best for this plant we have seen since its introduction, flowering as it has done incessantly from June until September. Dry sunny slopes are the places to be chosen on which to plant it, and as it has a trailing or procumbent habit it soon covers the place allotted to it. The flowers vary from three to five on each stem, over an inch in diameter, and of a lovely dark rose colour. It is easily injured by damp during the winter season, and should be protected by a "cloche" or

piece of glass raised above the plant, so as to allow free access of air. A difficulty is often experienced in propagating it, but in heat it strikes readily at this season, when the cuttings have been thoroughly ripened. Others suitable for rockery, and which are also very desirable, are *E. rosmarinifolium*, *E. sericeum*, *E. Fleischeri*, *E. alpinum*, and *E. glabellum*, the latter being a fine plant for edging, having pretty marbled foliage.—M. S.

[The woodcut represents a strong plant, but the shoots are usually more procumbent than is shown in the figure.]

BEDELL'S TELEGRAPH CUCUMBER.

In the "Notes on Vegetables," page 205, your correspondent speaks very highly of Cardiff Castle Cucumber, and as I have two hotels to supply with this vegetable, also a private establishment, I wish to say a few words in praise of Bedell's Telegraph. This and the old Telegraph I have grown side by side for three years, so I think I have given it a fair trial both in houses and frames, and when a garden is worked on the market system the greatest care is needed in getting those varieties which will pay for the trouble and give employers satisfaction. This Cucumber only needs a fair trial to become a general favourite.—W.

[Accompanying this note were two fine even fruits of the variety named, which appeared to well justify our correspondent's commendation. They are much like the Telegraph, except, perhaps, the fruits are rather stouter with more bloom than is usually seen on this variety. Nearly every market gardener has a selection of his own that he has proved reliable, but some of the largest growers are now depending almost exclusively upon Cardiff Castle.]

THE LATE DROUGHT.

THE weather during the past few months has proved a great drawback to gardeners where a plentiful supply of water was not at command. Although the hoe and rake have had an easy time, the plumbers will most likely find plenty of work next winter in repairing watercans, water-barrows, &c. During the present season, in many cases crops have suffered severely through an insufficient supply of water, which perhaps, if obtainable, had to be carted a long distance, so that it would be impossible to give all crops requiring it a sufficient supply. Every lady and gentleman possessing a garden, and especially those who are making, or are intending to make, new gardens, would do well to consider the present season in this respect. Money spent in the construction of tanks, laying in pipes, and having taps at intervals throughout the garden, would be well invested. In all cases it would not be possible to do as I have suggested, but in laying out new gardens this should rank among the first considerations in its construction. In the case of a short supply of water much could be done in retaining the moisture in the soil by giving a mulching of lawn mowings or manure (the latter cannot always be spared for that purpose), to such crops as Peas, Scarlet Runners, French Beans, Cauliflowers, &c., and then to give a thorough soaking of water; they will not suffer for some time. Some object to lawn mowings for mulching, as they say the seed of the grass is brought into the garden and cause a trouble afterwards, but where a lawn is kept in proper condition there will be no fear in this respect, but I would recommend litter from the stables, if it could be obtained, as a mulching.

Now I come to another most important point to be observed as regards the water supply, and that is the rainfall. In places that I have visited, and others in which I have acted as gardener, I have noticed that provision has not been made to economise the water that falls on the roofs of the houses. I have frequently seen water running into drains from the glass structures that would possibly have given a supply of soft water through a season like the present, and, moreover, prove more beneficial to plants and vegetables watered with it. I have pointed out this to gentlemen under whom I have served, and have asked to have good tanks built for the reception of soft water, but the expenses of the same appear to be the great drawback; at the same time, if this is studied, the proprietor would be the gainer in the long run. If tanks were built and cased with cement, and a pump attached to each, sufficient water would be obtained through the winter months to meet the supply required for a long time.

Where tanks are constructed in the garden it is advisable that these should be filled every evening (and this would not be a difficult task where a tap is attached), as the action of the air would greatly soften the water and bring it to nearly the same temperature as that of the ground.—ROBT. D. LONG.

LILIUM CANDIDUM.

ANY bulbs of this useful Lily required for potting should be seen to at once, as there is no better time for doing this than immediately after the flower stems show signs of decay. The roots have, however, had so little to encourage them that they are much later than usual in starting into growth, which is only now commencing. It is now well recognised by many that this is the best time for potting. Three bulbs according to their size may be placed in 6 or 7-inch pots, using a compost of fairly rich loam. These pots will be sufficiently large the first season, after which the plants may be shifted into larger pots as they may seem to require. If potted at once the majority of the young roots may be secured, and as these fill the pots they may be introduced into the greenhouse, and from

this to a warmer structure if early blooms are required. It is not easy to over-estimate the value of this, one of the most useful of all Lilies, and which is one of the oldest inhabitants of the herbaceous border.—J.

INSECTS AND CANKER ON FRUIT TREES.

Your correspondent Mr. Hiam must indeed be satisfied with the experiments he has made to decide so clearly, in his own opinion, that insects, and insects alone, are the cause of canker in fruit trees. I have had for some years to battle with canker on gravelly subsoil, and having succeeded in bringing the trees, both Apples and Pears, into sound and healthy condition, I must express a slightly different opinion from Mr. Hiam, as both treatments appear to have resulted the same.

I am of opinion that, like many other instances of insect attack on plants and trees, they suffer chiefly in consequence of debility through deficient root-action. Our trees, now shining with health and burdened with fruit, have had no attention paid to the wood, with the exception of very careful pruning. What has been done is to carefully transplant each, having them removed from the home kitchen garden outside the walls, although well sheltered. Holes were made about 5 feet in diameter and 10 to 12 inches deep, and in planting great pains was taken to preserve uninjured every root, pruning the ends with a very sharp knife, and every rather strong root was notched at some 6 inches or so. Too much importance cannot be attached to using a very well sharpened knife, for the ends of these roots produce an abundance of new and healthy roots the first season. It is my rule to have two or three good knives at hand and kept sharpened in turn as needed by most reliable hands, as only such are to be trusted with the work. Soil is the next important matter. A couple of barrowloads of turfy sods are placed grass side downwards quite level, next a barrowful of well-decayed manure, then one of loose compost. The tree is then firmly seated, and this latter point of firmness is of the utmost importance, stretching out every root which is sound. In planting we use old Cucumber or Melon beds, and the roots speedily take hold of this; then fill in with the best of that thrown out, fresh soil, bones, manure, lime rubbish, or what may be at disposal, not treading too firmly. We then put on a good covering of half-decayed manure, or, better still, spent hark, and stake securely from three points. Nothing further is needed, except an annual dressing with manure or other good compost over the roots. Marl is very good in helping to make a firm surface, which is never disturbed. Planting is done in October.

I may here give a hint upon an old practice of great value to fruit trees, or almost any trees—namely, that of giving liquid manure during winter. Nothing, we find, assists more than this, and we are preparing to extend the practice. Perhaps our good friend Mr. "Thinker" is busy with some scheme of this kind, but I am sorry to notice we have had none of his humorous and instructive paragraphs of late.—LATHYRUS.

HYDRANGEAS.

It would be difficult to name any hardy flowering shrubs more suitable for growing in pots for the many forms of decoration for which flowering plants are required than these plants. They are comparatively easy to grow, and amateurs with a frame or a few handlights and a greenhouse may grow them to the same excellence as the professional gardener with more glass structures and greater accommodation. The latter, by a judicious system of treatment and forcing, can produce them in succession over a period of several months, but with the former this can only be accomplished in a very small degree, and the amateur can succeed in bringing two or three batches into flower at different times so as to form a succession.

In order to grow these plants well in small pots it is necessary to have a few good plants of two or three varieties placed out in fertile garden soil in an open sunny position. This is the best system for the amateur, while those who want to force the plants into flower early in the season should keep a few stock plants in pots. Those should have the protection of a cold frame until the weather is sufficiently genial to turn them outside without injury to the foliage made; in fact, prior to turning them out they must be carefully hardened so that they are not checked in their growth. Those grown in pots will yield cuttings in suitable condition for striking before those are sufficiently ripe on plants growing outside, which can be rooted a few weeks later, and thus form capital successions to those taken from plants in pots.

Cuttings from plants that have been grown in pots should be taken without farther delay, for growth has ceased and flower buds are formed. If left too long the shoots become woody and too hard to strike freely, in fact they are a long time striking in that condition, and many may fail to form roots; but when taken as soon as growth ceases and the formation of the flower buds has commenced, the wood is moderately soft and will root quickly and freely. The cuttings should be 2 or 3 inches in length, and cut clean below a pair of leaves with a sharp knife. The two lower leaves need not be removed, but inserted with the cutting into the soil. The cuttings strike root equally as well without the leaves as when retained, but they assist in the development of the flower bud already formed. They should be inserted into 2-inch pots in a compost of good loam and a little sand; a little of the latter should be used for the base of the cuttings to rest upon. After insertion a good watering should be given, and the cuttings placed under handlights where a temperature of 60° to 70° is maintained. The handlights should be made air-tight and kept perfectly close and shaded from the sun until the cuttings are rooted.

It is possible to root the cuttings by this method without exciting them into fresh growth. I have tried various ways of rooting them without pushing them into growth, and the system devised has answered as well as any. If the plants are left in heat after they are rooted they frequently start into growth, but this must be avoided by gradually hardening them to the conditions of a cold frame. If this is carefully done, and the young plants are given cool treatment as early as possible after they are rooted, they will not fail to perfect and ripen their buds and stems.

The amateur who only possesses handlights and cold frames in addition to his small greenhouse may also root the cuttings very well, which will this season be ready for insertion from outside plants.

The warm dry weather which has prevailed has brought the growth forward very quickly, but it has been found necessary on several occasions to thoroughly water the plants intended to supply cuttings. The cuttings from these will root freely enough under a handlight in the greenhouse if kept perfectly close and treated the same as advised for those placed in a heated structure. They will also root in a cold frame that can be kept close, but better in a handlight where air can be excluded from them.

The young plants when rooted should be grown in a cool place until the approach of frost, when they can be placed in a frame where frost can be excluded. Our earliest plants usually occupy a position in ainery at rest until the commencement of the year, the later plants being kept in cold frames, and protected with mats if occasion requires. These plants are hardy enough and will bear frost, but it does them no good, and therefore should be avoided, for it frequently ends in the destruction of their foliage, which we endeavour to preserve.

Another, and a very reliable system of preparation for early forcing, is accomplished by striking a good number of cuttings in spring. The cuttings are perfectly soft, and thinned out from the plants in cold frames after they have made sufficient growth for the purpose, that are intended to supply cuttings in late summer. These are rooted in brisk heat, either in the propagating frame or under handlights in the Cucumber and Melon houses. Each cutting is inserted singly in a small pot, and directly they are rooted they are gradually hardened and placed in cold frames, giving them abundance of air until the weather is sufficiently genial for turning them outside. When the small pots are well crammed with roots, which is generally the case by the time the plants are placed outside, they are transferred into others 4 inches in diameter. The soil, which consists of good fibry loam, sand, and one-seventh of decayed manure, is pressed as firmly as possible into the pots to insure a dwarf sturdy growth.

After potting, the plants are arranged in an open sunny position. Sometimes they are plunged to save labour in watering, but when this is done care is taken not to allow them to root outside their pots. The plants remain in this position until autumn, when they are placed under cover and treated the same as those rooted at this season of the year. These are only potted once during the season, and the result is plants with large foliage and stout thick stems not more than 6 inches high by the time they are housed. Plants prepared by this method are certain to produce early in the season enormous heads of their beautiful flowers.

Their after treatment will be referred to in another article.—B.

THE GRAND DUKE PLUM.

At the Royal Horticultural Society on the 8th instant, a seedling Plum was exhibited by Mr. Laxton, and with it for "comparison," as stated on the card, some specimens of a small Plum labelled "Grand Duke." If this was the correct name, the specimens were mis-shapen, undersized, and prematurely ripened if from out of doors. As I am responsible for the introduction of the "Grand Duke," which was raised here some years since from the Autumn Compôte, and I have stated that it ripens in October and is very large, those who saw and believed the Plum exhibited on this occasion to be true would have just cause to feel aggrieved if they had purchased the sort on my representation. Amongst the number who visited the Show there were many whose good opinion I value extremely, and I should be sorry indeed if the fruit exhibited would cause them to think that I had attached an untrue description to the Grand Duke. For your satisfaction I send you some fruit of the Plum as it is grown here, which I hope will reach you in good condition, that you may be able to judge of its character.

If the precedent set on this occasion by Mr. Laxton be allowed, horticultural exhibitions would present a lively scene, as contending exhibitors would not choose the best productions of their rivals as "foils" or "comparisons" to their own exhibits.—T. FRANCIS RIVERS, *Swobridge-moor, Herts.*

[We have received specimens of Grand Duke from Mr. Rivers, some from trees in the open ground, which are of course quite unripe, as the sort is not in season till October, and others from trees in an orchard house. The latter are large handsome Plums, and of excellent quality.]

ROYAL CALEDONIAN SOCIETY'S SHOW.

THE autumn Show of the above Society was held in the Waverley Market, Edinburgh, on the 9th and 10th inst., under the most auspicious circumstances. The weather was good, the number of exhibitors was large, and the attendance of the public most satisfactory. There were about 1500 entries, vegetables being perhaps most largely represented, and plants the worst. Fruit was a large show, of Grapes alone about 400 bunches being set up. Apples were also staged in very large numbers, but flowers were hardly up to the average. For the first time bees and their products formed an attractive and appropriate addition to the Exhibition.

FRUIT.—For the collection of twelve sorts, the prizes being £6, £4, and

£2, three exhibitors staged, and of these Mr. Murray, gardener to the Marquis of Ailsa, Culzean Castle, Ayrshire, was successful in obtaining the first place with a Cayenne and Prince Albert Pine Apple, Black Hamburg and splendid Muscat of Alexandria Grapes, good Noblesse and Stirling Castle Peaches, Elruge and Pitmaston Orange Nectarines, Brown Turkey Figs, a brace of Melons, fine Worcester Pearmain Apples, and Kirke's Plums. Mr. Morrison, gardener to Miss Nisbet Hamilton, Archerfield, Drem, second with good Pine Apples, four kinds of Grapes, Muscat of Alexandria, good Gros Colman, Gros Guillaume, and Trebbiano, fine Castle Kennedy Figs, &c. Mr. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisborough, third. The Grapes in this collection were the weak point, other fruit being generally fine. Three collections were set up for the prizes offered for a collection of eight sorts of fruit. Mr. McIndoe was first here with good Gros Colman and fair Black Hamburg Grapes, a Melon, Princess of Wales Peach, Durondeau Pears, &c. Mr. McKelvie, gardener to the Dowager Duchess of Roxburgh, Broxmouth Park, second, good Muscat of Alexandria and Noblesse Peaches being the most notable examples in this collection.

Prizes of £6, £4, and £2 were offered by the Corporation of Edinburgh for twelve bunches of Grapes, six to be black and six white. Mr. Hammond, gardener to Sir Wilfrid Lawson, Bart., Brayton, Carlisle; Mr. McKelvie, Mr. Murray, and McIndoe entered the list for three prizes, the first three being successful and taking the prizes in the order named. Mr. Hammond's bunches were not large, but very well finished. The sorts were three bunches each of Gros Maroc, very fine; grand Alicante, finely finished Raisin de Calabre, and Muscat of Alexandria, which would have been extra fine a month previous, but as staged a little too old. Mr. McKelvie's were less equal, some of the bunches being much smaller than others. Alnwick Seedling was grand, so also Muscat of Alexandria, Alicante fine, Raisin de Calabro good, and fine Gros Colman, Gros Guillaume, and Buckland Sweet-water. Mr. Murray's fruits ran these rather close, his Golden Queen being wonderfully fine, as also Alnwick Seedling; Mrs. Pince fine, though showing its general lack of colour, very good Muscat of Alexandria, and Foster's Seedling. Mr. Hammond was again first with eight bunches of Grapes with good Golden Queen, Gros Maroc, Alicante, and Raisin de Calabre. Mr. Jenkins, gardener to Brodie Cochrane, Esq., Aldin Grange, Durham, second. Alnwick Seedling and Alicante were fine in this lot. Mr. McKinnon, gardener to the Viscount Melville, Melville Castle, Lasswade, third. For four bunches there were twelve entries. Mr. Boyd, gardener to Mr. Forbes, Callander Park, Falkirk, leading with very good Lady Downe's, fine Muscat Hamburg, Black Alicante, and Black Hamburg. Mr. Hammond second, Golden Queen, Gros Maroc, and Alicante being fine. Mr. McKelvie third. Mr. Kirk, gardener to Mr. Palin, Norwood Park, Alloa, staged examples of the following, the berries being of extraordinary size:—Gros Colman, Duke of Buccleuch, Cooper's Black, and Madresfield Court. Mr. Boyd was first for two finely finished medium-sized bunches of Black Hamburg. Mr. Smith, Speddock, Dumfries, second, and Mr. Day, Gartleston, for two bunches Muscat of Alexandria was first with really fine examples. Mr. McKelvie staged two fine clusters for the second place. For one bunch of the above Mr. J. King, Middleton House, was first, and Mr. Boyd second. Mr. Murray, Polmont, was first for one Black Hamburg, Mr. McKinnon being second. Messrs. Hammond and Boyd took prizes for the Alicante, both with grand examples. Mr. J. Cocker, gardener to Mr. Ure, Bonnybridge, had the best example of Alnwick Seedling, Mr. Boyd being second. Mr. W. Murray, Polmont, had first place for Gros Colman and Lady Downe's, Mr. McIndoe being second with the former and Mr. Boyd with the latter, the Lady Downe's being specially fine. Mr. Boyd, with Waltham Cross, took the prize for any white Grape other than those named. Duchess of Buccleuch was the finest flavoured white; Mr. Machattie, gardener to the Marquis of Lothian, Newbattle, being first, and Mr. McIndoe second. Mr. J. King had the finest bloomed bunch, and for two pot Vines Mr. J. Lamont was first.

Pine Apples were not numerous, but good. Mr. Morris had honours for two, staging good Smooth Cayenne; Mr. McIntyre, gardener to Sir C. Tennant, Bart., M.P., The Glen, Innerleithen, second; Mr. Boyd had the best Queen, and Mr. McIndoe the best Smooth Cayenne. Mr. Henderson, Parkhill, Polmont, had first, and Mr. Niel Black, Darlington, second, for a bunch of fine Bananas. To Mr. Hammond the award went for the best green-flesh Melon, Mr. McKelvie having the best scarlet-flesh variety. Mr. Hammond with good Barrington took first for twelve Peaches, Mr. Low Viewforth House, Stirling, being second. Mr. Brown with Pitmaston Orange Nectarine was first, and Mr. D. Murray second.

For a collection of six sorts Pears, Mr. Hunter, gardener to Earl of Durham, Lambton Castle, Durham, was first with grand examples of Bellissime d'Hiver, Bon Chrétien, Beurré de l'Assomption, Beurré d'Amanlis, Souvenir du Congrès. The same exhibitor also took first for six Pears with Gregoire Bourdillon. Apples were quite a show in themselves, all the classes being well filled and keenly contested, the orchard house fruit from Hutton Hall and Lambton, however, handicapping rather heavily those who could only stage out-of-door fruit. Mr. Hunter had first for twelve sorts, staging fine examples of Flower of Kent, Ribston Pippin, Lord Suffield, Worcester Pearmain, Ecklinville, Peasgood's Nonesuch, Cox's Pomona, and Cellini. Mr. McIndoe second, and also first for six sorts kitchen. Gascoigne Seedling, Washington, and Dutch Codlin were very finely shown. Mr. Brotherton, gardener to Earl of Haddington, Tynninghame, was second, Warner's King, Kentish Fillbasket, and Mère de Ménage being the best. Mr. Hunter had first for two sorts dessert Apples with Jefferson and Worcester Pearmain, Mr. Murray second with the latter and Early Julien. Of single dishes the finest were Ecklinville Seedling, from Mr. Duncan, Haddington; Lord Suffield, from Mr. Blackie, Leith; Peasgood's Nonesuch and Lord Derby from Mr. McIndoe; Warner's King from Mr. Brotherton. An exhibitor who staged Old English Codlin received the first prize for Keswick Codlin.

For a collection of ten sorts of hardy fruits Mr. Fairgrieve, gardener to the Dowager Duchess of Athol, Dunkeld, was easily first, Shipley Apicots being really grand. Peaches and Nectarines were also fine, as also Plums. Mr. McIndoe second, and Mr. Dow, gardener to Sir D. Baird, Bart., Newbyth, third.

Among the plant classes the best prizes were offered for a table arranged for effect. Messrs. Ireland & Thomson were easily first among nurserymen,

their arrangement being a thick groundwork of various Ferns, among which a few graceful Palms, Crotons, Pitcher Plants, and Tuberous Begonias were dotted, the edging being a drooping line of *Ficus repens*, with a few *Isolepis gracilis* and variegated *Panicum*, backed with a line of Maidenhair and graceful Crotons. Messrs. R. B. Laird & Sons were second. In the gardeners' class, Mr. Grossart, gardener to Mr. Buchanan, Oswald Road, was easily first, though we have seen much better tables set up at former shows by the same gentleman. Mr. R. Cockburn was second. Pot plants were generally inferior, though, as a rule, the winning collections were good. Mr. Patterson, Millbank, had the best six stove and greenhouse flowering plants, staging *Ixoras* *Pilgrimi* and *Williamsi*, *Ericas* *Marnockiana*, *Iryana*, and *Turnbulli*, and *Statice profnsa*. With a good Heath Mr. Patterson also took first for the best single greenhouse plant, also first for three Cape Heaths. Mr. Scott, gardener to Lord Elphinstone, Carberry Towers, was first with a *Dasyllion*, *Phormium*, *Asparagus plumosus*, and *Yucca aloifolia*; Mr. Grossart being a close second. Of Orchids, Mr. Grossart was the only exhibitor of four and one, the best plant being a fine *Laelia elegans*. Ferns were numerous shown, *Adiantum* themselves being a good show, and although the specimens were not large they were very fresh. Of the latter, Mr. Grossart staged a fine example of *A. Flemingi* in his winning four. Mr. Kerr, Sunlows, Kelso, and Mr. J. Canning had respectively first and second prizes for three Tuberous Begonias, each with well-grown little plants. Some good Geraniums were set up, Mr. D. Plenderleith having the best.

Of cut flowers, those which attracted most attention were the Roses, Messrs. Cocker & Son, Aberdeen, taking first prizes for thirty-six and eighteen blooms with very fine fresh buds; Mr. H. Dickson, Belfast, being second for thirty-six, and Mr. Smith, Stranraer, for eighteen. Messrs. Ireland & Thomson and R. B. Laird & Sons set up fine collections of stove and greenhouse plants, the prizes going in the order of the names. Mr. Campbell, The Cove Gardens, Gourrock, was the only exhibitor who staged presentable *Gladioli*, and these were not up to this exhibitor's usual style. Messrs. R. B. Laird & Sons, Messrs. J. Lamont & Son, and Mr. D. Pearson, Beechwood, were the chief winners for the various kinds of Dahlias; Mr. Kerr of Sunlows and Mr. G. Dingwall, Braes House, Perth, showing fine *Hollyhocks*. Mr. A. Gray, Dunkeld, took the chief prize among the amateurs with some beautiful Rose buds; and Mr. G. McClure and Mr. J. Wynter, Linlithgow, had the best bouquets. Messrs. Dickson & Co. showed fine collections of Carnations, Picotees, French and African Marigolds, and Verbenas; Mr. R. Munro, Portobello, herbaceous blooms; Mr. Sutherland, Lenzie, extra fine Pansies, and Carnations and Picotees; Mr. Forbes, Hawick, *Hollyhocks* and other florist flowers; and Mr. T. S. Ware, fine collection of bouquet, single and Cactus Dahlias.

The vegetables were a very large show. Mr. J. Murie, Craigmillar Gardens, and Mr. Logan, Castlelaw, Coldstream, getting the first and second prizes for a collection of twelve sorts grown by market gardeners. The first prize in gardeners' class went to Mr. Wm. Low, gardener to Mr. Paton, Viewforth House, Stirling, who had a grand lot. In this collection were grand white Celery, Cranston's Excelsior Onions, Musselburgh Leeks, Veitch's Autumn Giant Cauliflowers, Stratagem Peas, Mammoth Negro Beans, James' Intermediate Carrot, &c. Mr. Potter, gardener to J. W. Laidley, Esq., Sealcliff, North Berwick, second with a good lot. Of the single dishes, the most prominent for good culture were Leeks from Mr. Broom, Abercainey, and Mr. N. Glass, Carbrook; Celery from Mr. Cairns, gardener to the Earl of Home, The Hirsell, Coldstream; extra fine Onions from Mr. Murray, Culzean; and Tomatoes from Mr. Scott, Carberry Tower, and Mr. McIndoe, the latter, though only second, to all appearance being the better sample. For twelve sorts Potatoes, Mr. O. Bigham, gardener to W. O. Rutherford, Esq., Edgerton, Jedburgh, was first with a clean fine lot, *Cosmopolitan*, *Reading Russet*, and *Ashtop Fluke* being the best. For six sorts, Mr. McPherson, Elgin, was first, *Village Blacksmith* being the most notable sort in this lot. Mr. Deverill, Corn Hill, Banbury, exhibited a collection of twenty-seven sorts of Onions, which contained notable specimens of *Rousham Park Hero*, *Anglo-Spanish*, *Main Crop*, *The Wroxtton*, &c. Some fine Runner Beans, *Ne Plus Ultra*, were also exhibited by the same gentleman.

Among miscellaneous exhibitions a table of curious plants was shown by Mr. Lindsay from the Botanic Gardens; Messrs. Methven & Sons set up a table of decorative plants; Mr. Inglis, Kelso, collections of Dutch bulbs.

It may be added that the financial result was in every way a success, the number of visitors who went through the Show being above the average.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE APRICOT.

THOSE English fruit and forest trees which are the earliest to open their leaf or flower buds, are by no means the gainers in many seasons for having thus taken the lead when Nature is rousing from the gloom and inaction of winter. Such trees are liable to suffer from the ungenial weather of the average English spring; they are sure to be more or less infested by the first feeders of the caterpillar race, whether these may be insects that have awakened after the period of hibernation, or be broods newly hatched from the egg. Hence it is that the Apricot, budding out as it does ere winter has finally departed, attracts and serves to feed hosts of small caterpillars, whose habits enable them oftentimes to work damage and spoil the trees for one season before the gardener is aware they are about; under glass, however, there is less to apprehend from them. The Peach and Nectarine are also infested, but perhaps less so than the Apricot. The red bud caterpillar, common on the Apple, Pear, and Plum, is quite as partial to the Apricot, attacking either the blossoms or the leaf buds, preferring the former it would seem, and some young trees have the greater part of the buds destroyed by this

tiny caterpillar, which cannot be washed or syringed out of its snug retreat. Kollar recommends a patient examination of the Apricots when the buds are swelling, and should it be noticed that the edge of the calyx is slightly sticky, this caterpillar may be suspected, and if present lifted out without injuring the fruit by using the point of a penknife. The perfect insect of this *Spilonota ocellana*, a species which, unfortunately, like others in its tribe, has a somewhat confusing number of Latin names, lays eggs singly towards the end of summer. It is a narrow-winged moth of a grey colour, having a whitish band dotted with grey. As its appellation implies, the caterpillar is fleshy red, a solitary dark line running from the head, which is black, to the tail. When full fed it spins a white cocoon upon some twig.

Allied to this species is another I have observed on the buds of the Apricot, and which has been reported as occurring in several places. The young caterpillars are dark, almost black, when older of a dull white tinted with purple; the head is black, and there are numerous black spots on the body, some scattered irregularly, some arranged in pairs. My specimens failed to appear as moths, hence their identification cannot be a positive one, but this insect is probably the species called the brown cloak (*Spilonota aquana*) from a conspicuous band of brown upon the fore wings; it is known also as an occasional enemy to the flowers of the Rose. Then the stouter, though also small, caterpillar of *Ditula angustiorana*, which is of varying shades of green, feeds sometimes upon the buds of the Peach and the Apricot, concealing itself dexterously, until it becomes almost of full size. And there cannot be a doubt that the winter moth (*Cheimatobia brumata*) will visit the Apricot when this is cultivated near other fruit trees, or if Hawthorn hedges happen to be adjacent. As the females cannot fly, after they have emerged from the chrysalis they crawl up the stems of such trees as they can reach, which instinct tells them will afford suitable food for their progeny, and lay patches of green eggs, from which caterpillars hatch early. At first, while they distribute themselves over the budding branches, they are hardly to be seen, being no thicker than a horsehair and transparent, nor do they eat much, and they may then be readily washed off the branches. When the weather becomes warmer the caterpillars, should they have been unmolested, devour the edges of buds and blossoms, securing themselves by silken threads. A not uncommon British moth, called *Hybernia rupicaprararia*, is said to attack the Apricot in spring; this is, however, as I believe, a very rare occurrence. The purplish-brown yellow-spotted caterpillar of the beautiful moth styled the large thorn (*Ennomos alniaria*), which feeds commonly upon fruit trees in France, the Apricot included, has not been noticed on this side the Channel. That promiscuous feeder, the caterpillar of the vapourer moth (*Orgyia antiqua*), an object familiar to the gardener, with its pink spots and black pencils of hair, visits the Apricot, but as only stragglers are to be seen, and at a time when the tree is in full leaf, it is not a species to be regarded as harmful. And an eccentric caterpillar of that large moth, the eyed hawk (*Smerinthus ocellatus*) in the course of his wanderings may tarry upon a wall covered with Apricots and Peaches in August, but he is likely to fall a victim to some hungry bird disregarding of his elegant markings.

The Apricot weevil (*Otiorynchus tenebricosus*) though popularly named from the fruit tree now under consideration, and to which it is a special pest, does also occur on other trees, chiefly those upon walls, standards being seldom troubled by its visits. Vines in houses have sometimes been badly injured owing to the insects barking the branches. It is the habit of this beetle to hide through the day, either just below the surface or in those cracks and crannies which are found on most walls, hence while the mischief done by it is often noticed the transgressor may escape scotfree. When a wall is properly attended to, and all holes, large or small, effectually filled up, a lurking place for this foe is disposed of, and it can then only descend to the soil at the base. Thousands have been killed by the application of the petroleum solution to their haunts, and strong tobacco water or the decoction of quassia have been stated to kill them. A layer of salt upon the soil will also end the career of any that may be beneath, and the removal of a few inches of earth round fruit trees about October would carry away both the beetles and their eggs. Many gardeners are accustomed to hunt for the Apricot weevil at night, sheets being laid under the trees beforehand, and then by the aid of a bright lantern the boughs are judiciously shaken and the contents of the sheet thrown into boiling water. Not only this species, but a variety of insects will thus be captured; some, however, are sure to escape. It is rather larger than the abundant grooved or black weevil (*O. picipes*), and at its emergence from the chrysalis has downy spots upon the wing cases; these, however, soon lose their down and appear of a uniform glossy black, the legs are light brown, and it is unable to fly,

fortunately. The larva or maggot from which this weevil is developed is an obese, legless, greyish white creature, clothed with short hairs; it feeds at the roots of the trees to which the mature insect resorts, but also occurs elsewhere, as at the roots of Currants and Strawberries, or even amongst succulent vegetables.

That annoying little beetle, the stem borer (*Rhyncites Olliaræ*), so partial to the shoots of young fruit trees, does not exempt the Apricot from its attack. Its steely-blue tint renders it more visible than if it were of a dull colour, and many of these may be picked off the shoots by examining them in the spring. A cut is made in the side of a twig near its tip by the female beetle, and in the piece so detached which drops off an egg is deposited. Thus she proceeds from twig to twig until all her eggs are deposited. The copper weevil (*R. cupreus*) which visits the Apricot at times, though more frequent upon the Plum, pursues a similar plan to its relative, only it makes choice of the immature fruit, biting through the skin so as to raise a tiny flap. Under this an egg is placed and the pulp closes up, but the fruit is spoiled.

Peaches, Apricots, and Nectarines while the fruit is ripening are sure to attract earwigs. These insects have also been seen devouring the blossoms of the Peach in spring. They must be trapped should there be a suspicion that they are numerous (for they hide during the day) by placing amongst the trees the smallest flower pots, into which a little dry moss is put or small tubes hollowed out of the Elder branches, which will secure many of them. And the slender-bodied electric centipede (*Arthronomalis longicornis*) creeps up at night to conceal itself in the fruit, not to be detected until it has been sent to table.—ENTOMOLOGIST.

THE VIOLENT STORM OF WIND AND RAIN last week caused considerable damage to the fruit crops in many districts, but especially in Kent, where also the Hops have suffered severely. In the neighbourhood of London, particularly in the west beyond Chiswick, where there are numerous orchards of Apples and Pears, the fruits have nearly all been blown from the trees, and the ground on Saturday was thickly strewn with more or less injured fruits. In some districts ornamental trees have suffered greatly, and glass houses have not escaped damage in the more exposed positions. The rainfall was very heavy, and some correspondents record as much as 1 inch in the twenty-four hours from Friday noon to the same time on Saturday.

SOME alteration was made in the awards for FOSTER'S SEEDLING GRAPES at the recent Show at South Kensington, after our notes were taken, and the prizes were ultimately adjudged as follows:—Equal first prizes to Mr. G. T. Miles, Wycombe Abbey Gardens, and to Mr. Allan, Gunton Park Gardens; Mr. J. Horsefield, gardener to Lord Heytesbury, Heytesbury, Wilts, was second, and Mr. T. Taylor, gardener to J. McIntosh, Esq., Weybridge, third.

MESSRS. BARR & SON, King Street, Covent Garden, sent us a handsome specimen of *LILIUM AURATUM PLATYPHYLLUM*, with fifteen large flowers and buds near the upper part of the stem. This variety is a very beautiful one, with well-formed flowers, the petals broad and rounded; the leaves also are very broad, and the general habit is extremely vigorous.

"AN Entomologist" observes:—"Your correspondent who writes upon INSECTS AND CANCER AS AFFECTING FRUIT TREES (page 222) assumes, I suppose, that because he succeeded in working out a cure by the means indicated, therefore the mischief arose primarily from insects. To me this fact is not so apparent, though it would not be wise to pronounce either way unless one had carefully examined the branches affected. From his description I infer the insect must be a mite or *Acarus*, possibly a beetle mite of the genus *Damasus*. It is certainly the case that some of the mite tribe are designed by Nature for the destruction and removal of vegetable matter that is losing its vitality, and therefore in a state of incipient decay."

TURNER MEMORIAL PRIZES.—A meeting of the promoters

was held at South Kensington on Tuesday, the 8th inst., Shirley Hibberd, Esq., in the chair, the object being to organise the fund. Subscriptions were announced amounting to upwards of £100, and resolutions were adopted, without dissent, authorising an appeal to the horticultural public, and appointing an executive Committee. The members of the executive are: Dr. Masters, Messrs. H. Veitch, H. Glasscock, George Paul, J. James, H. Cannell, G. T. Miles, with (ex-officio) the Treasurer, H. M. Pollett, Esq., the Secretary, Mr. James Douglas, and the Chairman of the meeting.

"THERE are few hardy perennials," writes a correspondent, "capable of producing such a number of pure white double flowers for an extended period as *LYCHNIS VESPERTINA PLENA*, which though much dwarfer than usual consequently upon the long-continued drought, still produces abundantly its fragrant blossoms. Were it not so difficult to increase I am sure it would find favour among bouquetists generally, its flowers individually being of such a useful size. These are produced from late in June till arrested by autumn frosts, and in average seasons grow about 3 feet high and makes a large bush."

THOUGH much dwarfer than usual, HARDY PERENNIALS have recovered wonderfully since the recent rains, and now the garden is gay with Tritomas, with their compact columnar spikes of flowers, very effective in large clumps in isolated positions, or in company with single white Dahlias they form quite an agreeable change. Then we have Rudbeckias in variety, very telling border flowers, together with the Japan Anemones, *A. japonica*, *japonica alba*, and the very pleasing variety elegans. All are useful and much admired, though the white especially at this season is of the greatest value. We must not omit a useful group of autumn-flowering Lilliums, *L. speciosum* and its numerous forms, which in northern counties are only just beginning to expand. Michaelmas Daisies or perennial Asters are abundant, of varying shades of blue, lilac, and purple, and averaging from 1 foot to 6 feet high. These produce an amazing number of very useful flowers. Dahlias and Gladiolus are numerous, and with other plants in variety assist in making up an effective display for the middle of September.

"W. D." sends the two following notes:—"TWELVE HUNDRED MELON PLANTS have recently been planted at Harefield Grove for an early winter crop, 1000 of the plants being the new 'Harefield Grove Yellow,' having a very beautiful smooth skin of a bright yellow colour, with fruit of an average weight of from 3 lbs. to 4 lbs. This variety has a good constitution, short-jointed habit, and stout robust foliage; is a free setter, and is a great favourite in the market. The flesh is white and firm, of most delicious flavour, possessing a piquant and pleasing aroma, and eatable and highly flavoured to the skin, which is very thin indeed. It is in every respect a first-rate variety, and its excellent cropping qualities, combined with its high flavour, should make this variety popular. We hear that the stock of seed of this new variety will pass into the hands of Mr. B. S. Williams. The other varieties just planted here are High Cross Hybrid, white flesh and pale lemon-coloured skin; average weight, 4 lbs. to 5 lbs.; and Eastnor Castle, a green-fleshed variety.

"A BEAUTIFUL bedding plant is *SPERGULA PILIFERA AUREA* as seen at Harefield Grove, where the heat and drought of 1885 will ever be remembered, for that district was without rain from Whitsuntide until the early part of September, with the exception of one hour's rainfall, and ordinary bedding plants suffered severely. In some pretty carpet beds at Harefield the *Spergula* is growing freely, and is of a bright yellow colour, much brighter than the Golden Pyrethrum, and it must be regarded as a valuable acquisition to our spring and summer decorative plants. Mr. Gough has used it with *Sedum glaucum*, *Antennaria tomentosa*, *Alternanthera amabilis* and *amœna*, *Iresine Lindenii*, and other kindred plants, and regards it with so much favour that he intends using it largely another season."

A CORRESPONDENT writes:—"I find that an erroneous impression prevails as to who has the MANAGEMENT AND SUPERINTENDENCE OF THE PARKS, COMMONS, AND OPEN SPACES under the control of the Metropolitan Board of Works. I would therefore mention that all duties connected with horticulture, forestry, and management, except constables in uniform, upon commons and open spaces, not parks and gardens, devolves entirely upon Mr. Cochrane for Finsbury Park, Victoria Embankment Gardens, and all commons and open spaces north of the Thames; and upon Mr. Coppin for Southwark Park and all such places south of the Thames. The Parks, &c., Committee holds them as superintendents directly responsible, and issues instructions direct through the Clerk of the Board. The

surveyor of open spaces attends on behalf of the superintending architect to works of a structural kind only, and the superintendent of constables attends on behalf of the Clerk of the Board."

— WE learn from "Meehan's Gardeners' Monthly" that at a recent meeting of AMERICAN FLORISTS in Cincinnati there were 400 delegates present, twenty-one being from Philadelphia and sixteen from New York, those two cities sending the largest numbers. The President, Mr. John Thorpe, delivered an address, in which he stated that 24,000,000 cut Roses were sold last year, and of Carnation flowers about 125,000,000. During the last year 200,000 dollars, or nearly £40,000, had been paid for imported bulbs, chiefly Hyacinths and Tulips. It is supposed that there are 700 persons "engaged in selling florists' supplies, and there are 2000 cut-flower sellers. Florists have increased fourfold in ten years; catalogues have increased fivefold. These make trade for those who do not catalogue. There are 2000 first-class gardeners in the United States, and thousands of amateurs without professional help."

— A PACKET of MESSRS. CASSELL'S MONTHLY WORKS is just to hand, and contains the following:—Part 79 of "Familiar Garden Flowers," with coloured plates and interesting descriptions of the common Barberry and the Hepatica; Part 2 of "Familiar Trees" gives a plate and history of the Cherry; Part 17 of "Popular Gardening" contains continuations of chapters on Rose Culture, Glass Structures, Window Gardening, Orchids, Life History of Plants, Bulbous Plants, and Ferns, freely illustrated; Part 20 of the "Encyclopædic Dictionary" continues this thoroughly useful work from Contagious to "Cost," page 512; Parts 17 of the "Book of Health," and 41 of the "Illustrated Book of Canaries and Caged Birds," being also continued in the same satisfactory style which distinguished the earlier numbers.

JUDGING GRAPES.

I HAVE frequently read the articles in this valuable paper from the pen of Mr. Iggulden, but to none do I give my full support, with the exception of the article of September 3rd, "Remarks on Judging Grapes." I most fully endorse what he there states. It appears to me that judges of black Grapes allow colour to take the precedence over all other points, while they have no regard whatever to flavour, size of berry, or difficulty in culture. I am also a successful exhibitor, and have therefore frequently heard remarks from experienced gardeners which lead me to the conclusion I have arrived at and now state. My opinion thus gathered is that all Grapes shown out of season, however good in colour, ought to be disqualified. If Alicante were judged for flavour in August they would at once be placed out of the prize list, but now they are frequently found filling first and second place from their colouring before Grapes that are well grown and well ripened, full of flavour, and appearing at their proper season.

My favourite Grape among the black varieties is Madresfield Court. I hold it to be the best Grape for July, August, and September, and I am sure it is worthy of greater encouragement than it at present enjoys. It is difficult to finish well at the footstalk, but this would be overcome were it patronised more, and did it take what I believe to be its proper place. A short time ago I was exhibiting at a large show in the midlands, and there I found Alnwick Seedling preferred to many other good black Grapes, and my surprise was increased when I saw how judges, competent to form a reliable opinion, would place Alicante and Alnwick Seedling before good, well-finished Madresfield Court, and this, too, in August, when both Alicante and Alnwick Seedling are known to be sour. It seems useless to expend much labour on the production of Madresfield Court in a high state of finish, when Alicante and Alnwick Seedling, both known to be most easily grown for colour, should supersede it on every hand. It appears to me there should be a revision of schedules, the earliest shows having a class for Black Hamburgs, also a class for any other variety in season, when, I believe, Madresfield Court would hold its own. Then a little later on, when Black Hamburg is past perfection, the first class should be for varieties then at their best, and Black Hamburg should take its place among the second class, while Alicante and Alnwick Seedling would come to the front at the later fruit shows, and deservedly receive appreciation. I feel sure that were growers to devote their attention less to the good old well-established Black Hamburg at all seasons, and more to the varieties that follow it, they will not be disappointed in the result. Madresfield Court is a splendid Grape, fine in berry, good in weight, noble in appearance, and exquisite in flavour. Why should it, then, be passed for Grapes less fine in berry, less in weight, less noble in appearance, and lacking in flavour?

I trust others may fully endorse Mr. Iggulden's and my opinion that Alicante and Alnwick Seedling ought not to appear before the judges' inspection till September has nearly past into October, and that other good varieties of Grapes ought to prevent Black Hamburg always standing in the first place during July, August, and September. I emphatically support Mr. Iggulden in his opinion that Foster's Seedling among white Grapes deserves better treatment at the judges' hands. It is certainly possessed of better flavour than either Golden Champion or Buckland Sweet-water, and yet how seldom we see it placed in an honourable position!—A YOUNG EXHIBITOR.

I AM perfectly aware, and stated as much, that it would be an impossibility for the framers of schedules to meet the wishes of all classes of exhibitors, as the funds would not permit it, even if the committees were disposed to take any proffered well-meant advice, as it happens in too many instances gardeners' advice is not solicited or accepted, and not a few of those responsible for the wording of a schedule know next to nothing about it. One secretary of an important show in this county actually prides himself in the fact that he knows no distinction between Onions and Turnips, Peaches and Plums, and in an off-handed, careless fashion, states so when the numerous complaints are brought before him. In this case it usually happens that it is not the wording of the schedule that is to blame, but the fault lays rather in the selection of incompetent judges. One rule is to the effect that "Judges have the discretionary power to cut and taste all fruits, Pine Apples excluded, also to withhold any prize or prizes where specimens are not deserving of an award," and it is further added that "all fruit must be perfectly ripe and well coloured." If the judges enforced this rule we should hear fewer complaints about unripe and inferior, if well-grown, late varieties being placed before equally well-grown examples of superior and quite ripe sorts. The former may have an advantage in point of colour or "finish," and yet be perfectly sour, therefore unripe and ought to be disqualified.

It appears, however, that "S." (page 223) thinks differently, and he would support the judges in their preference for colour rather than ripeness; but if he extends this doctrine to Grapes he cannot consistently object to unripe examples of any other kind of fruit, say of Peaches, Nectarines, Plums, and even Melons, being awarded prizes. All may be beautifully coloured, and yet quite hard and unripe, but because the show is held (to borrow somewhat of "S.") in August and September, or before these particularly fine examples of showy sorts are fit to eat, the grower is to have "no reward for them." It is quite certain he would get no reward for them if he exhibited them, and exhibitors of unripe Grapes ought also to be made to feel that it is a very unwise proceeding to cut them. How often we see the practice of exhibiting green Grapes strongly condemned, yet in many cases these are nearer ripe than such sorts as Alicante, Alnwick Seedling, Gros Colman, Lady Downe's, and Gros Maroc are when shown during August or early in September. Are they fit to send to an employer's table after the show is over? and if not ought they to be sacrificed? That is the point which I wished to convey in my original remarks, and which "S." evidently misses. If his advice is taken, and the preference is generally given to showy sorts, these will be much more extensively grown and cut for early exhibitions, with the inevitable result of disgusting employers, a result, which I, for one, should be glad to see avoided.

I have always been an admirer of the Alicante Grape, and in my time have tasted some really good examples of it, this being principally in December, when it is at its best, and during the same month I have tasted some that were perfect in every respect as far as appearance was concerned, and yet were quite sour, consequently the fact of a fine appearance is no proof of superior quality. I have before admitted that I am of opinion that extra well-grown Alicante may sometimes be placed before Madresfield Court when the latter is not shown in good condition, but when we see really good Madresfield Court placed third with two lots of only fairly good Alicante first and second the time has arrived for fault-finding. This happened at Taunton last August, and the season before Alicante was placed first in preference to Madresfield Court with this rather amusing difference; the grower, who staged Alicante in 1884 had the Madresfield Court in 1885, and was naturally aggrieved at the consistency of the judges. This man will "try his luck" with Alicante again next year, and several others will have the same variety. To make matters worse, Alicante is now becoming the favourite variety for collections of fruit in August, thus displacing the less easily coloured but good old Black Hamburg. The Chrysanthemum and fruits shows are the proper places to stage Alicante and other late sorts, and for these they may safely be cut, and either sent in to the employer's table shortly after or they may be bottled and kept.

Since writing the above I have read the remarks on judging at exhibitions by Mr. W. Williamson, page 220, and am glad to find this evidently very practical and experienced gardener is of the same opinion as myself as to the relative value of late sorts on the summer and early autumn exhibition tables. For instance, he remarks that "Grapes valuable for their late-keeping properties should be discouraged for early autumn shows, because they are seldom ripe though well coloured, and it is injudicious to try to ripen them." Unless I am much mistaken many more readers of the *Journal of Horticulture* will fully endorse this opinion, and if some of them will give expression to their ideas on the subject much good may eventually result.—W. IGGULDEN.

EXHIBITING DAHLIAS.

WHEN I read in the *Journal* of September 11th, 1884, the qualities which constitute a good Dahlia, I considered that anyone who judged at the different shows should take them as a standard, and the defects stated also were so clear that even an inexperienced person could not err therein. I have always considered the greatest faults in a show Dahlia are green and sunken centres, with high shoulder, and old blooms with open centres or the back florets fallen. If this view is right, were the Judges at Kensington correct in awarding prizes for overgrown, open-eyed, exhausted blooms in preference to equally as well grown blooms for quality without those defects, but smaller and younger? A young bloom has the general preference over an old exhausted bloom, even if not so large. The *Standard* newspaper of the 10th inst. has an article upon the Show,

and states that anything formerly which was not a monstrosity in double Dahlias was not worthy of notice, but now single flowers are coming forward and taking their place. Whatever may be the opinion of the writer in the *Standard*, the double Dahlias will, I believe, still hold their position if quality is to be considered in preference to size. Rules should be laid down like you have given in page 242, September, 1884. In size 4 inches, but from 4 to 4½ or 5 inches should not be exceeded, but with a close centre no less than one-fifth of the size of the flower, and an open eye with back fallen petals should be a disqualification. Exhibitors as well as judges would have a standard by which they could judge the merits of these flowers.—THOMAS GARRATT, *Bishops Stortford, Herts.*

HELIANTHUS MULTIFLORUS FLORE PLENO.

This is one of the best plants of the extensive family of Sunflowers. When planted in quantity in large mixed beds, or in shrubbery or herbaceous borders I know no plant that can surpass it in beauty at this season. It was introduced from North America in 1597, and yet it does not seem to be well known nor cultivated so extensively as it deserves. It is a hardy perennial of compact growth and of easy culture. It grows to the height of from 3 to 4 feet, and flowers profusely from the top to within a foot of the ground. The flowers are double, of a rich yellow, and when cut they stand in water for a long time in good condition. The plant is readily propagated by cuttings and division of the root, and will grow in almost any kind of soil, but like its near relative, the Jerusalem Artichoke, it succeeds better under liberal treatment.—A. PETTIGREW, *Cardiff.*

THE ST. JOHN'S NURSERIES, WORCESTER.

WORCESTER is famed for several remarkable manufactories, one of the most important of which is the wonderful Royal Porcelain Works, where so many beautiful examples of the potter's art have been and still are produced to delight the admirers of such choice wares. The preparation of a world-renowned sauce also gives employment to a large number of persons, and there are several other establishments of nearly equal note. Horticulturally, Worcester is also important, for in its immediate neighbourhood—the pretty suburb of St. John's—is one of the most extensive nurseries in the kingdom, the productions of which have rendered the title of the firm—Messrs. Richard Smith & Co.—familiar to thousands of horticulturists in Great Britain and America. The district is a very interesting and beautiful one for some miles around Worcester, and many excellent gardens well worthy of a visit are readily reached from the town—such as Madresfield Court, Hindlip Hall, Impney, Davenham Bank, Eastnor Castle, Witley Court, and others, while a short run by rail conveys the visitor to the celebrated fruit district, the Vale of Evesham. A gardener could indeed spend a very agreeable holiday in the neighbourhood of Worcester, and find much to interest him; and now that the generosity of employers renders "gardening tours" a part of the year's routine, a hint as to a suitable district may prove serviceable.

St. John's is very conveniently reached from the Shrub Hill station, Worcester, for trams now run at frequent intervals to Messrs. Smith's nursery gates—a considerable advantage, for though the distance is only two miles many persons prefer riding to walking in this degenerate age. The visitor recognises his destination by several ranges of glass houses which shut on the main road, but there is nothing to indicate the surprising character of the establishment. There is no outside display, and a stranger might pass without the slightest idea that it contained so marvellous a collection of plants, shrubs, and trees. Immediately on entering we are reminded of one of the specialties of the firm by a grand bed of Clematis Jackmanni some 20 or 30 feet in diameter, and "a mass" of its lovely purple flowers. This mode of growing Clematises has been frequently recommended, but, unfortunately, everyone does not succeed with them, and in some cases failure is due to want of attention to a simple but important matter—namely, providing a suitable soil. These plants like a rich and rather heavy soil, with a good supply of water, and the less they are disturbed after being planted the better. A trellis is raised a foot or two above the soil, and over this the growths are trained, which is an advantage in several ways, the flowers being seen better, and are less liable to be spattered with soil in stormy weather. For prominent positions on lawns these beds are very suitable, and they might be employed in many gardens with excellent results if care be given to the items named. We shall have something more to say about the general stock of Clematises presently, but in making a tour of the nurseries we first inspected the collections of

INDOOR PLANTS.

Numerous convenient span-roof houses are devoted to the miscellaneous stove and greenhouse plants, which are grown in large quantities to meet the extensive annual demand. Lapagerias, for instance, will give an idea what stocks are required: 10,000 plants of *Lapageria rosea* is an astonishing total, yet that number has been in stock at one time, though now being greatly reduced by the heavy demands; while of the beautiful companion to the species, *L. rosea alba*, there is also one of the finest stocks in the country. Of Ferns all the most useful species and varieties are grown by thousands, and the indispensable *Adiantum cuneatum* is represented by at least 20,000 plants in all stages, from sporelings to good-sized specimens. The very compact-growing *Adiantum Pacotti* is also grown in good numbers. Of the charming *A. farleyense* there is a good proportion of strong young plants; *Pterises*, *Lomarias*, *Lygodium*, and other genera being in similar force. *Bouvardias* are now such popular plants that in most nurseries they are largely grown, but at St. John's they constitute

one of the numerous specialties, and accordingly are represented in thousands of the best varieties. Those that are very largely grown are Dazzler, deep rich scarlet; longiflora *Oriflamme*, also bright red; and *jasminoides*, white. *Gardenias*, *Stephanotis*, *Ixoras*, *Calanths*, *Crotons*, *Dracenas*, and *Aralias* occupy several houses, all the plants being robust handsome little specimens, such as cultivators like to see. Hardwooded plants and other greenhouse occupants form an enormous stock, the *Ericas* being particularly fine healthy examples of the most effective varieties, the winter and early spring flowering sorts of the *hyemalis* and *gracilis* types having much space devoted to them. *Camellias*, *Pimeleas*, *Boronias*, *Grevilleas*, *Genetyllis*, and *Azaleas* each receive a considerable share of attention, and the whole collection of these and countless other plants accommodated under glass are in the most satisfactory condition as regards health. In connection with the indoor plant department it may be mentioned that there is a span-roof propagating house 230 feet long, with a bed in the centre extending the whole length, covered with frames, which is employed in maintaining the respective stocks of plants, and the number of cuttings annually struck in this house could scarcely be estimated; it must certainly run into hundreds of thousands of choice and valuable plants that are every season widely distributed before operations are again commenced.

VINES AND FRUIT TREES IN POTS.

Several span-roofed houses from 100 to 200 feet long and 22 feet wide are occupied with Vines in pots, which at the time of our visit were very promising. The canes were stout, but ripening well, and the general appearance of foliage and growth proving that there was a robustness of constitution which would produce good results in the future. Of the 6000 grown every year in pots nearly three-fourths are Black Hamburgh—good evidence of the popularity of that indispensable variety. Next to that comes Muscat of Alexandria, and then there is a considerable falling off in relative numbers; but that fine variety Gros Maroc is rapidly gaining ground, and Madresfield Court is also advancing in favour, for orders increase, and it is evident that growers are beginning to overcome the difficulties that have hitherto somewhat checked the popularity of so handsome a Grape. Foster's Seedling, Buckland Sweetwater, and a few others are well represented; and then there are smaller numbers of many other varieties which find favour with a few, but cannot be termed "Grapes for the million." Peaches, Nectarines, and Apricots, with other trees for orchard houses are also grown in pots in considerable numbers, and generally deserve equal praise to the Vines for their condition.

CLEMATISES.

Scarcely any firm has done so much to popularise these useful and handsome plants as Messrs. R. Smith & Co., and the well-merited result of their efforts to bring them into prominent notice has been the development of an enormous trade which taxes the skill of the propagator to keep pace with. All are familiar with the announcement "70,000 Clematises," but those who have seen the enormous stock annually dispersed from this nursery would be inclined to think the number under-estimated rather than otherwise. Houses, frames, and beds outside are devoted to this formidable army early in the year, and then as the season advances we find them rapidly disappear, until their places are again filled from the propagating house. Numerous varieties are grown, comprising all the finest varieties hitherto obtained, several handsome novelties having originated in the home nursery.

FRUIT TREES.

The nursery comprises 200 acres, and a large portion of this is devoted to hardy fruit trees, which form so considerable a portion of the trade of the firm. Apples, Pears, Peaches, Plums, Cherries are grown in enormous numbers, together with all other fruits ordinarily in demand. As an example, we may remark that 60,000 Apple stocks were just being budded at the time of our visit, while the trees for sale in all stages, standards or trained, are in proportionate numbers, fine sturdy specimens, vigorous without being excessively luxuriant. Strawberries form another specialty, and occupy a large space, while Currants, Raspberries, and Gooseberries fill some acres. Amongst the last mentioned is a variety named Whinham's Industry, which is rapidly coming to the front as an extremely prolific and thoroughly useful sort, and so meritorious is it that we give an illustration (fig. 41), which faithfully portrays its general characters. Nothing very definite is known of its origin beyond the fact that it was raised in Lancashire by a man after whom it is named, and by whose son it was some time afterwards distributed. Messrs. Smith and Co. first brought it prominently in notice, and it is now rapidly becoming a great favourite with market growers both here and in America. It is of quick robust growth, exceedingly prolific and early, qualities which can be fully appreciated by all who have to supply the markets. We are informed that one local grower intends planting 10,000 of this Gooseberry, as he has conclusively proved its value, having gathered this year a local pot (84 lbs.) from every ten, three-year-old plants on his ground. The berries are large and heavy, at first green, but ripening to a deep red. It is, however, especially recommended for early gathering.

TREES, SHRUBS, AND HARDY PLANTS.

To barely enumerate the most notable of the trees and shrubs in this nursery would fill a volume, and in this hurried glance a few general notes must suffice. The Conifers and evergreens form one department, and comprise a host of handsome plants, such as can scarcely be surpassed. Especially noticeable are the superb gold and silver standard Hollies, which in health and clearness of variegation are all that could be desired, such specimens being invaluable either as single plants in

prominent positions or in the shrubbery. The Golden Thuis and Cypresses, with the elegant *C. erecta viridis*, the silver-like *Picea Engelmanni glauca*, together with grand beds of Pinuses, all deserve more attention than we can give them now, and some more detailed notes

nursery in itself, for 200,000 plants occupy much space, even when closely placed. In the hardy plant department similar enormous numbers are repeated, and the collection, both as regards extent and choiceness of the species or varieties, is one of the best in England.

Fig. 41.—WHINHAM'S INDUSTRY GOOSEBERRY.

must be reserved for another issue. The deciduous trees and shrubs occupy several acres of land, Oaks, Planes, Limes, Maples, and ornamental Thorns forming the bulk of the stock, all the best of the flowering shrubs being included. Roses form another department, a

Everything is on a most extensive scale in the St. John's Nursery, as the foregoing notes to some extent will indicate; but one additional fact may be stated that well shows the kind of business carried on—namely, that an average of 200,000 flower pots are required every year,

and the name of this firm must be a welcome one in Weston-super-Mare. So wonderful a business could only have been established on the soundest principles, and it is only by a strict observance of these that it has been advanced to its present position.

PELARGONIUMS IN THE FLOWER GARDEN.

As the time for propagating and increasing these is at hand it may be well to consider if we have any more useful plants in the flower garden and for the summer decoration of flower beds and borders generally, than these. In my opinion we have not, and a few extra hundred cuttings inserted at this season are always acceptable in spring and at bedding-out time, when it may be decided to plant a few more Pelargoniums than usual. Coleuses have been largely used in some gardens. They look fairly well for a short time in August or during the hottest part of the summer, but they are a long time in coming to perfection after planting; indeed, in a cold wet season they never do, and they decay very early in autumn.

These are the reasons we gave up Coleuses in our flower garden. Alternantheras merit the same character. Iresines are a little better, but too brief in duration. The variegated Mesembryanthemum is satisfactory while it lasts, but it goes off too soon in a cold autumn. Other plants might be named which are showy for a time, but they are too short-lived, and do not compensate for the labour and expense devoted to their propagation and culture previous to the time they are turned into the flower beds, and, after many years' experience in both dry and wet localities I have no hesitation in asserting that the most satisfactory class of flower garden plants we possess are the Pelargoniums. Any number of cuttings of them can be secured at this time. They may be rooted in the open air, packed in very closely in either pots or boxes. They do not require much fire heat or expense to keep them in good condition through ordinary winters, and they always turn out healthy in spring. A little extra attention then will convert them into good plants, and they will prove very effective immediately after being bedded out in May. The weather must be bad indeed if they do not make a good show from then until the end of October, and if the blooms are disfigured for a time with rain or rough weather they soon bloom anew when the weather improves. If the flowers are temporarily destroyed the foliage remains good, and this is a great consideration. We frequently manage to keep our Pelargoniums gay until the middle of November, but the majority of the other plants are over long before that time. I wonder if anyone could name a bedding plant which has remained so long in fashion, and is still used largely, than the old Tom Thumb Pelargonium? I grow it in quantity, and although there are many newer ones with showier flowers, I have found none with greener leaves, brighter blooms, and so lasting as this old favourite. Perhaps I ought to explain that I am not placing Pelargoniums against "hardy flowers," but amongst half-hardy summer flower garden plants the Pelargoniums are undoubtedly the most satisfactory.—M. M.

GLADIOLI AT THE CRYSTAL PALACE.

I wish that I could consider the large display of this grand autumn flower at the Crystal Palace as indicative of a revival of its culture in and around the metropolis; but I fear it is not so, for my own stand was the only one shown within 108 miles of London, the nearest exhibitor being Mr. Catley of Bath; and when we consider the natural habitat of the flower, and the fact of its successful culture at Fontainebleau, so much farther to the south, it does seem a remarkable fact that the only exhibitor for competition in the open class came from far-off Scotland, and that two of the exhibitors in the amateurs' class hailed from Yorkshire. It shows what I have always maintained, that the taste for florists' flowers is more fully developed in the north, and that although laudable attempts have been made to galvanise such a taste in the south, they have as yet effected no very great results.

I do not think that the arrangement of the schedule by the Crystal Palace Company was such as to attract growers either amateur or professional. When prizes are offered for collections it is pretty well understood that only large growers can compete. I met there two nurserymen who are very keen in their culture, but who justly said it is not easy unless one has a large collection to cut thirty-six distinct varieties, and that was the lowest number for which a prize was offered to nurserymen, while the sole prize for amateurs was for twelve varieties, and the amount for that no more than was offered for Aster, which could be grown for a few shilling packets of seed, and no more than was offered at a small provincial show. Growers are not attracted by the amount of prize money, but they do look to repay their expenses or partly so. This was utterly out of the question with such paltry prizes as were offered.

There were two large collections of 100 or 120 spikes set up, one by Mr. Campbell of Gourrock in Scotland, who was enterprising enough to bring them and set them up, which he did in very good style. I had been anxious to see them, and as I missed doing so last year, when I heard so much of them, but both he and other friends who had seen them both years said that they were not equal to his last year's exhibit. They were very noticeable for several reasons; one was the great length of the spikes. This had been to some extent, I have no doubt, attained by judicious shading, but with all that spikes with twelve or fourteen expanded blooms on them were not easily obtained, and this was no unusual thing in his collection. Another noticeable feature was the successful manner in which some old flowers, whose days I had thought were past, were shown. Take for example Amalthea, which indeed I never thought

much of; Tour du Monde, Belladonna, Dumont's Dirville. These and many others were shown in this collection in a manner which fully entitled them to be considered first-rate exhibition flowers. In this collection, too, were Horace Vernet, Romulus, a very old but very light flower; Marquis of Lothian, a scarlet seedling; Franklin B. Hankey, raised by my friend Mr. Dobree of Wellington; Sylvie, Anna, Le Perle, Ondine. The one fault that I found with the collection was that it wanted brilliancy; there were too many white and light-coloured flowers. Mr. Kelway's collection consisted almost altogether of his own seedlings, which he has named and distributed, and a few which were put up for certificates. It was a collection of the most vivid and various colouring. The length of the spikes was not equal to those in the Scotch collection, but in brightness of colouring and variety were much superior. There were several new varieties put up for certificates, of which four were awarded—Lord Randolph Churchill, scarlet flushed with violet; Princess Maude, brilliant purple, white throat, and with white lines in the petals; Dora Thorne, yellow, veined with purple, a novel and striking flower; and Lord Ashbourne, light vermillion, of good shape and substance.

Turning now to the amateurs' class, of which there was but one—viz., for a stand of twelve, I fear I must be guilty of a little egotism, for my own stand stood first, and I can, I think, without flattery, say it contained the best Gladioli in the whole Show. I have never put up so good a stand, and never hope to excel them. I suppose the season has been a specially good one for me, for I believe the Gladiolus likes a dry hot summer, but some of my friends said theirs had been very much injured by thrip, of which I had not a vestige. I never once used any shading, and, in fact, they had no more than the most ordinary care. I did not mulch, and am perfectly satisfied now that this is unnecessary, as it was impossible to have larger flowers than mine were. The stand contained the following flowers:—Meyerbeer, with twelve expanded pipes on it; Leandre, a most beautifully soft-coloured flower; Hesperide, a very bright flower, white ground, but very largely flaked with rosy salmon, somewhat loose; Daphnus, a variety of the present year, tall spike of rosy salmon, flamed with slaty violet, and white centre; Delila, a lovely flower, bright rose, flamed carmine, large pure white blotch, the lower blooms measured 5½ inches across; Flamboyant, a splendid spike of brilliant scarlet flowers; Murillo, rosy cerise, white lines, and white throat, a lovely flower, measuring 5 inches across; Seduction, salmon, white blotches, carmine stripes; Tamerlane, a remarkable flower, brownish crimson suffused with slate colour on the edges, creamy yellow marks on the under petals; Feather Gem, a seedling of Mr. Dobree's, rosy salmon, flamed with rose; Archduchess Marie Christine, white, tinted with lilac; and Rabaut, a seedling of my own, to which a first-class certificate was awarded. It had a long spike with twelve expanded flowers of a soft French white, veined at the edges, and very distinct. The second-prize stand contained some very fine flowers, especially Meyerbeer and Ondine. They were spoiled, I think, in the setting up, too much foliage having been added, and there was a lack of quality in some of the blooms.

One cannot cease to regret the difficulty experienced in cultivating this glorious autumn flower, but there is much comfort in recollecting that the price of bulbs is now so much reduced that it does not require a great deal to replenish one's stock, and that some of the finest flowers are no higher in price than Hyacinths, which one only calculates to grow in perfection for one season. It is unquestionably the queen of autumn flowers. Not so gigantic as the Hollyhock, it is yet stately; while the Dahlia, although so symmetrical in form and varied in colouring, can never be compared to it for elegance and variety of tints and shading. Is it utterly hopeless to see more encouragement given to it, and hence, as an inevitable result, more growers cultivating it?—D., Deal.

HENSOL CASTLE,

THE seat of Miss Fothergill in Glamorganshire, is a handsome building beautifully situated in a valley, finely sheltered on the north by a hill, from which a charming view of the surrounding country can be seen to advantage for miles on all sides. The view obtained from this spot stands almost unrivalled for picturesque beauty. To the west of the Castle is a beautiful lake covering 60 acres, which adds greatly to the appearance of the place. It is well stocked with fish, and several fishing boxes have been erected along the banks. There is also a handsome boat-house. Returning from the lake towards the Castle, on the north side I observed some good Coniferae, notably Araucaria imbricata, Wellingtonia gigantea, Cedrus deodara and atlantica, also some of the largest Tulip Trees I have ever seen, and grand old Beeches, Limes, and Oaks. Curiosity led me to measure the spread of an Oak, which was fully 100 feet from tip to tip of the branches, and little more than 30 feet high. This tree was clothed to the ground with branches borne on strong limbs projecting from a proportionate bole. It seemed somewhat singular to see strong branches projecting 20 or 30 feet straight, and then drooping to the ground. This tree in all other respects resembled the common Oak.

There are few features connected with a garden which add more to the beauty and enjoyment than well-kept lawns. Hensol Castle may well be famed for its lawns, which, though extensive, are kept in first-rate condition, and are seen from the principal windows on all sides. The Castle walls are covered with Ivy, neatly trimmed. On leaving the Castle for the kitchen garden, turning to the left we passed along an 8-foot walk with ribbon borders on each side, which were gay (at the time of my visit, August 5th) with a miscellaneous collection of herbaceous and bedding plants. At the back of these borders were some fine Rose beds. Though most of the varieties are old they were blooming profusely, and I was informed they were the "real cut-and-come-again

sorts." The kitchen garden is 2 acres in extent, and surrounded by a wall 10 feet high, well covered principally with Apple and Pear trees trained horizontally. Many of them were carrying heavy crops. The south wall is covered with select Peach, Plum, and Cherry trees, all of which were young, clean, and vigorous. A small brook passes through the garden running from east to west, with a neat rustic bridge in the centre. The ground has a gentle slope towards the brook on each side. The garden is divided into proportionate quarters by 6-foot walks, with Box edgings, and it was well stocked with excellent vegetables, very notably being some fine Asparagus plants in 4 feet beds. Root crops were looking uncommonly well, especially Carrots and Parsnips. A quarter devoted to small fruits was well stocked with fine old Gooseberry, and the Currant bushes were bearing an immense crop. In short, the kitchen garden was in the same high state of keeping as the place throughout. The garden is small, and there are few fruit trees planted in the borders; but immediately to the back of it is a fine old orchard, well stocked with established trees, which were scarcely carrying an average crop. Apple and Pear crops (generally) in this locality are under the average.

Glass structures are rather wanting in this old establishment; but doubtless many of the readers of the Journal have heard or read of the Hensol Old Vine. I think I may safely say it is the largest and the oldest Vine in the principality. The vinery is 80 feet long by 18 feet wide, and the whole ground surface is covered with flagstone, sloping from the walk at the back of the house to the front wall. The Vine (a cutting from the Hampton Court Vine) was planted eighty years since by the late Mr. Crawshaw in a prepared border outside, and introduced through a hole in the wall at the centre of the house. The stem of the old Vine before entering the house is nearly 3 feet in circumference. On entering it branches horizontally off right and left in two leading shoots, which have grown to each end of the house. Rods are trained up the rafters at 4 feet apart to the top, and they fill the house. The border is 80 feet in length and 45 feet broad with a fall to the south. This grand old Vine until a few years ago bore heavy crops of well-finished Grapes, but as there is no artificial heat in the house they did not keep well in damp autumns. More than 900 bunches have been cut from it in a season. The gardener in charge two years ago thought to renovate the old Vine by lifting all the roots and adding a fresh compost. This he did, but I need hardly say at the expense of the Vine, for a season or two at least. Last year it was nearly nude of foliage, and the little it had was weak and sickly. Mr. Dorward, Miss Fothergill's present gardener, informed me that when he took charge of the gardens fully twelve months since he did not know whether it would live or die with no artificial heat at command. The first steps taken were to shade the house with whitening and open the ventilators as little as possible, giving plenty of moisture when the temperature rose high enough to admit of it. The Vine kept the little foliage it had well on in the season, which showed that the roots were laying hold of the new compost. And this season, when the Vine commenced to break, the house was again shaded, and kept close and moist. It must have been a pleasure to the owner, who prizes it very much, to see it break fairly well, and I am glad to say (at the time of my visit) it seemed to be gaining strength and vigour—in fact, it bore a few small bunches. If I mistake not Miss Fothergill will in another season have the pleasure of seeing her old favourite in good condition, under the fostering care of her intelligent gardener, who is deserving of much credit for the clean and orderly manner in which the place is kept.—A. SMITH.

SALPIGLOSSIS SINUATA COCCINEA.

THE singular variety of colour afforded by the different forms of *Salpiglossis sinuata*, a variety hardly equalled by any other genus in cultivation, has enabled this plant to retain its place in popular estimation, notwithstanding the very considerable number of more recent introductions in the class of annual plants. But for one rather serious defect the *Salpiglots* would unquestionably take even higher rank: we allude to their height, which renders them less fitted for small masses or beds than many dwarf but less showy plants. It is true that so-called dwarf varieties have been raised, and are annually offered in the seedsmen's lists, but the difference between these and the older varieties is less marked than could be wished, and much remains to be accomplished in perpetuating a strain of these elegant annuals of decidedly dwarf habit.

Of the numerous distinct shades of colour in which *Salpiglossis sinuata* occurs, none are more pleasing than coccinea. In its general habit and characters it resembles the other varieties; like them attaining a height of 1½ to 2 feet, with erect branching stems clothed with clammy hairs. Its colour is "a clear vivid tender scarlet," relieved by darker veins of the same tint.

Its cultivation is precisely that of the other varieties. The seeds require the aid of a hotbed, and are best sown in March in pots of light sandy loam: they should be thinly distributed, and as soon as the seedlings are an inch or two high abundance of air should be admitted if the weather is sufficiently mild to allow of it, for the *Salpiglots* are by no means tender, and will not bear "coddling." When the young plants are large enough to handle without injury they may be transferred in

small patches to larger pots of light, rich, but well-drained soil. If, however, the seedlings have come up thickly, they will need transplanting separately, or thinning-out. In either case they should, when repotted, be returned to the hotbed, and be kept closed for a few days; after which, about the end of April, they may be placed in a cold frame, and gradually hardened off before planting out in May. A light rich soil, composed of a little leaf mould and thoroughly decayed manure mixed with sandy loam, suits them best. They form a very beautiful bed where the massing system is adopted, but are equally valuable for planting in clumps in the mixed borders, and will flower through the summer.

In favourable localities the *Salpiglossis* may be treated as a hardy annual, the seed being sown in the open border in April, and sturdier

Fig. 42.

plants will be thus obtained, which will, however, bloom somewhat later than those raised under glass.

The *Salpiglots* are all natives of Chili.—W. T.

JUDGING AT EXHIBITIONS.

[A paper read before the Dundee Horticultural Society by Mr. W. Williamson Tarvit House Gardens, Cupar, Fifeshire.]

(Continued from page 221.)

FRUIT.

I WILL now briefly point out the characteristics of other kinds of fruit as bearing on their exhibition qualities. The first to be noticed is the Melon, the point of most importance being flavour with size. If we have a fruit of fine quality we wish plenty of it. Thinness of rind and depth of flesh are to be considered when the fruit is cut; if uncut, the eye, the nose, and a knowledge of the different varieties will have to guide to possibly an unsatisfactory conclusion. I am not an advocate for tasting fruit when judging, especially amongst Grapes, unless to prove their ripeness, or when a variety is unknown, otherwise they should be judged for flavour by their appearance; if the points which indicate good quality are all present it may not be the fault of the cultivator if the flavour is wanting. The next in order are Peaches and Nectarines, both to be judged alike as to size and quality, not to sacrifice the latter for the former, as is too often done, awarding the prize to well-known coarse varieties because they are large, ignoring the claim of finer more inviting fruits. Judges often have great difficulty in deciding when they have two varieties, one coarse but well-grown, the other an excellent variety, but small beside a well-grown fruit of the same sort. The prize should be awarded to the larger fruit, because cultural merit must weigh to a certain extent against quality only. Coloured Peaches should be preferred to light or yellow ones if equal in size and quality. The Fig shows well in dessert, and should be fully ripe, but with a dry skin free from splitting, which comes with over-ripeness, should be solid and sweet. Apricots, Pears, and Plums are much the same value in competition. Some judges would be inclined to give Apricots a point more than Plums, but the one is as easily grown as the other, and as much valued for dessert. Pears may be shown on equal terms with either of the two, some of the late sorts a point better, but the early autumn varieties, of which Jai-

gonelle is the best, should receive the same value. The principal feature which distinguishes these fruits for high quality is the colour produced by the influence of the direct rays of the sun. These fruits never attain the same degree of perfection where too much shaded when ripening. If we look at a Jefferson or Green Gage Plum shaded by leaves, and others from the same tree fully exposed, we are led to suppose they are different varieties, especially when tasted. The rose tint on the amber ground speckled with crimson against the dull yellowish green of the shaded Jefferson indicate the difference between the good and inferior fruits. The Apple, certain varieties of which are highly appreciated for dessert and look well in a collection of fruits. The highly coloured sorts are especially attractive, but lacking in flavour compared with some of the paler varieties. Ribston Pippin is the best of all dessert Apples when properly ripened. Oslin is also much superior to either Irish Peach, Devonshire Quarrenden, Astrachan, or Worcester Pearmain, although they stand unrivalled in appearance. The Apple, when cut, should be firm, with small core, juicy, and aromatic. The judging of small fruits is rather an easy matter. Size and colour are the two principal characters in deciding the prominence each should obtain in the prize list. In regard to Red and White Currants a mistake is sometimes made by exhibitors in cutting the bunches and selecting the parts with the largest berries on them to make them look well as a dish. As these fruits are always pulled with the stalks they should be left intact and judged according to the number and size of the berries on each stalk.

Before leaving the fruit I would like to say something about staging it, which does not receive the attention necessary for the convenience of the public. Let there be a systematic arrangement, a well-defined outline separating the different lots, and cards with bold letters placed over the exhibits in each class with the number and name upon it, so that everyone could see at once the number of competitors in each class, with the respective productions, when the judging is finished. Where practicable, the prize dishes should be placed together to allow of easy comparison.

VEGETABLES.

Vegetables are invariably judged in competition according to their size, that being the chief point of importance, and justly so, if the quality is good also, but any approach to coarseness should reduce their value. Meanwhile size has much to do with quality. If small, they are liable to be tough. To have them in excellent condition they must be tender and succulent, but firm, these qualities resulting from quick growth without check from dryness or want of food. That the good or bad qualities may be discovered they should be cut, the finest to look at being often of inferior quality, and others, again, with nothing in appearance to recommend them, are much superior. Even the same varieties, by different modes of cultivation, are changed in quality yet similar in appearance. Baskets of vegetables are, as a rule, judged without applying the knife. The reason, I presume, is because of the mutilated appearance they would present to the public, but I do not see why the same rule should not be carried out. There are generally sufficient of one variety shown, that a single one from each would not detract in the least from the appearance of the collection. After being cut they could be placed beside the basket for inspection. In judging vegetables the same lines may be followed as explained before in the collection of fruit, except that three marks would be quite sufficient. The difference in value of say twelve varieties or sorts of high-class vegetables, or the expense and skill required for production, varies so little that the three marks or twelve points should be found sufficient. I will point out what sorts are entitled to the different marks, and the qualities which constitute first-class vegetables. We will consider the following twelve sorts—Cucumbers, Tomatoes, Vegetable Marrow, Celery, Leeks, Onions, Cauliflowers, Cabbages, Carrots, Turnips, Peas, and Potatoes. Perfect specimens of the first six should be assigned three marks, or the full number; these require more labour and skill in production than most kinds, and are equal to, if not superior, to any others grown for table use. Someone might be apt to say it is not as difficult to grow good Carrots and Turnips as Leeks or Celery. I would say, No. Give the former the proper soil, sow the right seed, and comparatively little more trouble is wanted. It is not so with the others; they require careful treatment in the young state, with constant attention and manipulation as they grow. If supposed to be out of season at an autumn show we have to say they are used by some people at that time, and if not, will keep till wanted, and please all the better from the extra attention secured. The last six mentioned should have two marks, or eight points for the finest examples, being all about the same order of merit for domestic purposes, and equal as regards the trouble and expense in cultivation.

I will now refer to the points to be observed in judging the kinds already named. The Cucumber should be fresh, straight, smooth-skinned, free from ribs, dark green; spines black, equally divided over the rind, with bloom undisturbed. If two are shown should be as near equal in all their points as possible. The Tomato should be of a bright red colour, clear skin, uniform in shape, firm and free from blemishes. Vegetable Marrow, if cut, should be judged according to their condition for present use, with these three points as to quality—thickness of flesh, thinness of skin, and smallness of core; if uncut, then the outward appearance and pressure of the thumb will be the guide. Celery is a very useful and highly valued vegetable, requiring much labour to have it in good condition in the month of August. The head should be round, compact, free from split stalks, which should be solid and smooth. When cut the centre should be white, solid, without indications of bolting, and well blanched.

The Leek, to have it large and well blanched in autumn, requires as

much attention as Celery. Very little difficulty is experienced in judging Leeks. The only point to notice is the length and thickness of the blanched part, which should be firm, round, and clear. Onions should be large, well ripened, with small neck and clear skin. The properties of Cauliflowers are size, closeness of "curd," colour pure white, a vertical section representing half a circle. The good or bad qualities of Cabbage can only be ascertained on cutting. Often the best looking are worthless when examined in this way. The inside should be yellowish, inclining darker to the outside, which should be green. The Carrot succeeds only in certain localities, and baffles all attempts to grow it well in many places. The points of quality are colour dark red, clean skin, free from fibre, smooth, brittle, tender, and sweet to taste. The Turnip has its peculiarities of growth like the Carrot, and requires a certain kind of soil to grow it well. Some people prefer the white to the yellow. The former is more a summer vegetable than the latter. The form should be round, with small tap root, clean skin, no green around the top, which should be small; inside solid, free from stain; skin thin, flesh tender and sweet.

The Potato has also to be cut to find out its quality. It is said a rough skin indicates and may decide that point; but such is not always the case; and then the same sorts are different in quality at different places. Two or three years ago I was judging at a show on the Fife coast. When we came to the Potatoes—I think it was the best twelve that was wanted—my partner at once selected Grampian. I offered no objection, seeing he was so enthusiastic. We next came to find the best six. He again selected the Grampian. I then asked him why he was so partial to it. He said it was the best Potato he had. I rejoined it was the worst I had, and put it away altogether, but I had to give in. We next came to the best round, the best coloured, and several others, all which had to go to Grampian. We learned after that they all belonged to one man. The following year the competitors were nearly all showing Grampian, but the judges being changed it found no favour, to the dismay and disappointment of many exhibitors. We should not judge varieties simply as we find them in our own locality, but as they are presented to us at the exhibition table by a thorough examination. When cut, we ought to find in the Potato a close texture and clear colour, all of one shade; the skin may be rough or smooth, but thin, and free from specks or blemishes, should be ripe and sound.

PLANTS.

Tables of plants are now becoming common at our shows, taking the place of the large overgrown specimens we used to see. There seems to be amongst judges and exhibitors different views, different interpretations upon the wording in schedules regarding tables. It is generally thus—"For the best table of plants so many feet long and wide." A competitor may take this view of the announcement, and suppose whatever sort of plants he uses the chief aim should be to have the table look well as a whole. The judges may take a different view, and award the prize to the table where the object has been to have the individual plants look well, and form a more meritorious group from a cultural standpoint; or they might look to the display of flower and foliage produced by plants, the majority of which are very small and without any indications of high culture. It would be of great advantage to competitors if they were certain of the lines on which the tables were to be judged, so that any regret or dissatisfaction might be avoided. Where effect has no part in determining the result of any competition the wording may be changed in this way: "For a table so many feet long and wide of the best plants." There would be no mistake on the part of any exhibitor. He would see at once what was required of him. In classes where quality and effect are combined, a very difficult task is given to the judges. Tastes are so different, and the difficulty of balancing the two properties to be dealt with so great, that the desirability of separating them, "thus forming a clear issue for decision," might be considered as advantageous to all. In judging tables of plants two or three matters require special consideration. First, the general appearance and healthy condition of the plants. Second, the quality as measured by the commercial value, and the labour and skill expended in the cultivation. Third, the diversity or variety in the collection, both of flowering and foliage plants. These can be judged in the same way as fruit and vegetables, by allowing so many marks for each of these three conditions, or by grouping all the plants of equal value together, and allowing the number to each group according to their merit. It would be impossible to lay down rules for judging tables unless the numbers and varieties were specified, the subjects are so numerous, and the standard of perfection undefined, consequently that part would have to be performed by the judges as a prelude to their labours.

Judging tables of plants for effective arrangement is a very simple proceeding, as it resolves itself into a matter of taste; but then a decision is not easily arrived at, as I have said before, tastes differ so much. What is pleasing to one is offensive to another. However, people generally appreciate what is natural and graceful, and have a dislike for what is stiff or artificial. In consequence, the former arrangement should be kept in view by competitors. The selection of plants bears a very important part in the success of any arrangement. Slender, elegant-foliage plants should form the principal portion, chiefly green, with colour enough to take away the sombre appearance, then the whole should be interspersed with flowering plants to give a cheerful sprightly aspect. There is no class of plants so well adapted for this purpose as those from the stove. A few common or greenhouse plants may be used to good purpose, but as a rule the denizens of the tropical forest are the best, consequently the richest tables do, with ordinary taste and skill in arranging them, prove the most effective.

A design in miniature of the natural habitats of those plants, with graceful Palms and Tree Ferns shooting out from an undulating bed of Moss and Fern, with clumps or single plants as a representation of under-wood, a few Orchids peeping out from the foliage or hanging from the stems of the taller plants, the graceful arching spikes form an exhibition unique and pleasing. Tables in this style should be encouraged by the judges.

Specimen plants are generally well understood by judges and exhibitors, the only doubtful point being size. Extra large plants should not have favour merely in virtue of size, most allowance should be given to those of medium growth in the best condition. The same unanimity does not prevail with regard to table plants; different men judging the same would often reverse each other's decisions, and chiefly in connection with the height. There ought to be a recognised standard as a guide in the matter, and the height I gave when reading a paper on these plants some years ago—viz., 20 inches from the table, I see no reason to alter. This does not imply that every frond or tip of leaf should be confined to this height, but that the main body of the plant be confined as near as possible to it.

I will refer to stands of cut flowers simply to show how they can be judged correctly by the same system advocated for the other collections. In selecting the Rose for this purpose I do so because it receives an extra share of public patronage, and the majority of people know the properties of the Rose better than many other florists' flowers. The combination of qualities which constitute a first-rate Hybrid Perpetual Rose are thick broad petals, smooth at the edges, glossy and fragrant, high and full in the centre, describing a circle round the edge, the petals thickly set and regular, so full as not to be loose. They should not be shown in the bud, as some inferior Roses look well when about half open, and would be considered worthless if fully expanded.

A few weeks ago I met a nurseryman belonging to this district, on his way home from officiating as judge at a Rose show. He commenced to speak of that show and judging. I asked him how he proceeded with the judging of two stands of Roses if, on inspection, they seemed to be nearly equal. He said they began at one end of the stands, took Rose for Rose, putting them against each other. If the one was better than the other that told as a point in favour of the stand to which it belonged. This is a very common system of judging cut flowers, but one that is wrong, in so far as it only supplies the number of best blooms in the stands, and not the real value in the aggregate. One bloom in either stand may possibly be as good and ought to count as much as two in the other; then if it should happen that this extra good bloom be taken against an inferior one, the balance of merit is lost sight of. A better way, if that plan is carried out, is to select the best in each stand, and put them against each other, when a true estimate of their value can be formed.

In accordance with the plan of judging I have proposed, I may conclude by showing how it is equally applicable to cut flowers. In taking the merits of two stands, the best bloom or blooms, if there are several equally good, should be allowed the maximum number, or three marks, equal to twelve points, the next to receive two marks, with the number of points added, which would represent their true value in relation to the highest standard, and so on deducting points, as the remainder recede in quality from each other, sum up the whole and find the difference for the prizewinners.

I may not have made my system of judging plain enough to be understood by all; but any subsequent discussion may tend to clear away any misunderstanding, and place on a favourable footing a system which, if adopted, would secure for the judges a means whereby they would be able to administer equal justice to all shades of difference in quantity, quality, or appearance.

TREE PÆONIES.

Is it not surprising that while the herbaceous Pæonies, *P. edulis* and others, are well known as among the most showy of garden plants, the tree *P. Moutan* and its varieties are practically strangers to our gardens? This is, however, an undeniable fact, especially so of English gardens, and how to account for their absence I know not, for we have no greater ornaments than these in the hardy garden during May and June, and it must be from their being insufficiently known and their requirements not being well understood that their absence is so noticeable. It is, therefore, with a view of awakening the older and more experienced of our gardening friends, who must know something of this valuable group of plants, that I am for a short time directing the attention of your readers; and while imparting the little I know respecting them, in the hope that some may be benefited and others induced to record their experience, I trust that the subject of these remarks may yet meet with the appreciation and more general use that they deserve at our hands.

Though among the grandest of our shrubby flowering plants in spring time, the present is a most important one in their propagation, which is the main reason for my now referring to them. In consequence of their flowering early in the year, it not unfrequently happens that both foliage and flower buds are disfigured, and the latter often materially injured, by our late spring frosts. This is especially the case after having passed through a winter of extreme mildness, and in consequence excited into growth much earlier than usual, only to be arrested by harsh biting winds and nipping frosts. This particular combined with their slow growth may have done much to mar their progress; still there are places and positions sufficiently sheltered and well drained to give them the little protection they require, together with the variety of other uses to which

they may be put, that the above-named drawbacks are as nothing compared with the grandeur and usefulness of these uncommon plants.

These shrubby Pæonies are natives of China, and belong to the natural order Ranunculaceæ, the genus taking its name from the physician Pæon, who, it appears, first used the roots for medicinal purposes. In that fine old work, "Hill's British Herbal," published in 1756, only three kinds are quoted; great stress, however, is laid upon their great and varied properties as a medicine. In common with the majority of strong-growing plants belonging to this order, they delight in a deep, rich, well-drained loam, such, for example, as a loam of fair depth overlying a gravelly subsoil. They delight in abundance of moisture during the growing season, and a good and perfect drainage. Anything approaching stagnation, or a position in which they are flooded in wet seasons, is sure to end with unsatisfactory results, if not ultimate death. On the other hand, a continuously dry hungry sandy soil is not suited to them, though this latter is even better than an excessively wet one. Like their sisters, the forms of *P. edulis*, they are deep-rooted subjects, and in cases where there are large established bushes their roots will have penetrated a depth of 3 or more feet. I have said large established bushes; these, however, will not be very numerous, though we have on record some examples of rare size, and I can myself bear testimony to some specimens fully 30 feet in circumference, one of which this year has had upwards of 200 splendid blooms; some of these would be as large as an ordinary dinner plate. Many years must necessarily elapse ere plants attain such enormous proportions as this, and it is questionable whether those who were at the expense of planting them would ever live to see them in all the glory which they attain in their native haunts, and where they oftentimes reach 8 or 10 feet high, though I have never seen them more than half that height in England. In continental gardens they are cultivated on a comparatively large scale, and are offered annually in great variety. Nearly fifty years ago the Chinese are said to have been possessed of over 300 varieties, but whether this be true or not, we have ample proof of their possessing them in quantity.

The best time for planting them in the open ground is from the end of August to the end of October, and once well planted allow them to remain undisturbed, save an occasional loosening of the surface and mulching in severe weather. They are best suited for the shrubbery in such places where they will not be overcrowded by other things of quicker growth, or for isolated positions on the lawn; but in whatever position they are placed there should be plenty of room for ultimate development, consequent upon their being impatient of being moved after once they are well established. In this respect they are very much like the herbaceous section, which in large plants can only be removed by much breakage and injury to their long tapering and extremely brittle roots, and which is sure to interfere with their flowering the ensuing year.

It has been suggested that these tree Pæonies, when planted in the open ground, should be protected in spring by canvas or mats against frost. This may sound very well at first, though I do not in any way agree with it in practice. Rather let their protection be in the shape of sheltered positions, as I have previously said, than to resort to any covering which, while having the desired effect in one way, not unfrequently tends to make them the more delicate and susceptible to cold than when left fully exposed. So far as my experience goes, I consider a severe winter as conducive to their well-being, especially so if the wood has been well matured the previous summer; indeed, I have failed to notice any difference between these and any other hardy deciduous shrub, save that they may be somewhat later in flowering. I have known them to withstand from 22° to 25° of frost (and we seldom get more for any length of time together) without injury. Some ten years or so since the Messrs. Rollißon of Tooting had a good collection of these plants, numbering about 100 kinds more or less, so far as I can remember. These were in charge of the writer, and consisted of some exceptionally large forms. For my own convenience I carefully described them, but my notes referring to them I have unfortunately lost. I believe this collection at that time to be among the best, and many were as varied and gorgeous in colour as the best forms among the herbaceous kinds.

The original Pæonia *Moutan* and its varieties were introduced from China in the year 1789, and of which the following were among the best:—*P. M. papaveracea*, with large single white flowers, beautifully marked with purple spots at the base of each petal; *P. M. Banksi* (this is a double variety, and when fully expanded the blooms are 8 or 9 inches across; the petals are slightly tinged blush, nearly white at the edge and purplish red at the base); *P. M. albida plena* is said to be a seedling raised at Arley Hall in Worcestershire from seeds of *papaveracea*, flowers are very double, rather pale, and suffused with purple at the base; *P. M. Humei*—in colour this is almost the same as *Banksi*, the flowers are double with a tuft of long petals rising from the centre of the flower. Among the more recently cultivated varieties the following are the best:—*Avocat Guillon*, very large and full, white, slightly tinted lilac, lilac centre, and blotched with carmine; *Beauty de Twickel*, dark carmine, large and full; *Comtesse d'Ansembourg* pure white on mauve-shaded ground; *Gloria belgarum*—this is probably the grandest variety extant, and was raised by M. Goethals of Ghent. I am not quite certain of the exact date of its emerging into commerce, but some nine years ago the exceptionally high price of 22s. was asked for a plant of it; the colour is a tender rose tinted cerise and shaded with carmine and deep crimson. *Jules Perlot* is a magnificent rosy lilac; *Madame Jules Orban*, fine white, with violet blotch; *Madame Stuart Low*, cerise red, with white tips; *Modeste Guerin*, another very fine variety, having enormous flowers of a bright dazzling fiery red, very full and globular in form; *Souvenir de Gand*, bright vermilion, very large

and full; Arethusa, rose, shaded purple, full, vigorous and fragrant; Athlete, lilac and white, a fine double flower; Triomphe de Gand, bright pink, shaded with salmon red, large and full; Rosea odorata, beautiful rose, large and fragrant; Lilacina plenissima, soft lilac, very fine; Jewel of Chusan, grand flower, globular in form, of snowy and transparent whiteness—this is an acquisition to this valuable group of plants; Grandiflora gigantea, cherry, very large and full; Ida, milk white, a very distinct and pleasing kind; Van Houttei, deep carmine rose, and brighter centre, edged white, fine. To these may be added a great many more, but I think they will be sufficient to prove that great diversity of colour has long existed in this truly magnificent genus, of which it may be remarked there is but one species. It is also worthy of note that while the Chinese varieties are all, or nearly all, double, the Japanese are mostly single, or at the most in some cases semi-double.

No traveller, probably, has done so much to popularise these plants as the late Robert Fortune, to whom we are indebted for the majority of the original kinds introduced from China. While penning these notes I feel how inadequate is our conception of the grandeur and hold characteristic beauty of these shrubs, for what have we till the Rhododendrons commence flowering that can in any degree compare with these for a brilliant and striking effect? and to see them several feet high, with 200 or 300 giant heads of flowers would be something new to not a few of us in these modern times. While having fully realised the diversified beauty of a few blooms on a plant of many of the cultivated forms, I am the more desirous of yet meeting them in specimen form. Here I would ask the reader to imagine that noble variety to which I have previously alluded, Gloria belgarum, which is said to have blooms over a foot across. Imagine such a one to have attained a height of 4 feet or 5 feet, and a circumference of 30 feet, having 200 blooms upon it, what a gorgeous picture would be presented! and though imaginary in the case of this one at present, it is by no means impossible for such things to be realised in English gardens, the only thing being a question of time after once fairly established. Speaking of fine specimens reminds me of a very fine one in a riverside garden at Cookham, under shade of the Cliveden Woods, which is about 10 feet in diameter, and was a grand sight when in flower last spring.

But now a few words as to their propagation, which may be accomplished in several ways—by division, by layers, by cuttings, by grafting, and from seed. The two last-named are the best, and the latter the only way in which new kinds may be raised. To be able to practise the first method—i.e., division, the original plants would have to be of fair size; and though it may be done, I do not recommend its adoption generally, since for these plants I am a strong advocate of the let-alone system. The second means of increasing them—by layers, may be performed about October, or even earlier, much in the same way as the layering of all deciduous shrubs is performed in autumn, which is so well known as to need no further comment. The next means which may be employed to increase the stock of these plants is from cuttings. These are best from single eyes, and if taken in the early part of January while the buds are yet dormant, and inserted after the manner of Vine eyes, and placed in slight warmth, a good per-centage of them will form roots. —E. J.

KITCHEN GARDEN.

Globe Artichokes.—These are over now, but they have been extra plentiful and good this season. Some do not care for them, others are very fond of them, and where many changes of vegetables are desired a good number of them should be grown. They need not have the best position in the garden, as they will do very well almost anywhere, provided the soil is deep and moderately rich. Many are in the habit of planting them in spring, but they may be very successfully transplanted now. We prefer autumn to spring planting, as the plants will be partially established before winter, and grow very freely next spring. Where the plants are very close together every other one should be taken and planted elsewhere. The strongest suckers which are pushing up from the sides of the plants are good for new plantations. They should be taken off with a root and planted carefully rather deep and 3 feet apart each way. Before frost comes all that have been transplanted now must be mulched well round the neck. Where planting is not necessary cut all the old fruit stems off down to the level of the ground, clean the surface between, and allow the young growths to develop freely.

Harvesting Onions.—Spring-sown Onions are a most satisfactory crop this season. Failure from any cause is quite the exception, and the grub which plays such havoc some years has been comparatively harmless this time. The plants were somewhat late in forming bulbs, but of late they have fully made up for lost time, and the crop is now a good one, indeed above the average, and it only remains to harvest it properly to make a constant supply of good Onions quite sure throughout the winter. The whole of the bulbs should be drawn up and laid down on their sides for a few days on the ground from which they were pulled. They should afterwards be spread out on a dry pathway for about ten days, and then they may be taken under cover and stored permanently. Should the weather

be wet and unsuitable for drying them in the open they must be put under cover, an open shed or similar place being good for the purpose. They need not be cleaned before being dried, but before storing all the loose skin, superfluous top-growths, and very long roots must be rubbed or pulled off by the hands. The largest may be placed by themselves to be used first, and the smallest be kept to the last, as bulbs about the size of a hen's egg keep much longer than any 1 foot or more in circumference. While drying they should never be more than one layer deep, but when stored they may be heaped on the top of each other, as if they are dry no harm will result from this.

Earthing-up Celery.—Much of this useful vegetable will soon be required in the kitchen. Earthing-up should have early and careful attention. Those who do not approve of earthing-up as growth goes on, but do not touch it until growth has been completed, must earth up now if it is desired to have it well blanched and tender when used. Take all the short outside leaves off. Tie those remaining firmly up near the top with a piece of old matting, break the soil on the edges of the trenches down fine, and work it in between the plants. The rough part may be put in between with the spade, but the hands should be used to press it round the stems, and on no account should the earth be allowed to drop into the centre or amongst the leaves, but the matting helps greatly to prevent this, and when earthing is finished it can be taken off. Early plants which have been earthed-up once or twice may be finally attended to, and plants which have run to flower prematurely should not be thrown away, as the leaves of them may be used in the kitchen in the place of the best produce.

Leeks.—The greater amount of white stem these have the better, indeed they cannot have too much, and to have them in the finest possible condition they should be well earthed up, the soil being placed close around the stems as often as it can be conveniently done without covering too much of the leaves.

Peas.—August and September crops have been fairly good, but we have seen them better. Now the pods are not filling rapidly, and we have almost seen the last of this much-valued crop for another year. Birds must be prevented from spoiling the full pods, and where rain has not fallen freely lately water heavily with guano water if possible, as this is more heating and stimulating than farmyard manure at this season. Sutton's Latest of All and Laxton's Omega have again done exceedingly well as late sorts.

Beans.—The Broad varieties are now finished. They are not at any time very choice, but they make a good change, and early in the spring they are delicate and acceptable. Any ripe pods on good sorts should be gathered and preserved for seed, and clear all the old plants away. They take much nutriment out of the soil, and any ground they have been on must be manured before another crop goes in. Runner Beans have been grand, especially those rows which were mulched before the dry weather set in. The small pods will swell yet for some time to come, but late ones in blossom will not prove very useful. Where tender pods are very abundant they ought to be gathered and salted for the winter. Our cook does some bushels every autumn about this time, and they are much valued in winter. The pickling process is very simple. They are mostly placed in stone jars with wide mouths. A layer of pods is put at the bottom, a little salt is then shaken over them, another layer is put in, and more salt over them, and so on until the jar is full, when a piece of cloth is tied over the mouth, and they are placed anywhere about the larder or scullery until wanted. Of course when taken out they are salt, but after being steeped in water for a time and boiled they are generally pronounced uncommonly good. Pods which have become too old for use on any row should be gathered at once if they are not required for seed, as they will hinder the young recently formed ones from coming forward. Where Kidney Beans must be supplied all the winter make sowings of Osborn's Dwarf Forcing in any vacant pit where a little heat can be turned on if wanted, and sow a quantity of seed in 3-inch pots to secure a hatch of plants for fruiting in pots in November.

Radishes.—The China Rose is the best of all sorts for winter. A year or two ago we sowed it about the end of August, and by the end of November the roots were 5 inches and 6 inches round, being too large and too early; but if sown now they will be right, as three weeks or so makes a vast difference in the sowing of any vegetable at this season. Put them in rows 1 foot apart, sow thinly, and give them a sunny position. They will keep up a supply from November until April.

Mustard and Cress.—For a considerable time these have been easily secured, seed scattered on the surface of the soil anywhere producing a crop; but this will not do now, and indoor culture must be resorted to. A great heat is not wanted. They will do in a frame or under a handlight for a time, and if the seed is sown in very shallow boxes or trays, with a little soil underneath, they can be transferred to any temperature as the state of the weather and the demand dictates. This is a good way of keeping up a supply throughout the winter in all gardens.

Autumn-sown Cabbages.—This is the most important of all autumn crops, and cannot be too well attended. No attempt should be made to allow all the young plants to remain in the seed bed until the whole of them are ready for planting, but as some will become large and ready for planting much sooner than others, these ought to be drawn up and planted at once, and more rows can be put in now and again as the plants are ready. Ground from which we have cleared the spring Onions has long been a favourite position for autumn Cabbage. They are planted without digging or manuring, and always grow robust and fruitful. The ground is hoed and cleaned before planting, and the

large sorts are put in 18 inches apart each way, and the small-growing sorts 1 foot or 15 inches. Examine recently stored Potatoes, removing any that are decaying. Keep Asparagus stems tied firmly up to the last. Hoe between the young autumn-sown Onions, Spinach, Turnips, &c. Do not allow weeds to make headway. Earth up late greens, and give all winter crops the fullest attention.

FRUIT FORCING.

VINES.—*Earliest-forced Vines.*—To have Grapes ripe by the close of April and the beginning of May the Vines should now be pruned and dressed at the earliest convenience, and prepared for closing the house in November. If the houses have been kept free from red spider and other insects a good washing with warm soapy water will be sufficient, in addition to any limewashing of walls, &c., as many healthy Vines are ruined by the barbarous practice of scraping, scrubbing, &c., when there is no necessity for it. When, however, the Vines have been infested with red spider, scale, or mealy bug strong measures should be adopted. The best winter dressing is petrolum, a wineglassful to three gallons of water, syringing the Vines so as to thoroughly wet them in every part. The whole of the house should be treated in this manner, and repeated when it has dried. The syringing should be again performed when the house is closed for forcing. The proper and most effectual time to deal with the enemy is through the spring and summer, especially in the case of mealy bug, when every insect that has escaped the winter dressing should be destroyed by the application of methylated spirits. Take advantage of fine weather to have all outside borders put in order by thoroughly clearing them of all old mulching material, and insert surface soil down to the top-dressing with new compost, consisting of rough turfy loam, charred refuse, and bone dust thoroughly mixed and used in a dry state. Beat it down firmly with the back of a steel fork, and cover up with 3 or 4 inches of fresh stable litter for the present. The borders should have the full benefit of all the rain that falls up to the end of October, the covering being increased in time to protect from frost and snow.

Late Houses.—Although such varieties as Lady Downe's, Gros Colman, &c., are sufficiently ripe for exhibition purposes, they will need to remain on the Vines a considerable time before they are fit for removal to the Grape-room, at least a long time to bring them into the best possible condition for dessert. Up to the end of the present month a good quantity of foliage is desirable on account of the colouring process; but as the days are shortening and the nights are getting cold, all lateral growths should be removed to admit of a free circulation of air through the bunches and main leaves, which must be kept clear of the glass. Where there is a house of Black Hamburgs ready for cutting the supply will be kept up until the Alicante, &c., come in in November onward, leading to Lady Downe's, which is the best for keeping up to May. To have Gros Colman in perfection it should not be cut until the Vines are quite leafless, then being bottled and kept in the Grape-room for at least a month, sufficiently dry to prevent the stalks damping, and then its flavour is so much improved that it may be ranked amongst the finest Grapes for use from January to March, its earthy flavour disappearing with keeping.

CUCUMBERS.—Maintain a genial temperature in this department, and ventilate freely during favourable weather, which will cause the plants, other points being attended to, to make a short-jointed and solidified growth, which is the foundation of a good supply of fruit, success being dependent upon healthy development. Close the houses early in the afternoon, or from two to half-past two o'clock, being guided by the weather and the aspect of the house, damping the walls, paths, and bed at the same time. Add some fresh soil to the sides of the hillocks or ridges of the plants recently transferred to their fruiting quarters, and of the same description as that in which the plants are growing, continuing to do this as the roots push through the soil, which produces a decided improvement in the plants. As plants have now reached the third and fourth wire and have been stopped, the laterals resulting will need to be trained regularly over the trellis, and all fruit showing should be removed at once, provided a supply of fruit can be obtained from other sources.

Plants in full bearing will now be considerably improved by receiving a top-dressing of three parts light loam and one part well-decomposed manure; after which, if dry at the roots, they should be watered with tepid and clear water, it not being advisable to apply liquid manure until fresh roots are formed and pushing well into the new soil. A temperature of from 70° to 80° during the day must be maintained, and 85° with sun, closing early so as to raise the temperature to 90°, the night temperature being kept at 65° to 70°. Ventilate freely on all favourable occasions, and syringe twice a day in bright weather. Let the stopping, thinning, and tying be duly attended to, and keep the foliage sufficiently thin to allow of light having free access to the principal parts, overcrowding and overcropping being the greatest evils in fruit, and especially Cucumber cultivation.

Plants growing in frames will require to have the linings attended to weekly or fortnightly, as may be necessitated by the state of the weather and the condition of the fermenting materials at the time work is done. When the plants in these structures require water at the roots let it be given in the early part of a sunny day, so that the foliage may become dry before sunset, and keep a guard against damp by ventilating in the early part of the day.

PLANT HOUSES.

Geranias.—If these are not already in their largest pots they should be placed in them without delay. For most purposes of decoration these

plants are best grown in 5 and 6-inch pots. The pots should be liberally drained, and the plants grown in a compost of loam and leaf soil in about equal proportions, with about one-seventh of manure added and a liberal quantity of coarse sand. After potting the house in which they are grown should be kept close and the plants lightly shaded from bright sunshine until they are rooting again freely in the fresh soil. The atmosphere and stage upon which they are standing should also be kept moist, but care must be taken not to allow water to fall upon their beautiful foliage, or it will be brown and injured. These plants undoubtedly do best if stood where a little heat can be maintained beneath them, and where cocoa-nut fibre refuse or other moisture-holding material is employed. They must, however, be arranged close to the glass even if the first-mentioned position cannot be accorded them. They will be found to succeed very satisfactorily on a shelf if due attention is paid to the supply of moisture. Care must be taken in giving water until they have filled their pots with roots, when a plentiful supply should be given, and occasionally soot water in a clear state. Bright sun only should be shaded from them, every ray of light possible being necessary to insure a sturdy, dwarf, compact growth.

Gloxinias.—These are very useful in autumn both for decoration and supplying cut flowers until nearly the close of the year. Healthy late seedlings in small pots will prove to be very useful if transferred at once into 4 and 5-inch pots in a compost of loam, one-third leaf soil, a little decayed manure, and sand. They will be found to do best on a shelf close to the glass, where a night temperature of about 60° to 65° can be maintained. These plants will soon grow freely and gain strength in the temperature indicated, and in due time produce a good quantity of flowers. All plants that have ceased flowering should be gradually kept dry at their roots in order to mature and ripen their roots for another year. This must be done gradually, or they will decrease in size and strength. Plants that flowered very early in the season and have enjoyed a long period of rest in a cool place may have the old soil shaken from them and placed in boxes of leaf mould. In a moist temperature of about 65° signs of growth will soon be visible, and when the shoots have extended a few inches they may be potted singly into as small pots as possible. These plants are so easily grown that with care and judgment their useful flowers may be had the whole year round. Gloxinias are well worth growing through the winter, although it is not possible to produce them in such excellent condition as is the case during the spring, summer, and autumn months.

Caladiums.—Although these fine-foliage plants are not grown so largely as formerly, they, nevertheless, find a place where a great variety of plants are required for furnishing purposes. Annually many of the tubers are lost principally through the careless manner in which they are treated after their foliage naturally commences to fade. They must not be pushed on one side and left to themselves directly their term of service for decoration has been completed. They must be watered and tended with the same care afterwards as when growing, until their foliage naturally dies. This must be accomplished by slightly drier conditions both about the roots and in the atmosphere in which they are placed, until water can be entirely withheld from them. They should during the process of ripening enjoy full light, and no lower temperature than 60°, under which conditions they will thoroughly mature their tubers and pass the winter in safety. After the whole of the foliage has been ripened, if the soil about the roots is kept perfectly dry they will rest safely in a temperature 5° or 10° lower.

Urceolina pendula.—Under careful treatment this old favourite can be had in flower in succession for at least six months out of the twelve, and this during the most dreary months of the year when indoor flowers are not too plentiful. Plants that made their growth early in the season under the influence of light and heat will have been thoroughly ripened and resting under cool conditions for some time. These, if stood in a warm house for a few days, then given a little water, will soon show signs of activity, and their umbels of drooping yellow and green flowers will soon appear. By a judicious system of growing batches of plants at different seasons, resting and starting them successively in heat, there is no difficulty in having plants constantly in flower over the period indicated. After flowering the bulbs should be repotted in sandy loam, a little manure, and sand. A little leaf mould is also beneficial, as it encourages a free and quick development of the foliage. Water should be applied carefully after potting until the plants are growing and rooting freely.

Winter-flowering Plants.—Such plants as Poinsettias, Euphorbias, Begonias, and others growing in cold frames must be watered at their roots with great care after this date, or the latter will probably perish. Shading must be dispensed with, and every ray of light admitted to harden and ripen their wood, for upon this depends whether they flower well or the reverse. The frame must now be closed at night, and air admitted during the day with greater care than has been necessary up to the present time.

THE FLOWER GARDEN AND PLEASURE GROUND.

Propagating Pansies and Violas.—The past summer has been much too hot to suit these, and in many gardens where the Violas are largely bedded out they have failed conspicuously. They require a rather rich soil and plenty of moisture, and then they are surprisingly effective. Since good soaking rains have fallen they have commenced to grow freely, especially from the main stem, and the soft flowerless shoots are the best to make into cuttings. Failing these the tops of the old flowering shoots may be put in, and these will eventually form bushy useful plants. No bottom heat is required, and all that is necessary is to form a firm shallow bed of half-decayed leaves inside a frame, on this disposing about 4 inches

of light sandy soil, or a bed may be formed for handlights to stand on. The cuttings may be made about 3 inches long, cutting them to a joint, and trimming off the lower leaves. They should then be firmly dibbled in about 3 inches apart each way, watered, and kept close and shaded till rooted, when they ought to receive abundance of air in order to keep them hardy, and also to check luxuriant growth till the spring, at which time they will require to be transplanted to a more roomy bed. Pansies raised from seed in June, or from cuttings in July or August, and intended for winter bedding, ought not to be crowded together till such times as the flower beds are ready for their reception, but should be thinned out and replanted in beds of rather light and good soil, from which they will readily transplant in October or November. At that time also many old plants that have been cut over recently will have formed compact tufts of growth, and these may safely be divided and replanted for spring flowering.

Antirrhinums and Pentstemons.—These can now be had in great and good variety from a packet of seed, and seedlings are invariably the most vigorous. For early blooming the plants should be raised in the autumn, and if newly ripened seed is at once sown in pans of fine sandy soil, very lightly covered with more of the same soil, the pans either being covered with a square of glass or stood in a handlight and kept properly moistened and shaded, the seedlings will soon appear in hundreds. When large enough to handle they should be pricked out thinly in pans or boxes of light good soil, or in a frame. They will need but little protection during the winter, and be planted out where they are to flower some time in the following April. If it is thought desirable to increase or preserve the stock of any good sorts of either named or unnamed *Antirrhinums* and *Pentstemons*, no time should be lost in putting in the requisite number of cuttings. The former are the most easily struck in a mild hotbed, as recently recommended for *Verbenas*. The soft side shoots should be preferred, and these if slipped off and not more than 4 inches long will not require to be cut to a joint. They may be struck thinly in either pots or pans of good sandy soil, and when well rooted should be hardened off and wintered in a cold frame, finally planting out in the spring. *Pentstemons* are best struck in a cold frame or handlight placed in a cool shady position, and kept close till the cuttings are rooted. Later on they may be either potted or boxed in order to prevent their becoming unduly hard and root-bound, but they must be kept in a cold frame or pit, and planted out in the spring.

Carnations, Picotees, and Pinks.—Directly it is found that either the layers or cuttings of these are well rooted, they ought in the latter case to be properly hardened, so that all can be planted out where they are to bloom next season. All succeed best in beds raised slightly above the ordinary level, and in most cases an addition of fresh loam, horse droppings, and road grit will be good. The layers ought to be very carefully separated from the parent plant, and as much soil preserved about the delicate roots as possible; those raised from cuttings being also very carefully handled. The *Carnations* and *Picotees* may go about 12 inches apart in rows, the *Pinks* rather closer, and 6 feet is a good width for the beds, a 12-inch path separating them.

Saving Seeds.—*Pentstemons*, *Antirrhinums*, *Nasturtiums*, *Poppies*, *Lupins*, *Lobelias*, *Mignonette*, *Godetias*, and various other annuals and biennials are all seeding freely this season, and those who may wish to do so can easily save a quantity for sowing next season. All should be gathered directly the seeds are found to be fairly hard, and the pods be laid on dry shelves, each sort on separate paper, to thoroughly ripen the seed preparatory to its being cleaned and stored in paper bags. As a rule home-saved seeds, especially of *Stocks*, *Asters*, *Zinnias*, and *Dianthus*, seldom give such a good variety as do those obtained from respectable seedsmen, and for our part we prefer to annually purchase ours. The seed-growers generally cultivate each sort in large separate beds, and this preserves their individuality, and a good mixture can thus, if required, be supplied; whereas private growers cannot keep the sorts properly separated, and as a consequence the coarser and least valuable sorts naturally overpower the weaker choicer sorts, and the strain is much deteriorated. To save our own seeds, then, is often the reverse of being economical.

Grasses and Everlastings.—The greater portion of the former ought to have been cut and dried some time since, as if delayed till the seeds are ripe many of them would shatter, and the beauty of the *Grasses* be lost. The later sorts should all now be cut when dry and hung up in a vinery or other dry house in bunches to thoroughly ripen. All will be found very useful either for mixing with natural flowers during the winter or for placing in vases without any flowers or greenery with them. The *Everlastings*, notably the *Helichrysums*, should also be cut when dry, and before they are too far advanced, tied in bunches, and hung up to dry.

Sowing Grass Seeds.—Any bare patches may now be sown with lawn grass seeds, or new lawns may be formed and sown, and a good piece of turf be thus quickly obtained. This will be found far better than waiting till the spring, as no one likes to see bare patches, especially near a dwelling house.

combs, and provision. Young queens being those that give the greatest satisfaction, bee-keepers looking to their own interest will have seen to this important matter. Young queens do not, however, all turn out satisfactorily, sometimes through organic defects. When this is the case the queen should be deposed and the bees joined to another hive, or a young and healthy queen installed.

JOINING TWO HIVES.

The safest way to join two or more hives together when in frames is to crowd the bees on to as few frames as possible, after which break the seals of some of the combs, or sprinkle both well with very thin honey and water, or syrup containing a drop or two of oil of peppermint. When the bees are fully gorged, lift bees and frames together from the one to the other. The process with straw hives has been already described. Success depends entirely upon both swarms being gorged with honey and put into confusion.

SUFFICIENT STORES.

The bee-keeper will by the manipulation observe the amount of stores. Should these be deficient, lose no time in having the proper quantity of food supplied. A word of caution, however, may be necessary here. It is generally advised to give syrup thick at this season, which I have often seen followed with the result of bees dying with plenty of sugar in the hive, but granulated. Weight of sugar and water is a bad rule to work by, as some sugars are much stronger than others. Avoid feeding with beet sugars. Get the best cane sugar, and whatever quantity is to be dissolved, pour water on it until the water stands 2 inches above the sugar. Keep stirring until all is dissolved, and let it boil for one minute; the bees will store to the proper consistency.

FOUL BROOD.

The autumnal examination is not only advisable but necessary, so as to detect any traces of foul brood. If only a few cells are observed on the vacated combs there need be no fear, but if numerous sunken black seals appear amongst the brood, and prove to be foul brood by the brownish and sticky matter having a foetid smell, then it is better at once to separate bees and comb, putting the former into a clean hive, and the latter into the melting pot after the honey has been separated, taking particular care that none of the contents can be got at by the bees of your own or neighbours' apiary. When only a few unhatched cells are observed upon the outside combs, which may not be foul brood at all, it will be as well to excise such and anoint the place with carbolic acid, but make a thorough examination, and give the disease no quarter.

QUEENLESS COLONIES.

These sometimes cause a great annoyance from the fact that, though seemingly queenless, they are actually in possession of either an imperfect queen or fertile worker, and any queen introduced to such hives runs a great risk of being killed. To make sure work with all such hives, give them a piece of comb containing eggs and larvæ. If they are free from such pests, royal cells will at once be commenced. When they have wrought two days at these remove the comb containing eggs and larvæ, together with royal cells, and cage the queen to be introduced in the cluster for twenty-four hours. If no queen cells are attempted, then it is better to kill the bees at once.

PARTLY FILLED SUPERS.

These should be given to some hive to clean out. Where hives are not constructed for this purpose a box large enough to hold combs in frames or supers should be made, and placed beneath a hive constructed so as to admit the box containing the comb, to be slid underneath or withdrawn when necessary.

ROBBING.

As feeding with combs is apt to encourage robbing, care should be taken that no feeding is allowed through the day, nor a single drop of honey or syrup spilt or exposed. When a hive is attacked contract its entrance to that of a single bee, and if this does not prove sufficient, close it or remove it to a distance. If the former, ventilation of course is necessary, and by attending to it and giving it a flight late in the afternoon it will soon defend itself. Bees are bold enough to attack large animals, but are great cowards when attacked by bees of any hive. The attacking hive should be well smeared at the entrance with carbolic acid, but on no account should the acid be put near the mouth of the attacked hive, as it distracts their attention from the weak point.

THE BEE-KEEPER.

USEFUL HINTS.

EXAMINATION OF HIVES.

ALL hives intended for stocks should, so far as practicable be thoroughly overhauled to ascertain the condition of the queen

VICIOUS BEES.

Where bees have become vicious the bee-keeper should work as much as possible about the hive, using carbolic acid freely about the entrance until he gets familiar with the bees and has them subdued. Remember, the nearer the thoroughfare, the milder tempered they become. Wherever Carniolan queens are introduced stinging is unheard of.—A LANARKSHIRE BEE-KEEPER.

STRAY THOUGHTS.

THE advent of artificial swarming and the entire prevention of natural increase, while giving to the bee-master a certainty of profit and lessening his labour, have taken away the greatest joy he had in bee-keeping. Who that has seen the prosaic driving of a stock to found a swarm does not look back with some regret, if it be indeed a little tempered by utilitarian considerations, to the days of natural swarms? Who cannot remember the calm still day, the very air laden with the sweet odour of early summer flowers, the sonorous hum of the drone as he lazily flies, taking on this important occasion an early flight, or uneasily pacing in front of the crowded entrance; and as the midday sun throws down its gladdening heat, the bees resting for a short period from their long toil to meditate before leaving their home? And who, as the last moment arrives, and each bee, in a brief time of stillness, takes in a plenteous store to help in building up the future home—who can, I say, forget that ringing hum given by the bees as in one tumultuous throng they rush forth into the world? At last, as in a dense cloud, the swarm flies here and there; the matron queen, tired with unwonted exertion, seeks the nearest bush, and her dutiful subjects, ever mindful of the mother queen, join here with all speed.

But do we not, too, remember the darker side? The autumn night, the hole scooped out, the brimstone, and the death of those busy workers who from early spring in successive generations have toiled to gain a winter store? Does not this cloud our joy when we think of the days of natural increase, and make it more easy to forget the joy on thinking of the bees' sad end. I know old men who openly confess that as they look into the mass of sleeping bees they shudder at their deed and hate the day as it comes each year.

But—and yet another consideration is before me—when the process of driving is resorted to, great sorrow falls upon the bees and many die, crushed by the unskilled operator, who, timid perhaps, or new to his work, is unable to effect the operation in as skilled a manner as the more accustomed master hand. But let each one who tries to rescue the swarm doomed to death by sulphur, know that every bee he saves from destruction is a distinct advantage gained, and that each swarm he takes will, if added to his stocks, double their worth, and in the spring be to him a great source of pleasure, for may he not think as he sees them caper to gather the early pollen of the certain death that would have overtaken them if he had not put out a hand to save?

Let me ask each one who has to attend to bees to think of them and of their feelings, to assist them with all in his power, never to hurt one if it can be avoided, and, indeed, to consider them as friends and not as bitter foes ready to sting on the slightest provocation.—FELIX.

THEORY v. PRACTICE.

Or late years there has been a sort of mania for bee-keeping, brought about by the results of different hives of bees, and by vendors of apiarian appliances and trade journalism combined, which not only served the purpose of puffing, but by highly coloured statements induced many to start keeping bees. This is all very well in its way, but unfortunately for beginners their tutors were not practical bee-keepers, thereby leading many of the pupils into a snare. Apiculture seems to be a subject on which many have a desire to write who have little practical knowledge. They write plausibly and pleasantly enough to the novice, but to the practical bee-keeper much of the teaching is absurd—assertions without proof, and theory without practice.

There are, however, some writers sensible in their remarks, accurate in their observations, and, what makes their articles more valuable, are written from observations founded on practice, tracing cause and effect from the true source. Amongst those writers I recognise "Felix, Cheshire," Mr. G. Abbey, and "A Hallamshire Bee-keeper." I have not observed any of these writers' opinions on spreading brood, but if their observations on that be as accurate as on other things, I know their opinion will be as mine, belonging neither to the "inner nor the outer circle of students," but as bee-masters. No practical bee-keeper will ever attempt to spread brood, never finding the necessity to do so. He knows full well how to have his hives at swarming point at the proper time, and while the thermometer is still registering 4° of frost, and it would be but a poor expedient indeed to spread brood so that the outer combs should be removed the following day and "melted down," even though it was to rescue a hive from foul brood, brought about by foolish manipulation, but happily foul brood has not its origin from chilled bees.

"Manipulate, manipulate," says the theorist, "and the result will be all you desire." But success is seldom realised when the advice is taken. I am in possession of strong proof from many of the dupes on this point. "Start on a right basis and continue the proper course," says the practical man, "and let the bees alone except when they require assistance for what they cannot do themselves, and they will, as they have hitherto done, reward their owner with abundance, and you will not be disappointed."

Let me here give my own experience of my stocks this season. No

one can teach bees, but man can get many a lesson from them both for his own and their good. I put up my bees in autumn, as I always do, in a state to stand the whole season without any interference beyond cleaning the *débris* from the false floor and widening the doorway when I observe the bees attempting it. Summer and winter arrangement, beyond supering, I make no difference, nor should there be, unless it be shading from hot sun. All my stocks were filled from side to side in May, therefore there was not any possibility to spread brood, and as my hives are large the queen never gets crowded out, the hatching and laying being in equal ratio. May was frosty throughout, and there was 4° of frost on the 10th of June, and on the 12th the thermometer rose to 75°. Supers were put in and immediately taken possession of by the bees. Now, under these circumstances, would any sane person, even had it been possible, have attempted to spread brood, which would assuredly have been chilled? Where brood can be spread after the honey season is on shows a decided want of proper management during the preceding months. The number of eggs and larvæ destroyed in hives appearing in a normal state is something great, but only known to the practical and observant bee-keeper. How many more are destroyed under the manipulation of spreading the brood can only be conjectured, but disaster is sure to follow, similar to giving a sitting hen double the number of eggs she can cover.

Theory and practice are at utter variance, too, on the question of contracting hives and coddling generally. When we bury a hive on the northern side of a dry knoll the bees survive the period of immuration, but after disinterment, if the weather is cold, they fall victims to it. The same fatality attends them when a hive is contracted and the bees crammed together in little space, as well as when the door of the hive is contracted too much. Breathing space and fresh air are as essential to bee life as to human. Dryness at all times, too, is essential, and must not be overlooked. Practice shows me clearly when that course is departed from the mortality amongst the bees is greater, and the destruction of eggs and larvæ in a coddled hive is very considerable, and risky at all times of the queen being deposited.

I have a good opportunity of contrasting such matters with apiaries conducted on both principles, and one point of great importance at the present time is that where hives of different dimensions are supered—thus, where Stewarton hives are supered on two breeding-boxes, the bees take to and fill a super rapidly enough with the queen finding her way into it occasionally; but where the three-box system is carried out the supers are never invaded by the queen, while the bees from the extra space beneath will, on a favourable opportunity, build super comb when therein two boxes are idle, and the honey stored by those in the three boxes will be often double that of those in two boxes.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Joseph Schwartz, Route de Vienne, Lyon, France.—*Catalogue of Roses (illustrated)*.

Barr & Son, 12 and 13, King Street, Covent Garden, London, W.C.—*Catalogue of Daffodils and Bulbs (illustrated)*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Raspberry for the Middle of Scotland (N. B.).—You cannot grow better variety than Carter's Prolific, which has large round fruits of a deep red colour, with firm flesh of excellent flavour. It is a summer-bearing variety, and, as its name indicates, is very prolific.

Black Raspberries (R. C. J.).—The autumn-fruiting Raspberries you refer to are hybrids between the Blackberry and Raspberry, and originated from the Black Raspberry obtained at Wethersfield in Essex half a century ago. There is also a variety known as the Autumn Black, of similar parentage.

Grapes for Canada (V. A. Brown, M.D., Canada).—The Grape Dr. Hogg, raised by Mr. Pearson, and referred to in his work, is one of the finest in cultivation, and is the richest flavoured and most hardy of the White Frontignan class. The Duke of Buccleuch is a grand early Grape. You can procure both varieties by applying to Messrs. Pearson of Chilwell, near Nottingham.

Cordon Pears (A. A. B.).—For the west wall: Fondante d'Automne, Doyenné du Comice, Jewess, and Glou Morceau. For the east wall: Dana's Hovey, Comte de Lamy, Comte de Flandre, Beurré Superfin, Winter Nelis, and Huyshe's Victoria. The Pear Conference will be opened at Chiswick on October 21st, but intending exhibitors must give notice to Mr. A. F. Barron, Royal Horticultural Society, Chiswick, not later than October 14th, and consignments of fruit should be delivered on or before October 19th.

Planting Roses (Amateur).—The standard Roses will occupy the centre of the beds, and from these on each side the dwarfs should be 2 feet 6 inches, and 1 foot 3 inches from the edge of the beds, so that the beds will need to be 7 feet 6 inches wide, and we should have the Roses 3 feet asunder in the rows. Between each two standards we should have a dwarf plant, otherwise the centre will be very bare. If you grow for effect, then we should plant with dwarfs only, and the plants 2 feet 6 inches apart every way, but you may still have a row of standards between the dwarfs in the central row.

Faded Vine Leaves (Merchant).—The leaves have on their under surface a number of warts, which may have been caused by too close an atmosphere. The warts are black on the leaves sent, as if destroyed by the fumes of sulphur. The leaves in other respects are healthy in appearance and look as if they were naturally ripening. This may have been brought about by the treatment the Vines have received, and probably the ripening is premature. This fact is further borne out by the lower leaves suffering first, which is always the case when the supply of food and nourishment fails. We expect you have not given the Vines sufficient water or stimulants at the time when they needed most. If the border in which your Vines are growing is deficient in lime or other food, or too dry, remedy the evil without further delay.

Ventilating a Conservatory (Ignoramus).—The system of ventilation requires to be the same both in summer and winter—viz., air should in the first instance be admitted by the top lights, but the time of doing so will entirely depend upon the temperature and the time of year. In the winter season, or from October to March inclusive, commence ventilating by the top lights when the temperature reaches 50°, increasing the admission of air with the increase of sun heat, and open the side lights. The ventilation should be reduced by closing the side lights in the first instance, and finally the top lights when the temperature declines to 50°. In summer the same conditions are to be observed, only the temperature should be kept at 60° to 65° through the day, observing the same rules as to commencing and closing the house. The temperature in winter should be 40° to 45° at night, and 45° to 50° in the daytime, by artificial means, which will be considerably advanced by sun heat, and in mild weather. Fire heat will only be necessary to maintain the temperature named, and to expel damp, when the fire should be lighted in the daytime, and ventilation given.

Asparagus Beds Failing (H. C.).—We have known several cases of failure similar to the one described in your letter. In one large garden two or three gardeners in succession made beds at great expense, and after bestowing every possible care upon them hopelessly failed. They at last concluded that the garden would not grow Asparagus. The present gardener—a persevering man—having had considerable experience in nurseries, determined to make another attempt. He was successful, and has now beds as fine as any in the country. He did not purchase plants, but raised his own from seed, and he considers that the cause of failure in many cases is due to plants lying about for some months prior to being sent out, and are so dried with exposure that they rarely thoroughly recover. If your friend sows seed on the beds he might hope to attain success. If the soil is of a heavy nature the peat would prove rather beneficial than otherwise, but if light a liberal dressing of manure with a little clay thoroughly incorporated with the soil would be preferable. A light dressing of salt may be used with advantage.

Hardy Plants for a Small Rockery (A Youngster).—Provided the rockery is ready to receive the plants, commence operations now, as there is yet time to allow the plants to become established before the winter sets in. The drip from the trees is rather unfortunate, seeing you have such a fine exposure. However, if the branches overhang just a little it will serve as a protection from severe frosts, and will enable you to have plants that would not be quite hardy in the open. Among the plants that will grow in such a position are the following:—*Helianthemum* in variety, *Cistus crispus florentinus*, *C. halimifolius*, *Genista prostrata*, *Lithospermum prostratum*, any dwarf *Saxifraga*, *Arabis alba*, *Polygonum vacciniifolium*, *Oenothera taraxacifolia*, and *Cl. tanacetifolia*, *Alpine Auriculas*, *Saponaria ocyroides*, *Nierembergia rivularis*, *Potentilla Clusiana* and *subcaulescens*, *Plumbago Larpenae*, *Linaria pallida*, *Sempervivum Lageri*, *S. arachnoideum*, *S. triste*, &c. You might also try the *Opuntias*, *Erinus alpinus*, *Linaria origanifolia*, *Gypsophila cerastioides*, *New Zealand Veronicas*, *Sedum Arenaria Rosanii*, *S. umbilicus spinosus*, *Tunica Saxifraga*, *Dianthus Seguieri*, *Phlox verna*, and *P. amena*, *Achillea umbellata* and *Clavenua*, *Lobelia lutea*, and *Othonna cheirifolia*.

Carnations not Blooming (W. B.).—We have never found any difficulty in flowering Carnations and Pinks, and therefore cannot understand the cause of your failure from the information you supply. Since you say that the plants make plenty of growth, it would appear that the soil is suitable. Probably they are too much shaded by the high walls surrounding your garden, or they may be attacked by aphides (green fly), which suck out all nourishment from the stems. The seedlings in pots you can plant out and lay on the growths, which, if done at once, will be well rooted before winter. Probably you have failed to water the pipings of Pinks sufficiently, for with ordinary care they should root freely enough at this season. You might soon eradicate the wireworm from the soil without applying gas-lime by the following method:—Cut a number of Potatoes in half, and place into each a small stake 6 or 8 inches long. These should be inserted in the soil, leaving the top of the stake several inches above the ground, so that you will know where the traps are set, and can draw them out at intervals of two or three days. Carefully examine the Potatoes and destroy the insects found in them. By repeating this the garden will soon be cleared of these pests.

Bottling Grapes (R. H.).—Heat is only required to expel damp from the house if you keep the Grapes hanging upon the Vines. Much heat is not

necessary for this purpose if you exercise care in supplying water to the plants in the house, and ventilate it judiciously. We should have no difficulty in keeping the Grapes perfectly well in the house with the plants beneath them, but if you have had no experience in this matter your best plan will be to bottle them. This we advise you to do if the Vines are weak, as the fruit hanging upon them for any length of time after they are ripe is an extra strain which ought to be avoided. You have not said how old the Vines are, or what weight of Grapes they are carrying, therefore we cannot say whether you have overcropped them. The borders should not be dug, for this is detrimental to the surface roots, and no kind of manure will induce them to come there if you continue this practice. If the roots are some distance from the surface, remove the soil down to them either in autumn or spring, the latter being preferable, and top-dress with about 6 inches of good fibry loam, a few half and quarter-inch bones, say an 8-inch potful to each barrowload of soil. You may add the same quantity of soot or wood ashes, and about 10 per cent. of lime, or even more if you think the border is deficient in this ingredient. Top-dress annually as the roots come to the surface, and mulch afterwards with old manure.

Grapes Shanking (P. G. H.).—It is very difficult to say what is the exact cause of your Grapes shanking just about the time they are colouring. Shanking is due to one of several causes, and without an intimate acquaintance with the Vines, the soil they are growing in, the quantity of water they have received, the actual condition of the roots from the top of the border to the base, and the general treatment the Vines receive, it is very difficult to determine to which cause the evil is due. It not unfrequently arises from slight injuries to the stems of the branches and footstalks of the berries when the operation of thinning is performed. It is also due to the roots entering the subsoil or any other unsuitable material outside the real border. In deep borders with the roots a long way from the surface, where the air cannot penetrate to them, a close and sour soil, caused either by over-watering or over-feeding, is almost certain to produce shanking. An insufficient supply of food during the time when fruit-bearing is pressing most heavily on the Vines will also bring about the same results. This has been a dry season, and if you have failed at any time to give sufficient water, this alone would be sufficient to cause shanking. If you cannot find out the exact cause, lift the roots just before the foliage falls. They should be brought near the surface and encouraged to remain there. Lifting and laying the roots among fibry loam, one bushel of half-inch bones to each cartload of soil, with the same quantity of wood ashes and about 10 per cent. of lime, frequently proves a cure for shanking. You can keep the roots near the surface, after they are once there, by rich top dressings and mulchings with manure.

Vines Exhausted (Walter V. Lister).—Judging from the smallness of the berries, we should think the Vines are exhausted by the previous heavy cropping, though the unusually dry season will, no doubt, have helped the present result considerably. The roots should be examined, and the sooner after the Grapes are ripe and the wood firm the better. Remove the surface soil down to the roots, and if they are not deep do not attempt to disturb them, but, picking the soil from amongst them carefully, so as to injure them as little as possible, replace the removed soil with some fresh turfy loam of a medium texture, but light rather than heavy, and chopped moderately small, adding about a tenth of old mortar rubbish, half as much charcoal, and a less quantity of half-inch bones, the whole thoroughly incorporated. Do not cover the roots deeper than 6 inches, and make the soil moderately firm. If inside a good watering should be given with tepid liquid manure, and the surface mulched with a couple of inches of well-decayed manure. Outdoors the watering will not be necessary, but the border should be covered with dry material so as to protect it from frost. If in removing the soil it is found the roots are deep, then they should be lifted carefully, kept from the air by covering them as they are removed from the soil; and the drainage being seen to, and if defective rectified, proceed to lay in the roots in fresh compost, raising them so as to lay them in the top foot or 15 inches depth of the border, the nearest being about 4 inches from the surface. If the Vines have both inside and outside borders it is well to only attend to one, deferring the other until the following season. After the Vines are in full leafage supply tepid liquid manure liberally.

Insects on Vines (A. B.).—We have examined carefully the Vine foliage and shoots sent and fail to find any trace of phylloxera upon them. We wish you had sent us roots as well. You had better examine the roots and if you discover any small globular swellings on the fibry portions send them to us for examination. Your Vines are, however, attacked by a small insect, which is the cause of the shoots being affected as they are and the reason they have ceased to grow. It not only attacks Vines, but Cucumbers, Melons, Tomatoes, French Beans, Gloxinias, Begonias, Celosias, and many other plants besides. The warmer and moister the atmosphere is kept the more certain it is to attack plants, Vines, and whatever it prefers, and, like the red spider, it does not appear very particular in this respect. It does not spread so rapidly in a cooler, drier, and airy atmosphere. We have known Vines attacked by it commence growing freely after they have been kept cool and given more air. It frequently attacks Vines when they are in a young state, such as those raised from eyes, and either grown in pots the first season or planted out; but very rarely afterwards, for they appear to grow too vigorously. It is indeed questionable if your Vines are attacked by it another year. On whatever it becomes established it completely arrests the growth. We advise you to pinch off the affected points, and no doubt the petroleum solution you propose will destroy it. It will be necessary to shade the Vines after using the petroleum. A cultivator who has a large collection of both fruits and plants suffered severely for a few seasons from this insect, nearly every plant he grew being attacked, and he found that the best means of eradicating it was by maintaining a cool atmosphere as advised above and syringing with a weak solution of soft soap and sulphur, leaving the latter upon the shoots and foliage for some days before washing it off again.

Names of Fruits (A Subscriber).—1, Lawson's Golden Gage; 2, White Magnum Bonum; 3, Corse's Admiral; 4, Corse's Nota Bene; 5, Washington; 6, Victoria. (B. C. P., *Andover*).—1, Lucombe's Nonesuch; 2, Washington; 3, Denbigh. (J. F. L.).—Beurré de l'Assomption. (A. B.).—The specimen resembles Dunmore, but we cannot determine Plums without shoots and

foliage. (H. H. C.).—The Apple is Early Julien. (B.).—1, Brown Turkey ; 2, Brunswick.

Names of Plants.—We only undertake to name species of plants, nor varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (J. H. W., Leicester).—*Lycium europæum*. The fruits are, we believe, harmless but useless. It is curious that the fruits of Solanaceous plants that are black or purple in colour are usually poisonous, but the yellow or scarlet fruits are generally innocuous. (Perthshire).—1, *Polypodium aureum*. The dull-flowered plant is *Nicotiana rustica*, the white woolly plant is *Antennaria margaritacea*; 4, *Solidago virgaurea*. The numbers were displaced from some of the specimens, and two were quite unrecognisable owing to the fragile package having been damaged in the post. (B.).—1, *Abutilon vexillarium marmoratum*; 2, specimen very imperfect, but resembling *Lycopodium Selago*. (W. S.).—1, *Selaginella Martensi*; 2, too small and immature; 3, *Adiantum cuneatum*; 4, *Cyrtomium falcatum*; 5, *Pteris cretica albo-lineata*; 6, *Davallia dissecta*. (D. H.).—1, Not recognisable; 2, *Akebia quinata*; 3 and 4, varieties of *Cupressus Lawsoniana*; 5, *Cupressus torulosa*. (H. S.).—*Genista hispanica*. (W. C. & Sons).—*Tecoma capensis*, a greenhouse plant, which can be increased by cuttings inserted in sandy soil in moderate heat.

COVENT GARDEN MARKET.—SEPTEMBER 16TH.

AUTUMN CROPPING.

To be really useful advice should be timely, so that prompt action may be taken while it is worth while making a special effort to improve upon past work, and to apply remedies to faulty practice when they are calculated to tell home. Now, therefore, is the time to see if we are doing all that is possible to make provision for another spring—or, to be more exact, for that critical period of the year, the end of winter, when our hay and straw ricks grow smaller daily, our root heaps dwindle, and bare pastures afford no prospect of “keep” for some time to come. That is precisely the time to which we are looking forward now, and we cordially invite our readers to give the matter the attention it deserves.

Green crops for an early and successional supply of food for horses, cows, sheep, pigs, fattening and store cattle are being sown now, and it very much depends upon how this is done whether we are to have plenty of green food next March, April, and May, or are to follow the miserable suicidal practice of turning our stock out upon pastures which ought to be held in reserve for hay, and which, at that early period of the year, can hardly afford a full meal to any of the animals turned out upon it. We have already sown our Trifolium,

and would urge those who have not done so to lose no more time, but to sow at once upon a clean stubble. To show our high estimate of the value of this crop we may mention the fact of our having sown 40 acres of it now for use while it is green; but if it should not all be wanted for green food it will be turned to account for hay or for seed. Rye is the next crop, and we are sowing 12 acres of it upon the home farm, and enough upon four other farms for the requirements of each. This is the earliest green crop of the year; we have never had too much of it—seldom enough. This year we have 50 acres of it, and hope to supply horses, cows, and other stock in yards with it, as well as having enough to fold the breeding flock upon. It is off the land so early that we may plough and sow spring Tares, or hold it in reserve for a crop of Maize or Turnips. Large quantities of Rye used alone is apt to prove too relaxing, but chaffed with dry food it is both wholesome and nourishing. So, too, when sheep are folded upon it, care is taken to give them chaffed hay, bran, and crushed Oats in the troughs. Winter Oats will be sown before the end of the month. We have made arrangements to sow 50 acres solely for an early crop of corn, but if it is required for grazing in spring we shall certainly turn to it, and it will render us invaluable aid. Need we dilate again upon the obvious advantage of being able to turn to such a supply of green food in our need? and remember that farm is indeed a poor one which is not self-supporting.

Green crops are often termed stolen crops, but we venture to assert that they will soon assume so much importance in that improved style of farming which is an inevitable outcome of the present depression, as to take a leading rather than a secondary position in our arrangements for the farm work of a year. Let it henceforward be an inflexible rule that farm land shall never be idle. Well indeed would it be if farmers would take a lesson from market gardeners, and regard bare fallows as a piece of extravagance in all ordinary seasons. It is only after two or three consecutive wet summers that we can be driven to fallows for cleaning the land. Brisk and energetic action must rule our practice. There must be no period of taking our ease; we cannot afford now to finish the harvest and go partridge-shooting and cub-hunting. Save the corn, run the pigs, sheep, and turkeys over the stubbles, and then at once, without the loss of a day, up with them. Clean and burn foul weeds; set to at the autumn cropping with a clear end and aim in view, making the present the handmaid of the future, and the past the stern mentor, literally the wise counsellor, to teach us what to do and how to do it. Is it possible that any farmer who has been driven to turn his cows out of the yards in spring for lack of fodder in search of food which he knows they cannot find, not to consider if he might not have done more in the past, or cannot do better in the future for them, and, therefore, for himself? The mention of cows reminds us how invaluable Tares have been for them in the hottest and most trying period of the drought that is happily a thing of the past once more. Upon many a parched meadow have the cows been supported and the flow of milk sustained by carting a daily supply of Tares there. We began in May with the Winter Tares, which were ready before the Trifolium was done, and spring-sown Tares came on crop after crop in brisk succession. The Winter Tares were not sown till the second week in October, and we never had a better crop; it was so abundant that use could not be made of all of it in the green state, so a portion was left to ripen for seed, which will now be threshed for sowing this autumn. It is only a trifle, but little things mount up and tell in the aggregate. Do not sow Tares only as provision for cows and horses, but also for folding sheep. They thrive upon Tares, and at the same time impart fertility to the land in a much more speedy and economical manner than is possible with manure heaps and cattle yards.

WORK ON THE HOME FARM.

The farm horses have been taken into the stables at night once more, exposure now often leading to colds and rheumatism, especially in old

horses. Calves and yearlings are also shut in the yards at night, which, as well as the lodges opening into them, are made comfortable with soft litter. Store cattle have had cake out upon the pasture for some time past. They have thriven well this summer, and we shall now begin sending the most forward animals to the butcher off the grass. Low prices have made poor Irish stock a drug in the market. Earnestly do we hope that it will have the desirable effect of driving inferior animals out of the market altogether. Cattle fairs will soon be numbered with things of the past in the eastern counties, so fast is the practice extending of testing the value of all farm animals by the auctioneer's hammer, weekly sales being held at all the principal markets. This is really only an extension of the wise principle of small profits and quick returns. Old ewes upon Clover and mixed dry food are showing improvement. It is not our intention to push them on fast, as we wish to do all we can to impart fertility to the land by folding, and so we do not give the ewes as much corn and cake as they could consume, but prefer to spread out the outlay for food for the benefit of the land. In any case, our expenditure upon artificial manure must be high both now and next spring, and we altogether prefer this outlay to the feeding of live stock, the carting, heaping, turning, and recarting, as well as the spreading, of farmyard manure. If it is possible, as we assert it is, to impart fertility to the soil at a reasonable rate by using artificial manures, does it not appeal to one's common sense that it must effect a very considerable saving to avoid all the costly process of the manufacture and application of farmyard manure? Do not lightly discard our advice, for assuredly it is not lightly given, for we have tried both systems for several years thoroughly, and have long been convinced that manure carts on farms may be dispensed with. The matter is so important that it ought rather to be enlarged upon in a special article than a brief labour note. Procure genuine manures separately and mix them on the farm.

HYBRID WHEAT.

MORE than thirty years may be counted since any known experiments were made in this country in the so called hybridisation of cereals with the view of obtaining new and more valuable varieties. High importance, therefore, attaches to a feat of the present harvest which has been accomplished by Messrs. Carter & Co. of High Holborn. This is the production of veritable novelties in Wheat by crossing some of the finest kinds hitherto resulting from selection. Entirely new sorts have now been developed; and these ought properly to be described as "cross-bred" rather than "hybrid" W heats. Unlike some seedling plants, Wheat does not "inoculate," as farmers name the accidental or insect-governed process by which the character of the produce may be altered in different varieties grown and ripened in close proximity to each other; and perhaps it may be physically impossible that such undesigned cross-fertilisation should occur, though the occasional sporting of new sorts is hardly to be explained by any other agency of variation. Wheat is self-fertilising—that is, in each floret on the ear the pistil is impregnated by pollen from stamens within the same flower; and a provision against cross-fertilisation consists in the fact that the stamens are fully developed and the pollen begins to shed before the florets open, the impregnation of the pistil being accomplished before the flowers appear upon the outside of the ear. Mr. H. Evershed ("Improvement of the Plants of the Farm," in the "Journal of the Royal Agricultural Society") observes that "the clouds of pollen in a Wheat field are, like many other provisions for the security of reproduction, in excess of the customary requirements."

Thus the cross-breeding of cereals involves a delicate operation, demanding the skill and judgment of an expert. The anthers having been removed from a number of Wheat flowers while still in a green state, but near maturity, the pollen of another kind, which it is intended to use as the male parent, is on the following day poured gently on the feathery stigma, and the flowers next to the impregnated ones are destroyed, so as to leave at the time of maturity no doubt as to which grains have been acted upon. Several blooms on the same ear are generally operated upon in this way. It is a fine point, too, to catch the ears just at the right time in relation to temperature. There is a minimum—namely, about 75°—and also a maximum, below or above which the process cannot be performed. Only at a proper temperature of the atmosphere will the flowers open and expose the reproductive parts to the operator. The opening of the glumes is dependent upon a swelling out of the lodicules, which occurs at a particular temperature, and the degree of this swelling corresponds to the angle of opening of the glumes. Further, while artificial impregnation cannot be effected before this spontaneous opening, when fertilisation has once been performed the lodicules shrivel and permit the glumes to close over the pistil. Hence the care in watching, which is requisite for the success of the experiments. The present series of interesting operations are being prosecuted by one of Messrs. Carter's professional experts, under the personal guidance of the manager, Mr. C. H. Sharman, at the experimental grounds, Forest Hill. And, so far, the results have proved as gratifying to these experimenters as they are valuable to the agricultural world.

It appears that the desirability of thus artificially crossing some of the most popular varieties of Wheat was suggested by a competition of the Royal Agricultural Society a few years ago, in which a series of prizes were offered for improved kinds of Wheat, when, after exhaustive trials, the Judges were not unanimous in accepting any of the varieties submitted in competition as really distinct from sorts already cultivated, though two of the W heats were selected as being so far in advance of the others as to justify special recognition by the award of silver medals. In the autumn of 1882 a number of the most valuable samples that could be obtained were sown in plots at Forest Hill. In the summer of 1883 some twenty or more crosses were made. The resulting grain was carefully harvested in 1883, and for the next year's production sown in triple rows—one row of the progeny in each case being grown between the rows of its two parents, this being for the purpose of thorough comparison of any peculiarities of growth and other characteristics. It was observed at a very early stage of

growth that in some cases the hybrid or offspring partook of the creeping and drooping form of the male parent instead of the upright habit of growth of the female. Later it was seen that in some of the W heats the offspring had the smooth chaff of the male instead of the peculiar woolly chaff of the female which has been employed in producing it. These results are repeated in the crops of the present harvest; and we have had opportunities of verifying the observations both at the time of the Wheat coming into ear, again when ripe for gathering, and, further, when threshed or, rather, rubbed out by hand.

In one instance (No. 19 of the experimental triple-rows) the female parent is a short-strawed, velvet-chaffed Wheat, and the male a very large bearded and tall American variety. The offspring is about a foot taller than the female parent, the chaff is more or less smooth, and the thick ears bear minute awns at the apex of the chaff of each grain. These points in serrated order from top to bottom of the tier of sets having been observed to be obnoxious to sparrows, this new variety of Wheat has been distinguished by the name "Bird-proof." In No. 13 the female parent is the well-known early kind Talavera, and the male parent the American Duluth. We are able to confirm Messrs. Carter's observation that, in this case, the offspring ripened and was ready for harvesting fully fourteen days before either parent—a peculiarity observed both last year and in the present season. It may, therefore, be expected that this new variety will prove of especial service for sowing in those countries where the seed time is in spring and earliness is an important consideration. The ears are much finer and the grain appears to be greatly superior as compared with the Duluth, and a fortnight earlier than that variety, which has been up to this time considered the earliest in the United States. As English millers are said to mix certain proportions of red Wheat with imported white for the purpose of giving strength to the flour, Messrs. Carter have sought to blend together the qualities of red and white in one progeny; and as only such varieties as are already known and liked by millers have, in most of the experiments, been the parents employed, it may be anticipated that high milling value will distinguish the offspring W heats. But, at present, the limited quantity obtained has not admitted of any of these hybrids being subjected to the actual milling test.

Among noticed peculiarities of the new W heats, some exhibit in a high degree firm setting of the grain, or non-liability to be shaken out by winds—a desideratum for New Zealand Wheat-growers, who are accustomed to leave the crop until dead ripe before taking off the ears with a "stripper." Another new sort is remarkable for the short, thick, and strong nature of the straw, bidding fair to defy any weight of rain to lodge it, and being especially adapted for poor, cold, or wet soils.

A very important feature of the experiments is the remarkable vigour and productiveness of one and all of the hybrids as compared with the parents. The cultivation has been the same for all, and in each case the same number of grains was planted in each row—the male parent in the first row, the female in the third row, with the progeny occupying the second row between them. The greater number of stems and ears and superior bulk and weight of the hybrids were noticeable to the eye, and in several cases surprising. Yet it will be understood that the outer position in each triplet naturally conferred upon the parents every advantage of range of earth for the roots, and abundance of air and sunlight for the stems, flag, and heads of the growing and ripening corn. It should also be remembered that, while the parent stocks were brought from distant parts and had thus the benefit of change of soil and climate, the offspring grew three years in succession upon the selfsame spot of ground. One example of the vast fecundity of the new W heats ought to be mentioned. One plant was pointed out to us, in No. 9, which bore sixty distinct, very long, and well-filled ears, averaging about fifty grains per ear, or a total of about 3000 grains grown from one seed.

After three years of continued cultivation three of the hybrids are regarded as sufficiently fixed in type and so valuable in distinctive character and properties as to warrant their growth on an extended area next year, with a view of supplying seed corn to the public. These are Hybrid No. 10, a cross between Square-headed White and Hunter's White; No. 13, a cross between Talavera White and Carter's Royal Prize Red; and No. 19, Carter's Fillmeasure crossed with Mammoth White.—(*The Times*.)

REMARKS.

- 6th.—Fine morning, dull after.
7th.—Very dark about 8.15 A.M.; thunder at 8.50 A.M.; wet nearly all day.
8th.—Fine day, but occasionally cloudy; heavy rain in late evening and at night.
9th.—Fine day.
10th.—Fine morning, with some sunshine; cloudy afternoon, with rain and wind increasing to midnight.
11th.—Strong gale, with very heavy rain early, ceasing about 9 A.M.; fine afternoon.
12th.—Wet till 11 A.M., then fair, windy in afternoon and evening.

This week has seen the entire break up of the drought, for rain has fallen nearly every day this month, and on the 10th more fell than in the whole of July and August. Temperature is still a little below the average, and continues to fall with very remarkable uniformity—e.g., the average maximum temperature for the week ending August 15th was 71.3°. The weekly decrease since then has been 1.3°, 1.7°, 1.2°, and 1.0°.—G. J. SYMONS.

EUCCHARIS GRANDIFLORA.

AMONGST choice plants there are few that in beauty and sweetness can surpass the Eucharis. No stove should be without them, for the flowers are always welcome, and with a few dozens of bulbs it is not difficult to maintain a regular supply. They are welcome in summer, but doubly so in winter, at which time they can be produced as readily as when flowers are plentiful everywhere.

The Eucharis is easily propagated by division, and those in possession of a few plants can add to their stock considerably in a very short time. Each strong flowering bulb will produce three or four in a season, which can be taken off and grown on separately or together. When it is necessary to increase the stock we do not see the wisdom of removing the small bulbs from those that have produced them, for they grow more rapidly attached to the parent. They should be grown on together until a number of large bulbs have been produced, when they may be divided and the small ones potted singly.

Potting may be done at almost any season of the year with equal success, but we do not advise the carrying out of this operation during November and December, when the days are very short and growth naturally slow. It should be done annually if the plants are to be retained in health and vigour, not necessarily the whole at the same time, but successively as they go out of flower. It is a mistake to subject the whole to the same treatment at one time, for they must be pushed into active growth afterwards, which would be the means of bringing the whole of them into a flowering condition about the same time. Some cultivators prefer feeding the plants to potting them every year, for fear they should fail to flower satisfactorily, unless they are thoroughly root-bound. Under the system we recommend we have never found any difficulty in flowering these plants. The secret is to encourage vigorous growth and then thoroughly mature it, afterwards subjecting them to a good season of rest. It will be admitted that all plants do better with soil in a sweet healthy condition about their roots, and if this is really the case then it is wrong to keep the Eucharis in the same pots for a number of years. However good the soil may be at the commencement, it becomes sour and exhausted after it has been in the pots for a year.

The Eucharis is not a deep-rooting plant, therefore the pots employed need not be large in proportion to the number of bulbs grown in them. For instance, a 5 or 6-inch pot will be large enough for three or four strong bulbs. Potting is best done directly after the plants have flowered, and the soil we have found most suitable is good fibry loam, one-seventh of cow manure, the same quantity of charcoal, one 6-inch potful of soot to each barrowful of soil, and a liberal dash of coarse sand. Press the soil as firmly as possible into the pots. Afterwards arrange the plants in a close moist atmosphere where a night temperature of 70° can be maintained, with a rise by day of 5°, 10°, or even 15° from sun heat. If the old

soil has been shaken from the roots the foliage must be well syringed until root-action commences. It is much better to syringe frequently than to supply water for some time after potting.

In the temperature indicated root-action will soon commence, and leaf growth should by every means be discouraged until developed and matured, when the plants may be gradually dried at their roots and removed judiciously from the warm to cooler quarters to rest. Nothing is gained by removing them before the foliage is fully developed and growth brought to a complete standstill, for they will not flower unless the bulbs are thoroughly matured. To attempt to bring them into flower when growth is only half completed by plunging them in strong bottom heat is useless, for the growth must be finished before any flowers will be produced. Even when they are rested while the growth is incomplete, the flowers afterwards are small in comparison to those from plants properly grown and matured. No advantage is gained by using bottom heat for Eucharises, for they will not come into flower any earlier or grow any better than in the temperature named.

The season of rest and the treatment the plants then receive are of vital importance to successful cultivation. When growth is completed keep the soil moderately dry before they are removed from a stove temperature, and this must not be done suddenly but gradually, or the roots instead of being healthy after they have been rested will perish. They will stand without injury in any cool house while at rest, provided too much air is not admitted and cold draughts do not strike directly upon them. Very little water will be needed while in this condition; in fact, no more should be given than is sufficient to keep the foliage from flagging. Two or three weeks' rest in a cool house is ample if they are wanted in flower; if not, it may be extended to six weeks. On several occasions I have had plants that have been properly matured before resting push up their flower stems with great strength in a temperature of 50° while endeavouring to keep them back.

Some cultivators contend that a season of rest is unnecessary for Eucharises, and adopt a system of cultivation that keeps them continually growing. This has been thoroughly tested, and for yielding flowers successively should not be practised. For a time the plants will do very well, but no certainty can be placed upon the period they will flower. In all probability a number of them may turn in at a time when they are least wanted. If this was discontinued we should hear less of the disease amongst Eucharises than has been the case lately. Under the non-resting principle the plants exhaust themselves in time, and cannot be induced to grow by any means, and the conclusion arrived at in more instances than one is that some disease has attacked them, and they are conveyed to the rubbish heap. This is no mere conjecture, but has been proved to be the case, and instead of the plants succumbing to some disease they only wanted a good season of rest, and would afterwards have grown again with the same vigour as formerly.

There can be no question that for purposes of decoration and for yielding flowers in succession, plants grown in 5 to 7-inch pots are decidedly the best. Some cultivators grow a number of large specimens only, but this is not the best method to maintain a supply. House room is often limited, and no more can usually be accommodated than are really necessary to supply the flowers demanded; therefore, these plants grown in the pots named have proved the most serviceable. Large plants when well grown, and carrying from twenty to thirty spikes of bloom, are very beautiful. Eucharises do wonderfully well when planted out in a bed prepared for them, and when grown on this principle are admirable for those that require a large quantity of bloom at one time. But when the flowers are wanted in regular succession the planting-out system does not prove the most satisfactory.

Under the system of resting detailed the *Eucharis* can be flowered three times during the year, but in order to accomplish this no time must be lost. Some cultivators can bloom them four times, but this only leaves three months for the plants to make their growth, rest, and come into flower. For one year they may be flowered four times within the twelve months, but this cannot be accomplished the second and succeeding years. While growing the plants require abundance of water at their roots and over their foliage, and even while at rest no attempt should be made to thoroughly dry them, for they are evergreen. Weak stimulants will be required every time water is needed after the plants have exhausted the soil in which they are growing, but feeding only will be needed during the last growth when potted annually.

Thrips and red spider will infest *Eucharises*, but this can be kept down by a free use of the syringe. Mealy bug is their worst enemy, which can be eradicated by sponging with a weak solution of any insecticide recommended for the destruction of bug. These plants do not bear a solution of petroleum and water, for the oil has a tendency to run down after it has been syringed upon the points of their leaves and finally turns them yellow.—WM. BARDNEY.

SOME THOUGHTS AND SUGGESTIONS ON FRUIT AND FRUIT-GROWING.

[A Lecture delivered at Wrexham, Friday, September 11th, 1885, before the North Wales and Border Counties Pomological Society, by Mr. E. J. Baillie, F.L.S.]

(Continued from page 245.)

THE GOOSEBERRY.

THEN there is the Gooseberry crop. This is one of the staple products of fruit cultivation. I was in the south of England in the early days of June, and it was a wonderful sight to see the Gooseberry pickers. Truck after truck is filled at the wayside station, and tons of fruit leave the country centres every day for the London markets. The ripe fruit of the Gooseberry has never been quite so popular, but if well grown, carefully gathered, and packed as dessert fruits ought to be packed, there is no reason why the better varieties should not be brought into more prominent demand. Currants, too, may be grown under almost any conditions, and at very slight expense. As a rule, Gooseberries are planted between the rows of the larger trees, but latterly plantations have been made and acres covered with Gooseberries alone. In this case the bushes are planted, say, 6 feet apart and 6 feet between the rows, requiring about 1200 or 1250 bushes to the acre. If the ground is too moist and heavy the trees have a tendency to carry moss, and in such a condition I have seen soot recommended as a good remedy. There is a fashion in Gooseberries as well as in other things, and, as a rule, a large dark-coloured fruit will have preference in the market. There are enemies in plenty to be taken into account, but we will not go into this aspect of the question.

CURRANTS AND RASPBERRIES.

Of the Currants the Black Currant is probably the safest investment. It is easily propagated, almost always a sure crop, commands a ready sale in the market, and is much safer from the ravages of birds than other kinds. The Raspberry is a fruit at once prolific and profitable, and ought really to find better favour even than it does at present. The rapidity with which it ripens, and the succulent pulpy character of the fruit, makes it difficult to deal with for distant markets, as it suffers considerably in transit. This is a serious drawback from a commercial point of view, but it is a fruit that ought to be abundantly grown for local demand. The plants may be planted in rows 2 feet apart, with from 12 to 18 inches between the plants. They flourish best on dry ground and in a somewhat sheltered situation. As the fruit is most abundantly borne on lateral branches produced near the top of the preceding year's shoots, great care should be taken in regulating the pruning. The number of suckers or canes, as they rise in spring, should be calculated, the old canes being removed in the autumn, and the new canes be shortened and fastened to stakes, as they will be the fruitful plants of the next year, or to save stakes the new canes may be bent into arches and tied together, and this is a good method of training.

THE BILBERRY AND THE BLACKBERRY.

We must not leave the small fruits without naming at least two not generally recognised as cultivated fruits. I allude to the Bilberry and the Blackberry. The Bilberry is just creeping into cultivated ground, with what chance of success and profit it is

perhaps premature to judge, but for clothing hitherto barren mounds and banks it ought to be recognised as worth attention. The Blackberry ought really to be one of the fruits of the future, especially if the illustration of the Wilson Junior Blackberry is at all reliable, and it is said to be taken from a photograph, I observe. In Herefordshire tons of Blackberries are gathered yearly, collectors get them together, and they are sent to the chief centres of population, mainly in the north. The Blackberry is not particular as to soil, but if it is particularly poor it should be well manured and well cleaned. In America the Blackberry is extensively grown, and in field culture the young canes are planted 3 feet apart in the rows, and 8 feet from row to row. The young canes are shortened back to within 5 or 6 feet of the ground. The best time for planting is the month of October. But the Blackberry presents another feature which should commend it. As a decorative plant for old walls or old fences it has few equals, and whilst pleasing the eye for the greater part of the year, as it is always interesting and attractive, from its first early leafage in spring to its rich autumn foliage, which is not impaired by ordinary conditions more or less affecting other ornamental plants, and the leaves do not fall, as a rule, until quite late in the season. The varieties of this fruit best adapted for cultivation are the Wilson Junior, Dorchester, Lawton, and Parsley-leaved.

THE APPLE.

We must now give some attention to the most important of our British fruits, the Apple. It is true that the Apple has not even yet received the attention it deserves, and I think the main reason may be that its value as food is not rightly realised. Upon this aspect of the question we will have some few words, but just now we must consider the Apple as we find it. It is, as you know, the popular fruit in the farmer's orchard, and with the enterprise of the times it is astonishing that such poor specimens, both as to condition of the trees and quality of the fruits, should be allowed to cumber the ground. Varieties that would be most interesting from an antiquarian point of view, the trees covered with moss and lichen, continue year after year to bring their poor return of worthless fruit, and it never seems to strike the owner that it is time to remove the venerable old cripples and have some more in keeping with the wants of the times. Well may America continue to send us her Pippins, seeing we have not yet learned to grow properly for ourselves. In 1882 England paid £783,906 for Apples alone, and the demand is undoubtedly increasing. An interesting point suggests itself here, that of improving the quality of the British Apple. This subject of hybridisation need not be touched to-night, but there is ample room for profitable practical experiment in this direction.

As to the kinds best suited for different localities, the report of the Committee of the National Apple Congress held in the Royal Horticultural Gardens, Chiswick, in October, 1883, gives valuable information. I find Wales was almost unrepresented, but Cheshire exhibited 336 kinds. A few extracts from that report as applied to the county exhibits may not be inappropriate here. Mr. Bancroft of Audlem exhibited a collection of fruits, reported to be somewhat small and deficient in colour, many being unknown, probably of local unnamed sorts. The exhibitor remarked that they had been grown on old standards grafted on stocks raised chiefly from Apple pips. Mr. Bancroft mentioned that to his personal knowledge ten distinct varieties were all called John Apples. There is work evidently for the Pomological Society there. The next exhibit noticed is that of Messrs. F. and A. Dickson & Sons, Chester, who sent an exhibit of 100 varieties. The observations read—"A remarkably fine collection, the examples large and well grown." The exhibitors remarked that the specimens shown had been gathered from bush and pyramid trees, from three to six years old, grafted on the Paradise stock. The situation open, fully exposed to the bleak cutting winds blowing right across from the open plain extending to the Welsh coast. Messrs. James Dickson & Sons exhibited an interesting collection half gathered from trees worked on the Crab, the other from those on the French Paradise. There were other exhibits from the county, including a splendid collection of sixty-seven varieties, exhibited by Mr. Selwood, gardener to His Grace the Duke of Westminster at Eaton. Mr. Selwood remarked that most of the dessert varieties were grown on espaliers, the others on bush trees seven years old. This is a good Apple, distinct, and a crop more or less can generally be depended upon. In the census I find the following varieties were recommended in the order given as dessert Apples best suited to the district—Irish Peach, Blenheim Pippin, Cox's Orange Pippin, Ribston Pippin, Kerry Pippin, Adam's Pearmain, whilst other kinds, including Mr. Gladstone, came in for half the number of votes—this remark has of course no political

significance. In culinary Apples I find Lord Suffield heads the list, followed by Cellini, Dumelow's Seedling, Keswick Codlin, Alfriston, Ecklinville Seedling, Golden Noble, Warner's King, and Winter Hawthornden.

In the poll taken for the whole of Great Britain the varieties are placed in the following order—Dessert Apples: King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Kerry Pippin, Blenheim Pippin, Irish Peach, Devonshire Quarrenden, Sturmer Pippin. Culinary Apples: Lord Suffield, Dumelow's Seedling, Keswick Codlin, Warner's King, Blenheim Pippin, Winter Hawthornden, Cellini, Ecklinville Seedling, Stirling Castle. The Editor remarks that whilst the returns are valuable, as showing the extent of appreciation in which certain varieties are held throughout the country, they cannot be accepted as complete and reliable lists, inasmuch as many excellent varieties of Apples are comparatively unknown in certain localities, and are therefore placed lower down the list than their merits deserve. The most popular Apple was Lord Suffield, having received 101 votes out of a possible 130, King of the Pippins standing next with ninety-eight. The most popular dessert Apple in England is Cox's Orange Pippin, but it is evidently not so well known in or so well suited for the colder climate of Scotland. The list of synonyms given in the report is also most interesting and instructive, but we need not enter upon that subject just now.

Speaking from the experience gained in the immediate district, there are about thirty varieties of Apples which are in demand greatly in excess of the rest. For Lord Suffield the present demand is practically unlimited, and this is closely followed by Blenheim Pippin, Ecklinville, Stirling Castle, Cellini, Maltster, Cox's Pomona, Warner's King, Alfriston, and others; whilst of dessert kinds Cox's Orange Pippin, Irish Peach, King of the Pippins, Worcester Pearmain, and Ribston Pippin hold the lead. Two varieties, Frogmore Prolific and Lane's Prince Albert, are likely to become favourites, as there is a marked increasing demand for them. Trees trained as pyramids are in strong force just now, and with careful management are effective and profitable. Unless orchards are laid down as pasture for grazing, standard trees, with stems not more than $3\frac{1}{2}$ to 4 feet, are preferable to the tall-stemmed trees very commonly planted.

THE PEAR.

The cultivation of the Pear is of much more moment commercially than has been apparently realised. In the older orchards we find Catherine Pears, red and white (called commonly "Cattens"), Hessele, Green Chisel, and Swan Egg, but very few of the better Pears are properly grown and carefully gathered for market. Amongst the better kinds suited to this district are Beurré d'Amanlis, Doyenné d'Été, Jargonelle, Williams' Bon Chrétien, of the early varieties; Beurre Superfin, Glou Morceau, Louise Bonne of Jersey, Marie Louise, Winter Nelis, amongst the mid-season varieties; and Bergamot d'Esperen, Beurre Rance, and Easter Beurre of the later kinds. I have amongst my memoranda a note of a crop of Beurre d'Amanlis grown in the open orchard within a few miles of Chester, having realised last season 3d. per lb. whole sale. In the same orchard the better class Pears are grown both on pyramids and standards of quality equal to any Pears to be found from the southern counties, or even Jersey.

Of Plums very few varieties are found to do satisfactorily as standards in this locality. Victoria, Pershore, and Denbigh Seedling are amongst the best, Victoria being the most reliable of all. I visited a fruit orchard a few days ago where the trees are so laden as to be unable to carry the fruit, and the proprietor informed me that his trees of this variety never fail him. Two years ago the demand for Pershore Plum was so great that I believe the stock of every nurseryman in the kingdom was exhausted. For Damsons we are here in the centre of one of the best of districts, but Cherries are not grown as they are in the southern counties. Two years ago I walked over the home farm of private gentleman in the southern counties, and he showed me a Cherry orchard which he had just planted of 200 acres.

Cherries grew on the trees whilst sheep were pastured on the farm. Shortly afterwards, in a neighbouring county, I found an orchard of Walnuts containing something like 400 trees, the property, too, of a private grower. Besides all these we have Apricots, Peaches, Nectarines, Nuts, Mulberries, Chestnuts, Crabs, Barberries, and other fruits, which we must leave for some other time.

(To be continued.)

EARLY-FLOWERING CHRYSANTHEMUMS.

"We have another dinner party, and there is hardly a white bloom of any kind left. Can you send me a few of those early

white Chrysanthemums you were speaking about? I have no white flowers left at this dull time." So wrote a gardener to me the other day whom I had visited a few weeks before, and where I admired the contents of the numerous stoves and green-houses under his charge, mostly filled with choice Orchids and a thousand other plants. I was informed the family was away, or else I should not have found such a display of bloom at that time of the year. It is when the families return home after their summer tours, and commence giving entertainments and exchange congratulations, that gardeners find their resources so sorely tried, especially at this season. When I first spoke to this gardener on the subject of early Chrysanthemums, I am afraid there was rather a feeling of contempt for what are so generally looked upon as "common." Some remark that that they are dirty looking, others that they seem out of place so early in the season, but I am pleased to find many have recognised their mistake, and have only been too glad to grow a quantity of such varieties as Madame C. Desgrange, Mrs. Cullingford, and La Vierge. These early-flowering Chrysanthemums are the most useful plants that can be grown during the months of September and October, when there is no doubt that gardeners find it difficult to meet the demand for cut flowers. Chrysanthemums go a long way in decorating, and greatly relieve the pressure upon more valuable plants, to say nothing of the long time they remain fresh; a bloom, for instance, of Madame Desgrange can easily be kept upon the plant for three weeks, and then last for ten days in a cut state.

It is fifteen years since I commenced a collection of these early-flowering Chrysanthemums with a view to keep up a display of bloom in the herbaceous borders. They were certainly not very inviting for cutting or for the conservatory, but a great improvement has been effected since that time. Then we only had the small Pompons, and could not boast of a really pure white; now we have many white varieties as pure as can be desired. The first improvements that came into notice were St. Mary and Sœur Melanie, both very free and quite white. The former is a very early bloomer, opening as early as May, and giving three distinct crops of flowers during the season; the latter is an October variety, and has been often noticed in these pages. After these came Madame Jolivart, an excellent variety both for habit and freedom in flowering, but it is only pure white under glass. Quickly following these introductions came Madame C. Desgrange and La Vierge, without doubt the two most valuable white varieties known up to the present time. The former was introduced about eleven years since, but was not much admired until five or six years ago. Even then it was generally described as a loose white flower with yellow or green centre. Whatever it was then, it certainly is a pure white flower now if well cultivated and bloomed under glass or canvas. As a market flower it is more valuable than Elaine, having a lighter and more attractive appearance, but it does not come into competition with Elaine, as it is fully two months earlier. Flowers of Madame Desgrange, too, are far superior to white Asters, and give four to six times the number of blooms for the same space and labour. La Vierge may be described as a much-improved Sœur Melanie, only rather earlier. It is a medium-sized reflexed flower, opening its blooms early in October, thus connecting the link between Madame Desgrange and the earliest of the late varieties, such as Lady Selborne and Elaine. With such very late varieties as Princess Teck, Miss Maréchaux, Mrs. Carey, and others, we now have pure white Chrysanthemums quite eight months out of twelve. Other fine white early Chrysanthemums are Mrs. Cullingford, a very fine white hybrid Pompon, a variety raised by Mr. Alfred Salter. Equally as fine as a garden flower or for the conservatory are White St. Crouts, Virginia, and La Niège, the latter a late October variety.

Turning to the coloured varieties, I need only say that as great improvements have been effected in these as in the whites. I will mention a few of the best—Lyon, a very fine purple flower, one of the very best; Anastasio, light rosy purple; Flora, very fine yellow, replacing Precocite; Filberta, fine yellow; G. Wermig, the new yellow sport from Madame Desgrange; Frederick Marronet, a bronze Pompon; Mons. Pynaert Van Geert, a beautiful Japanese, yellow striped bright red; Nanum, blush white; La Petite Marie, white with yellow tint, exceedingly dwarf; Isidore Feral, a Japanese flower, rosy lilac and golden centre, very fine; and Alexandre Dufour, a very fine medium-sized Japanese, bright purple, late October variety. The whole of the varieties mentioned in these notes, except Nanum, are introductions of the past twelve years. They do not comprise all the best sorts, but outside the enthusiast, the whole of the previous introductions might well be swept away. There are several new varieties of the present season very promising, but it would be well to reserve mention of them till further trial. There is one,

however, which might be noticed, as it will most surely become one of the most popular of all—Blushing Bride, a splendid new acquisition, and the first in the early section at all approaching to the incurved form. The flower is something in the way of Miss Hope in the late Chrysanthemums. I have only been able to get weak plants of it this season, but they have been one mass of flower. I enclose specimen spray, perhaps the Editor will give an opinion upon it. I also have pleasure in adding blooms of a few other varieties, notably Madame C. Desgrange and its golden sport, which I regard as a most valuable acquisition, and congratulate Mr. Wermig upon fixing such a sport.

In conclusion, I would like to point out that the varieties denoted in this article as early Chrysanthemums are all really free flowering summer and early autumn varieties. I have seen varieties occasionally mentioned that have not the least title to being classed in this family, being merely the result of propagation from stem cuttings, which may be said to have the buds in them before struck, but they only produce the one bloom as a rule, and then either die or grow on till their natural time. Most of the new introductions from France bloom prematurely the first season unless the buds are pinched out. I find they are chiefly struck from stem cuttings, and hence the reason.—N. DAVIS, *Chrysanthemum Nurseries, Camberwell*.

[Accompanying this communication was a beautiful collection of flowers, which fully bears out all that Mr. Davis has said in their favour. They are most useful plants, and are extremely welcome at this season either in borders or in pots for the conservatory, while their abundant flowers form a welcome addition to the supply. The variety Blushing Bride is a charming one, the flowers $2\frac{1}{2}$ inches in diameter, the florets slightly cupped, and the colour a delicate pretty rosy purple tint, fading to nearly white in the centre. It also appears very floriferous. Salter's Early Blush, also a pleasing variety, has flatter florets of a more uniform lighter pink; Anastasio, small flower, but very free, though of sturdy compact habit; Lyon, an extremely hardy useful purple variety; Surprise is a new early Pompon with small neat pink flowers; Frederick Pele, an old but useful rich crimson-coloured variety; Flora, rich yellow, very free and valuable for bedding; La Petite Marie, a very dwarf bedding variety, the whole plant not exceeding 10 inches in height, with small neat white or yellow tinted flowers; Mrs. Cullingford and White Crouts are meritorious white varieties, but the specimens of Madame C. Desgranges sent are superb, pure and substantial, as well as the light yellow sport, G. Wermig, which is a fine companion for it. Bouquet National, an early rosy purple Japanese, and M. Pynaert Van Geert, bronzy yellow, of similar character, are also two charming varieties.]

JUDGING GRAPES.

I wish to add a supplementary testimony to Mr. Iggulden's sensible remarks on the above subject. Want of time must be my apology for not doing so sooner, as I quite agree with him regarding the present system of judging Grapes at the various fruit and flower shows I have had the privilege of visiting this season. At one held in this neighbourhood on the 3rd inst., forty-two bunches of Grapes were staged, and not a single berry was taken off them by the Judges—appearance alone carried the day. In the class for four varieties, one bunch of each, a good even collection in fair condition was set up, consisting of Mill Hill Hamburg, Madresfield Court, Muscat Hamburg, and Muscat of Alexandria, against which were staged Cooper's Black, Alicante, Gros Colman, and Muscat of Alexandria, for which the first prize was awarded. In the class for two bunches black, any variety, Cooper's Black was again awarded the premier prize against two well-finished bunches of Muscat Hamburg, one of the best flavoured Grapes in cultivation, and not the easiest to finish either, whilst Cooper's Black, although a showy Grape with a splendid bloom, is, nevertheless, one easily brought to perfection, yet is not fit to send to table for at least two months after being apparently ripe. Alicante and Gros Colman are not September Grapes, and one might ask, Are Grapes intended for desert or are they to be sent to a gentleman's table like a bouquet of flowers, only to be admired? Let a dish of Black Hamburg, Madresfield Court, Muscat Hamburg be set on the dinner table against the three varieties already referred to, and we should soon see which dish would be cleared first. I hope this matter will be taken up by competent writers, so that honest competition shall have its just reward, and when the time comes for judging Grapes at our local shows, men will be appointed to adjudicate who will not give all the preference to appearance, but taste and see which is best.

Just a word on that noble Grape, Madresfield Court. I have frequently read that its great defect in the hands of some cultivators is splitting just as it approaches maturity, some assigning one cause and some another, such as keeping the roots too damp, not allowing the laterals to extend, &c. Now, I have grown it for the last eight or nine years, planted in an outside border, where, of course, it gets a due share of rainfall, and in dry weather as much from the watering can as any other variety, with the laterals removed the same as others, and I have never had cause to find fault with it for splitting when watering and

ventilating were duly performed. I would, therefore, advise anyone troubled with berries splitting to crop fairly, thin the bunches liberally, keeping a moderately dry atmosphere with plenty of ventilation while colouring, and we shall soon hear less complaints about one of the finest Grapes in cultivation.—R. R., *Belfast*.

If Mr. Iggulden's ideas on judging Grapes are to be held as correct, and to be acted upon, then all our fine late Grapes should never be shown at any autumn exhibition. This would not be subject of regret if there were more shows held in winter and early spring, when all such varieties as Gros Colman, Alicante, Lady Downe's, &c., would be at their best; but until there are more shows at that time of year, it surely may be permissible to exhibit such kinds as aforementioned in autumn rather than not show them at all.

If Mr. Iggulden's advice be acted upon, our shows will be robbed of many fine-looking samples of late Grapes, which, although not arrived at their perfection as regards edible qualities, can be shown in such a style as proclaims to all who know anything about them that time alone is needed to see them at their best every way. Let special shows be held throughout the country where late Grapes can be shown in season, and then there would be no excuse for exhibiting them in early autumn. There are many shows held in March and April, but that is rather late to have the bulk of late Grapes seen to advantage. Let there be exhibitions in, say, February, and a good display could be made. Of course, Lady Downe's attains its best quality in March, but, taking one kind with another, February would be a better time to see late Grapes shown in edible condition.

I only support "Judges in their preference for colour rather than ripeness" when size of bunch and berry and perfection of bloom are combined with it; when these are found in a late Grape—which only requires a little more time to make it fit for table—I fail to see why it should be passed over simply because the show is held at a time that suits some other varieties better. Unless late Grapes be entirely excluded from autumn prize lists there appears no other course open for judges than to make allowance for want of edible quality in late varieties when other essential points of good quality are conspicuously displayed.

Mr. Iggulden thinks I miss a point when he refers to the sacrificing of late Grapes at autumn shows. There are many Grapes shown, both late and early kinds, which never appear, or are intended to appear, at the employer's table. Where well served, most reasonable employers do not grudge the cutting of a few bunches not quite fit for the dessert table, when they are made to understand that no other convenient opportunity of exhibiting them can be had. I speak of those gardeners who make showing only secondary to their employers' interests, and grow a crop, not a special few. In the latter case a long-suffering employer could hardly be expected to allow the "select few" bunches to be cut at a time, when, for after use at the dinner table, they are comparatively quite unfit. I would never advocate the placing of "really good Madresfield Court" third to "two lots of only fairly good Alicantes." I only advocate placing "extra well grown Alicante" before Madresfield Court when the latter is not shown in its best form. Mr. Iggulden admits that he would do this himself. What comes of his theory about Alicante not being admissible at all at shows held in August or September, when he makes this admission regarding "extra well grown Alicante?"

There is no other way out of the difficulty than either banning late Grapes altogether from early autumn shows, or else allowing the judges to weigh all other points and make allowance for the late kinds being wanting in edible qualities through want of time. "A Young Exhibitor" asks, Why should Madresfield Court "be passed for Grapes less fine in berry, less in weight, less noble in appearance, and lacking in flavour?" He may well ask, "Why?" So would all Grape-growers, I think. Any judge who would pass Madresfield Court, superior to any other kind in all the points mentioned, would deserve to be severely taken to account. Surely such cases are rarely to be met with?—S.

THE PRIMULAS.

In view of the Primrose Congress to be held at South Kensington early next year by the Horticultural Society I have thought it desirable that a list should be published of the Primulas known to be in cultivation, both European and Asiatic, &c., and which may in a measure tend to further the ends of the Congress by enabling growers or intending exhibitors of these beautiful alpine flowers to judge of the numbers in cultivation, and also to interest themselves in getting their plants named correctly. Many are of opinion that such a Congress is undesirable from the fact that very little, if any, confusion exists among them, and that other plants are more in need of comparison. The latter is by far the best argument, but as Primulas are extremely popular garden flowers the Congress will be as welcome next year to those specially interested as it would be later; besides, it is much easier to deal with slight confusion than to unravel what would be very great confusion a dozen years hence, especially when we note the rate at which these plants are imported from the Continent and plentiful but similar forms made to supply the place of the rarer ones. Mr. Baker of Kew and Mr. Lynch of Cambridge have been deputed to draw up a list, but as that will simply be a classification of the European species without cultural details it will in no way interfere with my present plan. In the paper referred to attention will be given chiefly to the type species, and which will form a foundation

on which *Primula* reformers will have to work. Only the most distinct varieties will be included under their respective heads.

My purpose will be to follow Mr. Stein's plan, inasmuch as I shall give both natural and artificial hybrids a separate place, reserving space at the end for a classified key to the whole. Stein, Gusmus, Obrist, Kerner, and others have given considerable attention to the cultivation and determination of natural hybrids by testing artificially and proving exclusively the types or varieties employed by Nature in the production of any new hybrid, and to them we are also indebted for the introduction of many of the fine kinds at present beautifying our rockeries and gardens. The "Genera Plantarum" gives between seventy and eighty distinct species, but many new ones have lately been added to this, and a hundred will now be near the total. Of course this number necessitates many of the plants we consider as species being reduced to varieties; and although it be true that between some of our supposed species links in the shape of varieties may be traced to fill up the whole chain in a botanical sense, many of the intermediate forms are distinct garden plants, and in the latter sense may be said to be as far apart from the two extremes as they are from each other, and quite worthy of distinct names.

The majority of the *Primulas* grow freely in the open rockery. A few, however, will hardly give entire satisfaction unless grown in pots, a system entailing too much trouble to a great number of hardy-plant enthusiasts; but the same difficulty is experienced on the Continent, the home of the European Primroses, and in addition to those planted on the rockery a collection is kept in pots simply stood on beds of sand and protected only from heavy rains in winter. The latter give more satisfaction than those planted out, and this applies not only to *Primulas* but to all true alpine plants; and although I do not advocate growing our collections in pots, it is well to bear in mind that it can be tried for all plants that are difficult to flower or even to grow on the rockery in the open air.

In cultivating *Primulas*, whether in pots or on the rockery, a supply of small stones is essential. I use limestone and hard granite, and a good general rule we adopt, with fair success, is to wedge all the hard-leaved ones, such as *spectabilis*, *calycina*, &c., in the granite, and the soft-leaved species, such as *viscosa*, *ciliata*, &c., in the limestone. In potting or planting the pieces of stone should come as far up the "collar" as possible, adding others as the plants grow, and when roots will be found to have formed above the stones. They must have free drainage, and the pots must be plunged to insure a cool bottom for the roots. Plenty of water is required during the growing and flowering seasons. When planted out a position should be chosen on slopes, or in such a way that no damp will lodge near the neck. Most of them are easily increased, the types by seed and the others by division or by taking off the little side shoots that will have been produced during the growing season.

P. marginata strikes readily from cuttings, as also does *P. auriculata* and others, simply preparing the side shoots, and putting them in pots as practised in the case of other hardwooded plants.

To avoid confusion in the authors of names, as they will be abbreviated, it seems necessary to give a list of them in full, with their abbreviations, particularising only those writers who have been specially engaged in the determination of hybrids, &c.

Others that will be used in the course of the series will be written in full. Those interested in the work of determining hybrid *Primulas*, and who give special attention to it, are Dr. A. J. Kerner, Professor of Botany in the University of Vienna; he has long been interested in alpine plants, and particularly *Primula*. He recently published a paper in German (which has been translated by Mr. Bennett) on the origin of the garden *Auricula*; he is still engaged in the work, and is considered a reliable authority. M. B. Stein, who cultivates crosses and determines the plants, is Inspector of the Botanic Gardens, Breslau, an enthusiast in hardy plants, as indeed are most of the inspectors of continental public gardens; he also has published in German a good list of the *Primulas* in cultivation in Europe with their synonyms, which should be in the hands of all

intending exhibitors. M. Rupert Hunter of Sterzing is a botanical collector, chiefly in the Tyrol; he, however, works most with dried collections, supplying herbariums, with rare specimens.

Obrist and Gusmus are both extensive collectors, the former being also an enthusiastic cultivator; the latter collects living plants, supplying the trade, &c.

P. ALPINA, *Schleich.*—A hybrid between *P. superauricula* and *P. viscosa*, *Stein* (Syns., *P. rhætica*, *Koch*, and *intermedia* of gardens). It is a very handsome plant, found at elevations of from 6500 up to nearly a thousand feet in the Grisons. It is a quick grower, and does well with us on a rocky slope or wedged between hard stones in pots. It rarely exceeds 3 or 4 inches in height; the flowers nearly, or often more, than an inch in diameter, are of a very brilliant violet purple, and extremely handsome. It partakes more of the character of *P. Auricula* than it does of *viscosa*, and which predominance the whole plant shows clearly at a glance. The leaves are much smaller and narrower than those of the *P. Auricula*, smooth, slightly glazed, and with an entire absence of meal dust so conspicuous in that species; they are covered on both sides as well as the margins with a short minute pubescence, are obovate in shape, but again broadening towards the base, and where they clasp the stem the upper half is irregularly and sparingly notched. It flowers a little later than *P. Auricula*.

P. ALLIONII, *Loisl.*—This is a gem among *Primulas*, and next to the common *P. minima* one of the prettiest of the dwarf section. It prefers soft porous limestone to all other kinds, and in preparing soil, a third of sphagnum should be finely chopped and mixed with it, together with broken mussel shells. A south-east exposure seems to suit it best; and as it is inclined to grow saucer-shaped, it should have a semi-perpendicular position, as a double safeguard against moisture remaining stagnant among the leaves or near the collar. It is a slow grower, and so compact do the crowns keep together, that the individual plants look like so many dark green balls stuck in

Fig. 43.—*Primula Allionii*, *Loisl.* [From Reichenbach's "Flora Germanica."]

the rock. It is, perhaps, the rarest of the old species, which is rather surprising, from the fact of its being so easy to cultivate. The flower scapes carry generally one, but sometimes two and three large rosy purple flowers, as in *P. minima*, covering the entire plant. They are about an inch in diameter, with slightly indented petals; the calyx is nearly globose in outline; the sepals are ovate and blunt, quite covered with a fine glandular or clammy pubescence, as well as the leaves. The leaves are obovate, gradually tapering to a short petiole, and slightly crenated. Native of Piedmont. Flowers April and May. Syn., *glutinosa*, *All.* The plant is shown of its natural size in fig. 43.

P. ALTAICA, *Lehm.*—An acaulescent plant nearly allied to the common Primrose of our meadows, indeed almost too near to be separated as a species, but as the characters are constant it may save confusion if kept distinct. It was introduced to our gardens by Mr. Darbishire of Rivington, who is said to have found it growing on grassy land in the neighbourhood of the Black Sea. Its only fault seems to be its tendency to flower too early and before our severe weather is past, the flowers being completely destroyed in exposed situations. When planted out as an edging in the conservatory it is very beautiful, cheering the dull days of winter with its rich purple flowers and distinct bright yellow eyes. They are borne singly on stalks direct from the crown, and from the centre of the leaves, as in our native one. The leaves seem to be more robust, and of a slightly different veining. Syn., *P. undulata*, *Fischer*, *P. nivalis*, *Turtshch*, *P. longiscapa*, *Led.*, and figured in "Pact. Mag.," 16, 194.

P. ARCTOTIS, *A. Kerner.*—A hybrid between *P. subauricula* and *P. hirsuta*. The leaves are broadly ovate, deeply serrated to where they taper at the base, densely covered with tiny glandular hairs on both sides, forming rosettes as in *auricula*, but with the shrubby-like habit of *P. marginata*. It grows well wedged between pieces of granite on an east exposure; and is to all appearance a shy flowerer. I have never seen it in flower.

P. AUCHERI, Jaub and Spach.—A very rare and little known *Primula*. The flowers are produced in whorls, as in our well-known *P. verticillata*, about a dozen in each whorl, lovely purple, and surrounded by leaf-like bracts with sharp serratures; the sepals are narrow and pointed, much shorter than the long slender tube; leaves lanceolate, gradually tapering to the petiole, reticulated with notched margins, and alternate only on the shrubby stems. It flowers in May.

P. AURICULA, L.—The Bear's Ear or Canary-bird Primrose—the latter name being very characteristic of the typical plant—is, next to our own native *Primrose*, perhaps the best known in gardens of all European kinds. *P. Auricula* has until lately been considered the sole parent of all the curious and beautiful Show, Fancy, and Alpine Auriculas grown in gardens at the present day; and judging from general appearances, the long-held impression carries considerable weight with it, even after Prof. Kerner's paper. Prof. Kerner, after a long and careful study of the subject, attributes the origin of the garden Auricula to *P. pubescens* of Jacq., a species the type of which has hitherto been very little known in gardens, and certainly has never been in general cultivation. It was first gathered by Clusius of old in the Tyrol, and at that time introduced, little or nothing being heard of it again until found by Prof. Kerner in 1867 on the Innsbruck Hills. For such a conclusion Kerner must have had strong reasons, but we are rather inclined to the belief, all things considered, that *P. Auricula* has played a very prominent part in the history of garden Auriculas if not in their origin. Mr. Baker says, "It seems to me quite impossible to take a walk through any Auricula show, with this *Primula pubescens* in memory, without feeling that Prof. Kerner's paper is very far from having exhausted the whole subject. My own view is that a very large proportion of our garden Auriculas are nearer to *P. Auricula* than they are to *P. pubescens*, and that the garden Auricula of the present day is the product of a complicated series of intercrossings, of which *P. Auricula* has been the main groundwork, and into which *P. Balbisii*, *P. venusta*, and *P. pubescens* have also entered." Let us bear in mind that *P. venusta* is *P. Auricula* × *P. carniolica*. *P. Balbisii* is nothing more than a variety of *P. Auricula*; and *P. pubescens*, according to Kerner's own showing, is *superauricula* × *hirsuta*, and it will not be hard to understand the justice of Mr. Baker's remarks. Prof. Kerner, however, proves one thing conclusively—*i.e.*, the tale that the Auricula of the Alps changes its colour under cultivation; but when he says that the dusty English Auricula is the produce of *P. pubescens* fertilised with *P. Palinuri*, the latter reminding one more of a Cabbage than a Primrose, we confess to be drawn back to our starting point, *P. Auricula*. This subject will no doubt be thoroughly threshed out at the Conference, where every facility will be given for a fair judgment on seeing the various races of Auriculas, both mealy and Alpine, staged side by side with those said to have played a prominent part in their origin. As far back as 1629 Parkinson enumerates no less than twenty varieties of Auricula, and for want of better names were known as Great White, Lesser White, and so on, a violent contrast to the high state of perfection of these days. Auriculas at the present time are more popular, and are held in higher esteem by the public than they have been at any other time in their history, and deservedly so, for no plant shows the skill of the cultivator and the importance of careful selection more strikingly than the Auricula. Auriculas are divided into two great groups, with mealy and unmealed centres, and termed respectively Show and Alpine varieties.

P. Auricula, the type according to Obrist, has no smell whatever in a wild state, although its fragrance is one of its chief attractions under cultivation. It varies according to the locality in which it is found growing, sometimes being found with the leaves quite green or only slightly mealy, and at other places they are completely covered with a fine powder. The leaves are fleshy, succulent, nearly obovate in outline, with almost entire or deeply serrated margins, generally about 2 inches long; the flowers are produced on stalks from 3 to 6 inches long, in umbels, generally from six to twelve-flowered, but Stein says often more than fifty; they vary in colour from light to dark golden yellow. It is extremely easy to grow, and will do almost as well in the ordinary garden border as in the rockery, providing the soil is well drained and not too heavy (this will apply to all the Alpine section). We succeed best with it, however, on a stony bank having a west exposure, and where it receives plenty of water all through the summer months. The Alpine varieties do exceedingly well on the rockery, and a pretty show they make in the early spring with their ever-welcome flowers, ranging in colour from red through all the shades of purple, violet, yellow, &c., some being self-coloured, others having variously tinted throats or eyes. They are natives of the Alps of Central Europe, from Dauphiné to Transylvania.—D.

(To be continued.)

WHINHAM'S INDUSTRY GOOSEBERRY.

On pages 252 and 253 of last week's Journal you gave a description and plate of the above, but not a correct account of its origin. It was

raised at Morpeth in Northumberland by the late Mr. Robert Whinham, nurseryman, &c., about forty-two years ago. Mr. Whinham left Morpeth for America about fifty-five years ago, but not being successful he returned to Norfolk ten years later, his family keeping the nurseries on during his absence. He succeeded in raising the above about 1843, and being personally acquainted with him I saw it growing and bearing about 1847. He sent it out, but only in a small way, about 1850 at 1s. each, but it made little progress for some years, though now there is about 90 per cent. of it growing in this neighbourhood. I myself have four acres of it, about 4000 bushes. It is not uncommon to pull a net-basket, 56 lbs., off a bush eight years old; in fact, I have pulled 84 lbs. off a bush. Mr. Whinham died at Morpeth about twenty-five years ago at eighty years of age, having, with the exception of the ten years he was in America, lived all his life at Morpeth, so it is impossible it could have been raised in Lancashire. It is of a very robust constitution, making a bush in half the time of almost any other variety of Gooseberry. I have some two years old now that have made shoots 30 inches long this season, dry as it has been.—G. C.

WE learn that the OFFICIAL REPORT OF THE COMMITTEE OF THE ORCHID CONFERENCE, held at the Royal Horticultural Society's Gardens at South Kensington on the 12th and 13th of May, 1885, will be issued in October next. This report in book form of octavo size, and containing about 150 pages, will be distributed to all Fellows of the Society as a number of the Journal, and it will embrace:—1, A report of the proceedings at the Conference, including a paper read by Mr. H. J. Veitch, F.L.S., on the Hybridisation of Orchids, with illustrations, and a paper by Mr. James O'Brien on the cultivation of Orchids. 2, Botanical and horticultural reports by Henry N. Ridley, Esq., B.A., F.L.S., Natural History Museum, South Kensington, and F. W. Burbidge, Esq., F.L.S., Trinity College Gardens, Dublin. 3, An alphabetical list of the genera of Orchids. 4, A catalogue of exhibitors and exhibits.

— FUNGUS ON SWEET WILLIAMS.—This season we have had a number of plants of Sweet Williams infested with a dark fungus which occurs in abundant patches on the foliage. Dr. M. C. Cooke determines this to be *Puccinia Dianthi*, a not uncommon fungus, but peculiar in this case, as it only attacked the plants from one packet of seed, the other plants in the garden and quite near them having escaped injury.

— A NEW edition of Mr. A. Graham's GUIDE TO HAMPTON COURT has just been issued, and contains in the sixty pages much interesting and useful information respecting the Palace and Gardens. The first part is devoted to general particulars and history of the Palace, the second dealing with the horticultural features. In the latter a list of bedding plants is given, with hints upon their culture and propagation, a number of tasteful diagrams of beds with methods of planting accompanying this portion, a descriptive list of the beds at Hampton Court for the present season being also given. The Guide can be obtained direct from Mr. Graham, post free one shilling.

— MR. J. W. MILLS, Minterne, sends the following note on POTATO PRODUCE:—Having planted sixteen eyes I took from two Potatoes weighing half a pound (The Flounder), the produce from the above was 75 lbs., all sound and good when taken up. The largest Potato weighed 2 lbs., six of the largest 9 lbs. They were laid exposed to the air, and are now turned green. Some few of them have taken the disease since being lifted.

— "W. D." considers that "PEARS IN POTS should, in our uncertain climate, have more general attention, and this is apparent when looking at 300 well grown Pears in pots at Harefield Grove just now. Buerré Clairgeau is very fine, and Buerré de l'Assomption, Doyenné du Comice, Pitmaston Duchesse d'Angoulême, Louise Bonne de Jersey, Marie Louise d'Uccle, Buerré d'Amanlis, and Buerré Superfin are fruiting freely with fine clean fruits, and are varieties for amateurs to start with."

— "T. H." sends us an extremely handsome bloom of CHRYSANTHEMUM MADAME C. DESGRANGES, which in size, substance, and purity is equally as fine as Elaine. The bloom sent was 5½ inches in diameter with broad, pure white florets, and Mr. N. Davis has also sent us some nearly as large.

— MR. J. GODDARD of Fulham has recently on several occasions exhibited at Kensington samples of a PATENT CLIP OR HOLDER that will prove useful in many ways to amateurs. In the words of the patentee, "It is designed to hold together two or more pieces of glass, slates, or other suitable material to form a protection from sun, wind, &c." The clip is simple and ingenious in construction, consisting of a screw which passes through a triangular pad that can be removed when desired, and by means of one or two of these clips two sheets of glass can be firmly secured in position to form a small span handlight, or four will hold five sheets of glass as a flat-topped handlight. It will be found useful in many ways, as the screws can be very readily removed.

— GARDENING APPOINTMENT.—Mr. John Cameron, outside foreman at Melville Castle, Lasswade, has been appointed gardener to H. Fryder, Esq., Westbrook Hay, Hemel Hempstead.

— THE monthly meeting of the BELGIAN HORTICULTURISTS was held in Ghent on the 14th inst., when the following members of the Jury were present—MM. Fr. Desbois, V. Cuvelier, Edm. Vervae, Ch. Spae, Em. de Cock, and Charles Van Geert of Antwerp, M. Auguste Van Geert, senior, presiding, and M. Ad. Rosseel being Secretary. Certificates of merit were awarded for the following plants—*Cypripedium* species from M. A. Van Geert, senior; *Tradescantia albo-vittata* from M. E. Pynaert Van Geert, *Dracæna australis variegata* from MM. Desbois et Cie.; *Cypripedium Petri*, *Tonsum*, *cœnanthum superbum*, *albo-purpureum*, *tesselatum porphyreum*, and *selligerum majus* from M. Jules Van Heye-Leyssen; *O. ontoglossum facetum* from MM. Vervae et Cie., *Rhus Cotinus pendula* from MM. Dervae frères, Wetteren; *Pavonia intermedia* and *Abutilon chrysostephanus* from MM. Desbois et Cie., *Gymnotheca Rad-diana crenata*, *Piper ornatum*, and *Arenga Kasarinei* from M. Aug. Van Geert, and double Tuberous Begonias from M. Louis Van Houtte. Honourable mention was accorded for *Rondeletia speciosa* from M. Ch. Spae, *O. ontoglossum grande* from M. James Bray, *Anthurium Chantrieri* from M. Desmet-Duvivier, *Dracæna Madame Ad. D'Haene* and *Adiantum Legrandi* from M. Ad. D'Haene, *Bollea* species from MM. Vervae et Cie., *Pescatorea* species from M. Desmet-Duvivier, and single Tuberous Begonias from M. Louis Van Houtte.

— IN the majority of CATALOGUES issued by nurserymen and seedsmen at the present time the literary merit is considerable, and the accuracy of the names is very commendable. We have, however, a curious example of an opposite character before us, which indicates some singularly erratic notions respecting plant nomenclature. *Iris Geamania* can be recognised without any difficulty as *Iris germanica*, but *Iris Susannah* requires a moment's reflection before *I. susiana* is suggested, and we might equally ponder over *Iris Tuber Roses* for *I. tuberosa*. *Scilla Peacocks*, *Bella Donna mina*, and *Spierie Japonica* are slight wanderings which may be forgiven, but the genus which has evidently most severely taxed the powers of the compiler is the *Fritillaria*. This we first find as *Frittalara*, which narrowly escaped being correct; a little further we come to *Frittelaria Meligus*, which apparently did not give perfect satisfaction, for it is ultimately developed into *Frittelaria*. This is slightly confusing, and it is hoped that it will be found convenient in the next issue to adopt a uniform mode of spelling such names.

— REFERRING to *OMPHALODES LUCILLÆ*, "J." writes—"I am pleased that "C. R." has called attention to the protector for this choice alpine; it had slipped my memory at the moment when writing, and does not differ materially from that described by your correspondent. The first of these I ever saw in use was in Mr. Whitehead's garden at Bickley, and was composed of a small band of perforated zinc gauze, so as to form a circle, the ends meeting as nearly as possible; a slightly larger hole was made to allow a stout piece of copper wire to pass through and round the interior, thus causing a continuous electric current sufficiently efficacious to ward off the attacks of slugs and similar pests. This simple though effectual invention I termed—for it was then unnamed, I believe—"Electric Alpine Plant Protector," and apart from its uses for placing round alpine gems to protect them, it may be employed round the young stem growths of *Lapageria alba* and any other similar subjects which slugs attack in their younger stages of growth. I did not employ the protector for my first plants of this lovely Navelwort, but which were protected with a square handlight, and planted in equal parts of peat and sandy loam; and though it may not be strictly opposed to limestone, this is by no means essential in its successful cultivation."

— THE BOTANICAL MAGAZINE for August and September con-

tains plates representing the following plants:—*Allium giganteum*, a Central Asian Onion of large size, with dense globular heads of purple flowers. It was collected by O'Donovan in the Merv Expedition. *Sisyrinchium filifolium*, an interesting plant from the Falkland Islands, where it grows in "the bleakest spots of the globe." The flowers are white streaked with rose, and it is known as the "Pale Maiden." *Delphinium cashmerianum* var. *Walkeri* has large violet-purple-tinted flowers, and roundish lobed leaves. *Eucharis Mastersi*, a recently introduced species, intermediate between *E. grandiflora* and *E. Sanderi*; a small free-flowering variety of the latter is shown in the same plate, and named *multiflora*. *Alpinia pumila*, a curious plant with red-striped flowers in clusters, not unlike some of the *Pleiones* at a glance. It is a native of Eastern China, and is believed to be either a new genus or a distinct section of *Alpinia*. *Anthurium Glaziovii*, a new Brazilian Aroid, with fine dark green leaves and a large purple spadix. *Pentstemon Menziesi* var. *Scouleri*, a larger free-flowering form of the type, the leaves narrow and flowers purple. *Arctotis aureola* and *A. revoluta*, two showy species, the former bright orange red, the latter smaller and paler in colour. *A. aureola* is a very handsome old garden plant that has been lost for some time, but was obtained by Mr. R. I. Lynch as *A. speciosa*. *Didyosperma nanum* is an Assam Palm of the *Areca* tribe, with pinnate leaves in bold divisions. A good plate of *Primula Auricula* is also given showing the character of the typical plant.

CULTIVATING EDIBLE FUNGI.

AFTER the genial rain we have had, our meadows and woodlands must be abounding in delicious Mushrooms of many varieties—delicious to the taste as well as delightful to the eye. Now I want to ask why, in these days of "Mushrooms for the Million," if we wish to buy Mushrooms or spawn, we are restricted to the Meadow Mushroom, *Agaricus campestris*, or its inferior, the Horse Mushroom, with its black or subfist gills. Has it ever been proved by experiment that it is unprofitable or too expensive to produce spawn for growing other varieties, as *Lactarius deliciosus*, *Boletus edulis*, *Agaricus procusus*, *Chantarelles*, or any other of the thirty well-known edible fungi described by Mrs. Hussey and others, with full directions how to cook them? Has any capitalist ever ruined himself in the endeavour to cultivate artificially "Jews ears?" The savour-to-gravy, soup-and-sauce-giving Morell, said to have been sold in Covent Garden Market for 16s. per pound. Herefordshire, I believe, is the mycologists' paradise. Could not some of the Mushroom excursionists of that favoured region do us the kindness to undertake a few experiments in the way of producing spawn for the market, so that the fried Mushroom, so dainty at breakfast, might be as varied as the fried fish? And might not horticultural societies at their autumn shows for vegetables include a prize or prizes for the best dish of Mushrooms artificially grown or cultivated in the open ground, in the home kitchen garden not less than six varieties? Will some correspondent give an answer to these questions?—the Q. E. D. to the perplexed—X.

GRAND DUKE AND SELF-HELP PLUM.

MR. RIVERS' letter respecting my exhibit of this Plum at the meeting of the Royal Horticultural Society's Fruit Committee on the 8th inst., for comparison with my seedling Self-help, is most unfair and uncharitable towards myself. He does not deny, although he raises a doubt, that the comparing specimens were of Grand Duke, but he charges me with having intentionally picked inferior fruit for the purpose, and speaks of me as if I were a contending exhibitor at an ordinary show of the Horticultural Society. Surely there should be no contention at the Fruit Committee meetings, of which Committee Mr. Rivers is a member, and appears to have been present at the meeting on the 8th inst. I had not anticipated contention; I sent the Plums in good faith, fairly gathered, and for the dry season and position of proportionate size and ripeness, certainly with no intention of disparaging Mr. Rivers' productions or of incurring his hostility. I selected Grand Duke for comparison with Self-help as being the variety which approximated mostly to it in colour, shape, size, fertility, and general appearance, but differing from it a good deal in the period of ripening. Self-help in a crowded and shaded position being fully ripe and dropping, Grand Duke having in a full south exposure only a few fruits quite coloured, and these were selected. It would have been magnifying the difference had I picked the less ripe. In size there was no perceptible difference between the fruits gathered and those left. Had the heavy crop been thinned probably greater size might have been obtained, but I do not thin, and made Grand Duke no exception.

Mr. Rivers' allusion to "ill-shape," which arose from compression, helps also to explain the cause of want of size. All the varieties of Plums grown on my hot sandy land at Girtford, especially such fertile varieties as Victoria and Grand Duke, are much smaller than usual, as, indeed, Plums are generally this year. I have looked upon Grand Duke as one of the best Plums grown, but it has never been very large, although last and previous years it has been much larger than this. That my stock of Grand Duke is true I have not the least doubt, as I have it from two distinct but most reliable trade sources, and both stocks have comported themselves alike. The last specimens of each I have forwarded to the

Editor for identification; also samples of Diamond, one of the parents of Self-help, now only partially ripe, although from a bush fully exposed to the south. As the Committee decided that Self-help was not so good as that variety, but here Diamond is the latest of the three, and quite a fortnight later than Self-help grown under similar conditions, and therefore the comparison is scarcely a fitting one. Mr. Rivers seems to think that the practice of sending specimens for comparison a reprehensible one. I had always thought there was a general invitation to exhibitors at the Royal Horticultural Society Committees to do so, but on reference to the regulations I find it comes only from the Floral Committee. I have seen the practice followed, and it seemed to me an instructive one, and it was with this view I sent Grand Duke in good faith for comparison to the Fruit Committee.

Mr. Rivers' letter raises a question whether it might not be desirable for the Committees, at their option, when exhibitors are willing, either personally or by letter, to furnish information as to their production, to allow the same to be furnished. A point of importance might sometimes be cleared up and a satisfactory conclusion arrived at.—THOMAS LAXTON.

[The fruit of Grand Duke received from Mr. Laxton was "dead ripe," and with the exception of one Plum was completely smashed in the carriage, so that it was impossible to judge of it. The shoots and foliage sent were not good specimens, and it was with difficulty we could judge whether the shoots were downy or smooth. To us they appeared to be smooth, whereas those of Grand Duke are downy. The flesh of the fruit was all but free, and that of Grand Duke is firmly adherent.]

SHOWY AUTUMN PLANTS.

At this time of the year of all others, when the majority of our bright-coloured border plants are on the wane, is the growers' time to look out for plants that will keep up the succession and extend the flowering season as far into the autumn as possible. Many plants are here and there in cultivation, though not by any means generally, that are suited for the above purpose; but unfortunately tastes differ to such an extent that the tall Asters admired by a few are passed over as unworthy of notice by others. Then Pentstemons may be mentioned, many of which are now in full beauty, reminding us of the rapid advances made by the hybridiser and selector within the last few years. Larkspurs, too, have undergone a similar change, and with the French varieties now becoming common we may represent every shade of blue and purple, from almost black to the most delicate tinge. It is, perhaps, not generally that these by a little management may be had to flower at almost any time from June until the frosts set in about the middle or end of October. They may be raised in the spring from seed, when by good treatment and liberal feeding the plants will flower all through the autumn months, or, again, when old-established plants have made about half their growth they be cut down they will also flower in the autumn, and indeed with a little experience, other circumstances considered, the grower can have them to flower at the time he is most in need of their assistance in making his beds and borders attractive. The very early flowering sorts may also be utilised in giving a second crop of flowers by cutting the stems off as soon as they have flowered. They will shoot up again, and though not so strong give a fairly good show, which is all that is wanted of them. Of course these second crops necessitate good treatment, but it is worth trying for, besides removing unsightly stems from an otherwise cheery flower border. Antirrhinums though past their best give hope of holding out for a few weeks longer, owing also to this judicious cutting-back process; indeed, it only wants a beginning and the grower will find that he can utilise many plants for second crops in this way.

Geranium Wallichii is now in its full beauty, and an extremely useful plant it is for the hardy border; no drought seems to incapacitate it for yielding its annual supply of pretty blooms, and in localities where success is attained with Lilies, *L. splendens* and its varieties will help in a very large measure to brighten the border. Given the necessary soil, with free drainage, a little shade for the bulbs, and plenty of water during the growing season, and this Lily will amply repay all extra trouble involved in getting it properly established. *Anemone japonica* and its varieties should also form part of even small collections. It grows well in almost any border, and its free-flowering habit should not fail to make it a general favourite. There are three colours—white, pink, and rose, the first being extremely chaste and beautiful; the pink, which has larger flowers, is also desirable, and to see these plants as we saw them the other day in the form of isolated specimens a yard through, it might almost make us come to the conclusion to grow nothing else for autumn decoration, but we want variety. *Rudbeckia speciosa* or *Newmanni* is a species of great beauty, and one that has attracted much attention of late. It is undoubtedly a fine plant and will play an important part in the bedding of the future. A large bed of the *Anemone* edged with *Rudbeckia* is strikingly pretty—a permanent

bed that does not require renewing every spring; a bed you can enjoy, and with no more trouble than clearing away the dead stems in autumn, adding a little fresh feeding every spring. Such beds, too, can be gay early in spring with Crocuses, Tulips, and Hyacinths without injury to either, and later with *Gladiolus*, giving a succession until the other plants are ready to keep up the display.—D. R.

WORDSLEY AND KINVER.

DURING a few days devoted to a horticultural ramble in the midlands this summer, I found myself within a convenient distance of Stourbridge, and the occasion seemed so opportune for paying a long-anticipated visit to a certain widely famed seed firm in that neighbourhood, that I determined to take advantage of it, and spend a day on the farms. For glass and pottery Stourbridge and the adjoining Wordsley have long been celebrated, but horticulturally they were of no importance until Messrs. Webb & Sons established the head-quarters of their seed business there, and since then for that fact alone they have become familiar to farmers and gardeners in most English-speaking countries. In the immediate neighbourhood there is little else of gardening interest, if we except Enville Hall on one side of Stourbridge, and Hagley, about an equal distance on the other side. But as my chief object was to see Messrs. Webbs' establishment, I proceeded at once to their

OFFICES AND SEED WAREHOUSES, WORDSLEY.

These are situated near the main road in Wordsley, and though prepared to see something extensive, I was astonished at the huge buildings occupied for this purpose, and the abundant evidence their contents afforded of an enormous business. The principal building is 180 feet long by 60 feet wide, and has five floors, another more recently erected being of nearly the same dimensions, and having an equal number of floors. These are devoted to the different departments, thus a large space is occupied with the flower seeds; the garden vegetable seeds form another, bulbs another, cereals also have a large space devoted to them, then the general farm seeds, such as root crops and grasses, in all of which a most extensive trade is carried on. Potatoes, too, have a floor appropriated to them for many tons of "seed tubers" are annually supplied from there, while Hops and wool, which are also branches of this diversified business, occupy a considerable proportion of one floor. It should be mentioned that these floors are all fitted with lifts, and in one part is a series of seed-cleaning machines of great importance, those devoted to seed corn being constructed on an improved system invented by Messrs. Webb & Sons, and are found to perform their work in a perfectly satisfactory manner. The value of thoroughly clean seeds can scarcely be overestimated, and the attention given to the matter by the members of the firm has met with well-deserved success. In an upper floor of the new warehouse we come to what might be termed the "theatrical lumber room" of the firm, for there the handsome stands are prepared which are seen at all the important agricultural shows in Great Britain, and which necessitate the constant employment of numerous carpenters, painters, and decorators. This department is doubly interesting, reflecting as it does to some extent the widely spreading character of the trade, and the enterprise brought to bear upon its maintenance and advancement. It is, indeed, a sign of the times.

The offices occupy a third building of great size; they are most systematically and conveniently arranged, permitting the multifarious details of such an enormous business being carried out with accuracy and dispatch, both essential to the satisfactory management of a concern like this. Large numbers of clerks are employed, and the manager of each department has a room in communication with the heads of the firm, who take an active part in the superintendence. There is also a house where grass and other seeds are tried, and with workshops of various kinds, stables, &c., completes an establishment that is in all respects wonderful.

THE SEED FARMS, KINVER.

But so far only the head-quarters had been inspected, and as a visit to the seed farms and trial grounds was equally desirable I was placed in the care of a genial, intelligent guide, and conveyed to Kinver as rapidly as our well-fed but meditative steed could be induced to travel. Fortunately plenty of time was allowed for a full enjoyment of the scenery, and a good portion of the four or five miles after Wordsley is left is decidedly pretty, especially when approaching Kinver, as there the road gradually ascends, at some parts through a deep cutting in the red sandstone of the district, with tall trees completely arching over the road, and at others commanding extensive views of an undulating and finely wooded country. It is, however, from Kinver Edge that the grandest views are obtained over many miles of Staffordshire and adjoining counties, a landscape which can only be equalled in this part of England by the prospect from the Malvern Hills. The seed farms occupy 1600 acres on the slope and around the Kinver Hill, which rises to and terminates in the precipice-like "Edge." The greater part of this land is Messrs. Webbs' freehold, being used chiefly as trial grounds or for raising stocks of new varieties, to be afterwards, with the bulk of the seeds required in the business, grown on land in various parts of England and the Continent, engaged for this purpose by the firm and under their personal supervision as to "rogueing." In this way it is estimated that over 15,000 acres are employed—an extraordinary total, the yield of which in weight of seeds could scarcely be calculated. One great advantage of this system is that the most suitable land for particular

crops can be selected, and the best produce is thus insured, well-developed and matured seeds of any cultivated plant being a most important step towards obtaining satisfactory results either in the farm or garden. To cereals many acres are devoted at Kinver; for instance, there are 180 acres of Wheat, comprising a number of Webbs' choice selections that have already proved of great merit, then there are 212 acres of Barley and 171 acres of Oats. No less than 78 acres are appropriated to Peas, and 63 acres to Potatoes, but to these reference will again be made, these numbers being cited merely to convey an idea of the relative proportions. Swedes, Turnips, Mangolds, and many other crops are all largely grown for the same purpose.

The first portion of the trial grounds that we visited was the "flower" department, where strains of the most popular florist and garden flowers are grown for comparison or improvement. In recent years much attention has been given to this, with the best results, and, as with the vegetables, farm crops, &c., careful selections have been made, which now bear the name of the firm as a guarantee of their merit. It would be impossible in these notes to enumerate all that are thus being tested, but a few of the more notable may be referred to. Tropæolums hold an important position in many gardens, and of these there are several handsome varieties, distinguished by their rich or delicately coloured flowers, such as King Theodore, extremely dark, and the dwarf compact King of Tom Thumb strain, in which golden yellow, creamy white, and dark scarlet tints occur. Mignonette is everyone's favourite, and a very fine strain has been obtained, with long bold spikes of flowers, powerfully fragrant, and the latter quality has been found to vary considerably in different strains. Such old garden plants as Antirrhinums and Marigolds are similarly well represented, while Asters of all the sections and Stocks, too, are as beautiful as such plants invariably are when of a good variety and well grown. Zinnias have been made a specialty, "Webbs' Exhibition Double" having secured much favour in gardens, the flowers being large, well formed, bright and varied in colours. The beautiful Chrysanthemum carinatum is largely grown, also C. atrococcineum, Godetias of the best varieties, the bright Eschscholtzias, with such well-known plants as Verbenas, Polyanthus, Calliopsis atrosanguineum, C. bicolor, Calendula Meteor, Malope grandiflora, Viscarias, Bartonias, Whitlavias, Asperulas, Eutocas, Candytuft, and hosts of other annuals, biennials, and perennials. All are deserving of praise, for every effort is made to render the selections thoroughly reliable and of the best quality, and those that I saw were good examples of the success that had attended these efforts. When large beds of particular varieties are seen as true as possible it is a satisfactory indication that the labour expended in selection and preservation has not been in vain. The popular plants, such as Primulas, Cyclamens, Cinerarias, Gloxinias, Begonias, and others are not grown at Kinver, but the same care has been exercised elsewhere in their improvement, and some highly commendable strains have been secured.

A most important portion of the routine at Kinver are the annual trials of vegetables, to which considerable acreage is fittingly devoted, the utmost care being employed in testing and recording the numerous varieties grown. The object of these trials is to permit a ready comparison between new and old introductions of each vegetable to prove their respective merits, and to enable the firm to determine what sorts they can recommend with confidence. The experiments are thoroughly and fairly conducted, the best seed is employed of each variety, they are cultivated in precisely the same manner, and the soil being a rich loam it is calculated to display the true characters of each to the best advantage. In every kind of vegetables Messrs. Webb have selections of their own which they test with the others, and in every case it was evident that the former had been chosen for substantial and valuable qualities that could not be mistaken, proving at once the good judgment of the selectors, and the advantage of such a mode of comparison as that adopted. To give a detailed account of all these trials would fill a volume, such as the Record Book kept at the Kinver Farm; but interesting as that would be, it is far beyond the scope of these notes, and I must confine myself to a brief mention of the principal crops. Of Cauliflowers forty-eight varieties or strains were being tried, but it was rather too early to determine their relative merits, though the home selection, Early Mammoth, was showing well, and certainly justified its title of early. Of Potatoes 500 varieties have been tested, but there are not quite so many this year, as a number that proved absolutely valueless have been discarded. Beans, including both Scarlet Runners and Dwarf Kidney varieties, were largely represented, a very good strain of the former being grown, and of the latter Victoria was noticeable for its large pods and prolific habit, while of the Butter Beans Wax Flageolet, Golden Butter-wax, and Wax Date were notable. Carrots, Parsnips, and Beet occupied much space, but one of the most interesting quarters was that appropriated to the Onions, of which fifty-three supposed distinct varieties were tested this season, one very obvious result being that a large proportion were found to be "too much alike" to deserve distinct names. The White, Red, and Yellow Globes were fine, but especially the first-named. The Flat Red and Italian Tripoli were also excellent varieties, the White Italian Flat Mammoth being remarkable for the great size of the bulbs, Danver's Yellow deserves prominent notice, and Improved Banbury was unquestionably one of the best varieties for size and evenness of bulbs. The other leading sorts were Giant Zittau, Giant Rocca, Blood Red, Brown Spanish, Bedfordshire Champion, James' Keeping, and Newnham Park.

Peas form such an important kitchen garden crop, that it is not surprising special provision should have been made for testing them, and accordingly no less than 128 varieties have this season been grown at Kinver, a trial which the home varieties Chancellor, Wordsley Wonder, Kinver Gem, and others have stood most satisfactorily. Several of these

have become great favourites in gardens, Wordsley Wonder especially having taken an important position owing to its good quality and prolificness. Turnips, Lettuces, and Savoys each formed interesting quarters, concerning which much could be said, while of Cabbages there have been fifty-five trials in addition to several acres of Emperor and New Early Drumhead for seed, the crop of the former being grand even samples of an excellent Cabbage. Numbers of other trials have been undertaken, and the results amply prove that the system is an admirable one.

Besides the several departments mentioned, it should be observed that a large trade has been developed in artificial manures, the works being at Widnes, Lincolnshire. Then to this must be added the non-horticultural but important glass-manufacturing business, where some exquisitely artistic work is produced, and it will be patent to all that the firm of Messrs. Webb & Sons is one of the most remarkable in the kingdom. The development of such a gigantic and diversified business indicates an astonishing capacity, and is in itself a sufficient proof that the true secret of commercial prosperity, high quality of productions, is thoroughly understood.—A VISITOR.

ORCHARD HOUSE CONSTRUCTION.

A PERTSHIRE correspondent and several others desire full information respecting the construction of orchard houses, and in compliance with their request we reproduce the following from Rivers' "Orchard House," the substance of which appeared in several articles published in early numbers of this Journal. The work in question gives a variety of other useful information on the subject that is indispensable to anyone intending to build such houses.

A LEAN-TO ORCHARD HOUSE.—Its length may be from 10 to 100 feet or more, according to means and space; but its breadth and height should be according to the following dimensions, unless any improved plan may be suggested which will insure greater advantages at the same cost:—

I will suppose that an orchard house 30 feet long is required. A ground plan 30 feet long and 12 feet 6 inches wide should be marked out. Then six posts of oak or good yellow deal, 5 inches by 3, and 10 feet 6 inches in length; or of larch poles, 16 inches in girth, cut in two, and the flat sides placed outwards, must be firmly fixed 2 feet in the ground: the ground ends, before fixing, should be charred 2 feet 6 inches from the bottom, and then have a coat of boiling coal tar, which adds much to their durability. They will form the back line of posts, standing 8 feet 6 inches in height from the surface of the ground. For the front wall six posts of the same thickness, 6 feet 6 inches long, must be firmly fixed 18 inches in the ground, so that they stand 5 feet out. Two posts will be required at each end (at one end, if only one door is wanted); these will form the door posts. On these posts, both at front and back, must be nailed a plate, 4 inches by 3, on which the rafters are to rest; the posts are thus arranged in two lines.

Now then for the rafters. These must be 14 feet long. A 9-inch deal—i.e., a deal 9 inches wide and 3 inches thick will make four, each 4½ inches by 1½, or nearly so. These are light, strong, and the most economical of all. Instead of "ploughing" the rebate for the glass (which is great labour and waste of material), on the upper side of each rafter, exactly in the centre, must be nailed a slip of half-inch board, half an inch wide; this will leave half an inch of the rafter on each side for the glass to rest on (not too much for glass 20 inches in width). The rafters are so far prepared for glazing, but not yet fitted on the plates at top and bottom of the projected house; no mortises must be made, but the rafter fitted to the back plate by cutting out a piece. They must then be strongly nailed to the front and back plates, leaving a space between each rebate of 20 inches. A piece of three-quarter-inch deal board, 6 inches wide, should be nailed along the top to the end of each rafter, so as to be even with their upper edges, and in this should be a groove to receive the upper ends of the pieces of glass. At the bottom a piece of board, 1 inch thick and 6 inches wide, must be let in, by sawing a piece out of each rafter, for the glass to rest on and to carry off the water. We have thus formed a sloping roof, 8 feet 9 inches (with the plate) high at back, and 5 feet 3 inches high in front.

The glazing is now to be thought of. This is best done by placing a broad plank, 5 or 6 feet long and 2 inches thick, across the rafters, for the glazier to kneel on. Two "brads" (small headless nails) should be driven into the rafter at the bottom corner of each piece of glass, so as to prevent its slipping down, which, with large pieces of glass, is very apt to occur; a bed of putty should be placed in each rebate for the glass to rest on, and the putty firmly placed over the pieces of glass in the usual way when it is fixed in its place. The laps should not exceed a quarter of an inch, and they need not be puttied, as the ventilation is more free when they are not. The most economical glass is 16 oz. British sheet-glass, which can be bought at 2d. per foot, and the size to be preferred 20 inches by 12, placing it crosswise, as the rafters should be 20 inches asunder. I find that scarcely any breakage takes place from frost, owing to the large pieces being elastic.

On and outside the back posts three-quarter-inch well-seasoned deal boards should be nailed. In the back wall thus formed, sliding shutters in grooves, 3 feet by 1 foot, must be fixed to act as ventilators—two close to the roof and two 18 inches from the surface of the ground (the lower shutters in the back wall must always be on a level with the ventilating shutter in front); if two more be added to the right and left of the lower shutters, all the better; in summer it is impossible to give too much air.

The front and ends (except the doorway) must also have three-quarter-inch boards nailed on outside the posts; one of them, the upper one in the front, to be on hinges, so as to let down the whole length of the house; this, with the back shutters, when all are open in hot weather, will ventilate thoroughly. To add to this, and it is all required in summer, the boards will shrink and let in air; a fierce sunlight is thus admitted by the large glass, and abundance of air, in which all fruit trees thrive to admiration. The boards and rafters should be painted with stone-coloured paint, which will give the house a very neat appearance.

If required, more head-room may be given by making a sunken path 2 feet 6 inches wide, and 4 to 6 inches deep, in the centre of the ground-plan

this will leave a border on each side 4 feet 9 inches deep. The front border need not be raised, as the trees in two or three years will require all the head-room they can have; but the back border should be raised about 12 inches above the surface, and supported by the brick or boarded edge to the path; for the sides of the path must be supported with boards or a 4-inch brick wall. The earth must be kept from the boards forming the back wall by a 4-inch brick wall. It will be found a great improvement (for which I am indebted to a friend) to divide the back border into two terraces by raising the back half 12 inches, building a 4-inch brick-wall, and filling it with earth, so that the back row of trees is elevated, and thus escapes any shade given by the front row; the effect also is very good. Now, as everything depends on these borders—for there must be no benches and no shelves—care must be taken to make their surface firm, yet the soil rather loose underneath: loose materials, such as lime-rubbish from old walls, and road-sand, may be laid on them about 6 inches deep; these materials may then have a coat of loam 2 or 3 inches deep, which should be removed to level hard surface; you thus have two borders, not too far from the glass, and on which your orchard will thrive admirably. It is now well ascertained that it is better to encourage the roots to come to the surface by rich surface dressings in summer than to allow them to root through the apertures at the bottom of the pot; hence the advantage of a hard border, which does not encourage excessive rooting below. It will appear odd to read about trees thriving on instead of in a border; but when I explain that this is to be an orchard in pots, it will not seem so contrary to our usual garden-culture.

A SPAN-ROOFED ORCHARD HOUSE.—Similar details to those already given apply to the span-roof house, but the following particulars are useful:—A small span-roofed house is so simple in its character that any self-taught builder or amateur may erect one. The way to do it is as follows:—Two rows of oak posts, 5 inches by 3 and 7 feet long, should be firmly fixed 2 feet in the ground; 5 feet out, 14 feet row from row, and 5 feet apart in the rows. On each of these rows should be firmly nailed a plate 4 inches by 2, to receive the lower ends of the rafters, which may be nailed on as directed for the lean-to house. The rafters should be 8 feet long and 3 inches by 1½; they can be bought at any sawmill, planed and chamfered, for 10s. or 12s. per 100 feet. The ridge-board should be 5 inches by 1, to which the upper ends of the two rows of rafters, after being sloped, should be nailed. As the glass cannot be made to fit on the plate at bottom, a drip-board, 5 inches by 1, placed sloping to receive the lower ends of the pieces of glass, must be fixed on the plate the full length of the house. On the ridge-board a small ledge must be nailed for the upper ends of the pieces of glass to rest on. On the upper edge of the ridge-board a cap, 3 inches by 1, should be nailed, to shoot off the water and prevent its entrance at the ridge.

Estimates of the cost of orchard houses are given in the work referred to.

EFFECT OF EARLY PRUNING ON VINES.

WHAT has become of our friend "A Thinker?" is a question frequently put to me of late, and all that I can suggest is that he is taking a long vacation. This we will not begrudge him, always providing he returns with plenty of fresh thoughts wherewith to interest and instruct us. By way of furnishing him and other readers with a little food for thought, I shall put into shape some ideas of my own on the subject of partially pruning Grape Vines while yet they are in full leaf. Perhaps it would have been better for me to have waited till I could have written more authoritatively, but, on the other hand, an early discussion of the whole subject may materially benefit and instruct numerous readers of this Journal who, perhaps, have never previously had their thoughts directed into the channels I propose to take them.

Grapes have been exhibited this season more largely than ever, at least such is my opinion, and in nearly every case the bunches will have been cut with a proportion, large or small according to the taste of the exhibitor, of the lateral growth attached. The consequence is many laterals have undergone a severe summer pruning, and according to the advocates of early shortening of the laterals, this should result in the formation of plump buds, which in due course would give extra fine bunches. According to my experience, however, the reverse is most frequently the case, and instead of better bunches, the next that are produced on that particular spur will be much smaller than usual. During the past three seasons I can truthfully assert that wherever I cut a bunch for exhibition purposes, none were available for a similar purpose the following year; and in the case of some partially renovated Vines of Muscat of Alexandria, some of the spurs from which show bunches had been cut broke badly the following spring, and completely failed to produce bunches. It is true the Vines in this case were in poor condition, principally on account of being overcropped so soon after they had been lifted, and in the case of some Black Hamburgs in the next house, and which had recovered their vigour more quickly, total failure did not occur. As a rule Vines that produce Grapes fit for exhibition are in good health, or perhaps we should have had others writing in the same strain as myself, and it may yet turn out that I am by no means singular in my experience. The idea prevails that the character of the bunches to be produced next season is determined this autumn, and so, doubtless, it is; but I am by no means convinced that those beautiful plump buds we all so much admire have a fine bunch or bunches in embryo already stored in them. It seems to me that the bunch-forming matter is rather stored in the wood about the buds. In proof of this, witness how frequently the closely spurred, and unduly closely spurred I should say, rods produce bunches, and that, too, from buds that previously gave no signs of being in existence. All the best placed leaves on the laterals contribute their quota to the formation of a store of bunch-producing sap, some being deposited in the young wood and the remainder in the main stem, and this, if I remember rightly, was to a certain extent demonstrated some time ago in the pages of the *Journal of Horticulture*. Thus, if we cut a show bunch we also remove important factors in next year's success; but, on the other hand, if

my theory is wrong, this severe shortening ought to prove beneficial, the two, three, or four reserved joints perfecting extra plump buds.

The thought may occur to some that, owing to the small number of laterals on the Vines that are subject to this severe shortening, the subject is hardly worth consideration, but I venture to think differently for several reasons. For instance, immense quantities of Grapes are sent to the markets, and naturally fruiterers prefer to have them with a piece of lateral growth attached; this, besides improving the appearance of the bunches, also rendering them more easy to pack or display in the windows. It follows that the majority of the laterals producing the bunches sent to the markets by some growers, are necessarily shortened, and this may slowly—but I believe most surely—lead to the ruin of the Vines, or at any rate to an ultimate material reduction in the weight of the crops resulting. This season my attention was called to an occurrence strongly corroborative of much that I have advanced above. The Vines in the centre of a large house, wholly planted with Muscat of Alexandria, broke very weakly and irregularly to the no small consternation of those in charge; but thanks to the extraordinary vigour of the Vines, they gradually righted themselves, and a good crop is now hanging on them. It was a lesson that will not be thrown away upon those responsible, and who happened to be intelligent men. From what I could learn the rods, in the centre of the house especially, had last season been rather heavily cropped, and in order to lighten the weight a considerable number of bunches were cut and packed for market. All were cut as if for exhibition, and that would appear to be the only solution of the mystery; at any rate, not much wood will again be sent away from that viney till such times as the leaves are fallen.

It does not follow that because I am of opinion that it is most injurious to severely shorten the laterals before the leaves are fallen, I would also condemn the practice of lightly shortening them. On the contrary, I feel confident that a judicious thinning-out of the sub-laterals and a moderate pruning of the laterals is a wise practice, and in this I am supported by one of the best gardeners I have ever met. He recently informed me that many years ago he practised early shortening of the laterals, some of his experiments tending to surprise most superficial observers. After the bunches are fully matured there is less need of so much foliage beyond them, the leaves say beyond the fifth or sixth joint from the rods merely storing up food that will eventually be cut away. All the Vines under my charge, both in early and late houses, now have the laterals shortened to about 12 or 14 inches in length, this leaving either five or six principal leaves, while all the sublaterals are cut clean away. In this manner, and with the assistance of fire heat, the best portion of the young wood will be thoroughly ripened, most of it, in fact, being now (September 16th) as hard as nails. It is the best ripened wood that produces the handsomest bunches, and it is the best ripened rods that will remain much the longest in good bearing order. While the Vines are growing strongly, this early shortening and thinning-out, if resorted to, would end in the premature pushing out of many back buds, but directly they cease to grow to any appreciable extent, then the pruning may be commenced, the shortening being gradually completed.—W. IGGULDEN.

NEPENTHES NORTHIANA.

AMONGST the numerous beautiful and cleverly executed pictures in Miss M. North's gallery at Kew is one that may be termed of historical interest, for it led to the introduction of one of the most handsome Pitcher Plants in cultivation. This represents a *Nepenthes*, which was named by Sir Joseph Hooker in honour of this distinguished lady artist, N. Northiana, and the exhibition of this painting induced Messrs. J. Veitch & Sons, Chelsea, with their customary enterprise, to send out a collector with the special object of finding and improving it. This, after some trouble, he succeeded in doing, and four or five years since it made its appearance in the unique collection of Pitcher Plants at Chelsea. The species is a native of Borneo, the head-quarters of the *Nepenthes*, and was found growing upon the limestone mountains in the neighbourhood of Sarawak, where several other members of the genus are also found, and another of Miss North's pictures (377) represents an undescribed species from the same district.

N. *Northiana* is remarkable for the size of its pitchers, being second only to N. *Rajah* in this respect, some of the largest having been found 16 inches in length and 5 inches in diameter. The pitchers are also very bold in form, with a broad grooved margin somewhat like N. *Veitchii*, the inner and outer surfaces being green, handsomely spotted and streaked with rich crimson. The form and markings are accurately shown in the woodcut (fig. 44), kindly lent by the introducers of the plant.

THE TALL-GROWING LOBELIAS.

THE tall-growing *Lobelias* are not so often seen in gardens as they deserve, for not only are they amongst our showiest plants, but the ease with which they may be grown, and their bright colours, render them most invaluable for outdoor autumn gardening. It will no doubt be all the better if they are planted in damp low-lying situations, excepting the *Tupa* group, as they are essentially moisture-loving plants; but this is not altogether imperative, for provided they are well supplied with water during

the growing season they will give satisfaction in the common border without special preparations. It is often urged against them that they are far from being hardy and unable to stand the test of an ordinary severe winter. In certain localities this may be so, but we in the south have never had any difficulty in preserving our plants through even trying autumns. Our plan, which is being generally adopted where known, is to cover the crown with conical heaps of cocoa-nut fibre or rough coal ashes.

types are *L. splendens*, *cardinalis*, and *fulgens* intense scarlet, and *L. syphilitica* blue, from which we get innumerable varieties.

To our taste there is no better way of setting them off to advantage than to plant them mixed in one bed; the effect is charming, and at this season one not easily forgotten. By much the same treatment *L. Tupa* may be had in our borders. A noble species, with its tall spikes from 6 to 8 feet in height, with about a yard on each of its peculiar scarlet

Fig. 44.—*NEPENTHES NORTHIANA*.

Never having lost a single plant, we can recommend with confidence to all those who have not yet tried it.

L. cardinalis, *splendens*, &c., are of an intense scarlet, not forgetting the florist varieties, for here, too, the florist has shown no mean skill in selection, the result of which may be seen in such plants as Queen Victoria, Prince Arthur, Painted Lady, Blue Beard, and others, some of which have extremely attractive foliage as well as striking flowers. One, however, that does not seem to be much in the trade we would like to draw attention to—*i.e.* *L. Milleri*, a hybrid supposed to be between *L. syphilitica* and some of the *cardinalis* forms. It has the foliage of *L. syphilitica* with the habit of the other, which it also resembles in form of flowers. They are a most beautiful violet, and seem to blend the blue of *L. syphilitica* with the intense scarlet of *L. cardinalis* or *L. splendens*. It is a free grower, about 3 feet in height, with fine straight upright habit. The

flowers. The large leaves are peculiarly attractive, covered as they are with a white down, and at a distance in contrast to the flower spikes very imposing. *L. Wallichiana*, or *pyramidalis*, a pretty Himalayan species, has bluish violet flowers; a first-rate border plant. All those mentioned may be readily increased by division of the roots in spring, and when grown in a little heat make good plants for autumn. Their flowering season extends from the end of July until the frost sets in.—T. Y.

AMERICAN BLACKBERRIES.

THE qualities of these have often been praised, and I have more than once decried them. I have never yet seen fruit in this country equal to the American pictures. It was one of these which induced me to plant

at first, and after I was fully convinced they were no better than our common wild variety I gave a few more varieties a trial, which I have done in a liberal way in every respect, and with no better results. The plants were put into the best position in the garden in the spring of 1884. They made capital growth last year and this one as well, but the fruits have been only moderate in numbers and no better in size or quality than bushels which we could gather in the woods about here just now. The Kittatiny variety was the first to deceive me, and now that the Lawton, Philadelphia, and others have proved equally useless nothing will induce me either to retain them or try them further. We might expect to find them plentiful in many gardens and at shows, but although I have visited many of both in England and Wales this season I have not once been able to find a dish of them in any way superior to our hedgerow kind. Indeed, I believe if this hedge one was taken into our gardens and fed, trained, and cultivated like those American kinds, that it would turn out superior to any variety ever imported.—J. Muir, *Margam*.

THE LONDON PARKS.

HYDE PARK.

THIS is by many considered the most important of the London parks ; more, perhaps, because it is the recognised resort of what is known as the fashionable world than for its superior attractiveness or extent.

Hyde Park covers some 400 acres of ground, so that, if second only in point of size, it is still of considerable extent. The land has been the property of the Crown for upwards of three centuries, in fact since the Reformation, when it was wrested from the monks of the Abbey of Westminster by the wily and unscrupulous Henry VIII. The manor of Hyde had been held by the monks for several centuries previous to the disestablishment, which reduced them from power and affluence to impotence and poverty, the Court and its satellites being only too eager to despoil the monasteries of their broad and fertile acres, on which their eyes had long been greedily fixed. The manor of Hyde was extensive and well stocked with game, hence it was soon seized upon by the king, to whose hunting preserves it made a welcome addition. It is not known with certainty when the park was first enclosed. The Serpentine, the broad piece of water which now intersects it, was formed about a century ago.

The floral arrangements are not conducted here, there, and everywhere in Hyde Park. Little will be found except in the splendid stretch of beds between Hyde Park Corner and the Marble Arch, and in the Dell and its surroundings, which will be subsequently alluded to. But in the beds referred to there is extent and variety enough to please the enthusiast. Scores of beds, of countless styles and designs, evoke admiration, and are alone worth a long journey to see. We will describe a few of the most effective of them. Starting from the Piccadilly end, a circular bed first attracts our notice. The centre is occupied by Pelargonium Princess Alexandra and Viola lilacina, the silvery-edged green foliage of the former contrasting nicely with the lilac-blue flowers of the Viola. A ring of the purple-leaved Iresine Lindenii surrounds the mass, and the bed is margined with blue Violas. It is exceedingly pretty. The next arrangement is a somewhat novel one, but is highly effective : the graceful foliage of Jacaranda mimosaefolia, which grows about 2 feet high, is contrasted with that of Fuchsia Sunray. Iresine Lindenii is planted here and there amongst them, and the bed is carpeted with the green Herniaria glabra. A line of Coleus splendens is planted along the front, and the whole is margined with a band of the silvery-grey Santolina incana. Equally novel and little less effective is an arrangement of Lobelia cardinalis, scarlet, 2 feet high ; Celosia pyramidalis coccinea, crimson plumes, 2 feet high ; and white Stocks. The bed is carpeted with Giant Musk, edged with Iresine, and margined with the pretty mauve-coloured Lobelia Omen.

One or two beds of Begonias are an interesting feature of the bedding here, and these plants might be more generally employed for bedding purposes, for which their adaptability has been pointed out many times. They grow to a convenient height, 1 to 1½ foot, and are very bright and varied in colour, besides being floriferous and hardy. The first of these beds we noticed was planted with Begonias in variety, with a ring of Pelargonium Mrs. Quilter, and a marginal ring of Lobelia Emperor William. It was very attractive, although the Begonias were not at their best. The next bed was attractive in a double sense ; it was planted with Heliotrope Jean d'Amour—a broad mass of dark blue, powerfully fragrant, and edged with Golden Feather and Lobelia speciosa.

Begonias in variety formed the most conspicuous occupants of another large bed. It was carpeted with Pilea muscosa, commonly known as the Artillery Plant. An edging of the slender-leaved variegated Grass, Poa trivialis variegata, heightened its effect, and it was margined with Lobelias. With the exception of the last-named, none of the plants mentioned is widely used for bedding purposes, though they look admirable thus arranged together. A good contrast is secured by the very simple arrangement of the pink Pelargonium Lady Bailey, Iresine Lindenii, and the large orange flowers and pretty leafage of Gazania splendens. These occupy another large bed, the Pelargoniums, of course, being in the centre. There are many large beds of Pelargoniums of different varieties generally arranged with Iresines and Ageratums ; they should be very effective when at their best, but the heavy rains last week dashed away many of the flowers. Nevertheless, in others that are somewhat sheltered the flowers are as plentiful and brilliant as ever.

A mixed bed of Acacia lophantha and Dianthus is attractive, the former having graceful foliage, the latter large flowers of diverse and

brilliant hues. These Indian Pinks are well worth growing by every one, being very gay ; they may be treated as annuals, for if the seed is sown early the plants will flower the same year. After flowering they may be pulled up to make room for other things, fresh seed being sown the following spring for the next year's display. A broad mass of Lantana Ne Plus Ultra, lilac, forms the distinguishing feature of another bed, a line of Coleuses, and a margin of Mesembryanthemum cordifolium variegatum completing it. A very pretty bed is formed by planting white Begonias, carpeting the ground with Alternantheras, a ring of Coleuses round the Begonias, and a marginal ring of Echeveria secunda glauca outside. An arrangement not previously observed is that of mixing Verbena venosa and Abutilon Thompsoni ; each grows about 18 inches high, the former having light purple flowers, which are borne with great freedom, the latter broad, prettily mottled leaves. The effect is good. The front of the beds is occupied with Pelargonium Queen of Queens, Iresine Herbstii, and a margin of Mesembryanthemum cordifolium variegatum.

The fine foliage of Solanum marginatum is shown to advantage in another example, while Nicotiana affinis, Polymnia grandis, and Pelargoniums in mixture are equally effective. Ficus elastica contrasts well with the slender leaves of Dracena congesta, and the bed is attractively completed by a pretty carpet of Abutilon vexillarium, lines of Pelargoniums and Coleuses, and a margin of Mesembryanthemum. It will not be necessary to give more examples of the different styles of bedding in Hyde Park, the beds described are but a few selected from dozens of others equally worthy of attention. There is variety enough to please all tastes, and the effect of the whole is superb.

Leaving the flower beds, the Dell near Albert Gate must be visited. It is, perhaps, the most attractive corner of the Park. Mounds have been thrown up and planted with various shrubs and flowering plants, while a stream of water runs through the lower ground, on the banks of which Grasses, aquatic plants, Palms, Tree Ferns, and subtropical plants are arranged with excellent effect. The Dell can be seen to good advantage from the bridge above. There is also a pretty mixed border of annual and herbaceous plants, such as Carnations, Pentstemons, Marigolds, Campanulas in variety, Stocks, Liliums, of which there is a large number, Antirrhinums, Gaillardias, Gladioli, and many other plants.

There is an attractive group of beds on the right hand side of the walk parallel with Rotten Row, just before the Dell is reached. One is composed of single and double Dahlias, which are now flowering splendidly. The colours are very brilliant, and there is plenty of variety. A ring of scarlet Pelargoniums and a margin of white Lobelias surround them. The other beds, which were chiefly composed of subtropical plants, are also worthy of notice, as is the beautiful border of mixed plants near.

From Hyde Park the visitor may pass into Kensington Gardens. A long border of mixed plants stretches on each side of the footpath, which starts from near the Albert Memorial and runs parallel with Kensington Gore almost to the end of the Gardens. This is not so attractive as it might easily be made, but the walk is a popular promenade. Some pretty flower beds may also be seen in front of the Ivy-covered cottage in the Gardens, which usually attract considerable attention. The beds in front of Kensington Palace should be visited ; they are prettily laid out. Pelargoniums in variety are employed very plentifully, and a long border composed of a row of Tagetes signata pumila at the back, then a row of scarlet Pelargoniums, next Ageratum, and white Lobelia in the front row, is particularly attractive.—P.

REGENTS PARK.

Although the recent heavy rains have considerably impaired the effect of the flower bedding in this fine park it is well worthy of inspection, and a visit should be paid at the earliest opportunity. Bedding is not conducted on a very extensive scale, nor is it particularly varied in character. There are no elaborate designs in carpet or ordinary bedding, but there are some very pretty beds and borders to be seen, and the effect is not less pleasant because secured by simple means. Many of our readers are probably aware that the flower beds in this Park are situated in what is known as the Broad Avenue, through which visitors pass on their way to the Zoological Gardens. The majority of the beds are arranged in one large group. They are composed chiefly of Pelargoniums of sorts, banded with Coleus or Iresine, and edged with Lobelias. The Pelargoniums have been very good indeed this year, but the rain, of course, has dashed many of the flowers to pieces, and much of the bloom has been removed in taking the cuttings required for next year's display. Notwithstanding this they still present a brilliant appearance.

Many of the mixed beds are noteworthy. We will describe a few of the most effective of them. A large bed of Fuchsias and blue and yellow Pansies, with the handsome foliage of Chamapence diacantha, had an admirable effect, which was enhanced by a band of scarlet Tropaeolums and a margin of Echeveria secunda glauca. We have seen few more effective beds than this. Several circular beds of Acacia lophantha, graceful in foliage, with an outer ring of the Marigold-like Gazania splendens, were also good.

In another large bed the gay flowers of the annual Chrysanthemums were contrasting with the broad handsome foliage and stately growth of Solanum marginatum, edgings of Zonal Pelargoniums and Pansies completing the bed. The pure white drooping flowers of Abutilon Boule de Neige were attractive in another example, which was carpeted with a fragrant mass of Musk, surrounded by a ring of scarlet Pelargoniums, and edged with Golden Feather. The prettily mottled foliage of Abutilon niveum aureum maculatum was seen to good advantage in a bed carpeted

with *Mentha Pulegium gibraltarica*, and edged with *Pelargoniums* and *Golden Feather*.

Some fine beds of *Cannas* and *Solanums* are imposing. The former are bordered by crimson *Pelargoniums* edged with blue *Ageratums*, and the latter by *Pentstemons*, varied and showy, *Pelargoniums*, and *Ageratum*. Subtropical gardening is not carried out on a large scale in Regent's Park, but what there is is effective.

One of the most brilliant beds at the present time is composed of single *Dahlias*, with bands of scarlet *Pelargoniums*, yellow *Calceolarias*, *Coleuses*, and the pretty variegated *Grass*, *Dactylis glomerata variegata*. The border itself is remarkably pretty, but the *Dahlias* are superb. The brilliancy and variety of colour in these beautiful flowers is remarkable. They are planted much more largely than the double varieties in the parks at the present time, and are unquestionably more popular.

Liliums are plentiful in Regent's Park just now, as also are *Gladioli*. Beds of these handsome flowers in mixture are as showy as anything that can be imagined. *Gladiolus brenchleyensis* is most largely grown; it is one of the earliest, and is of a brilliant scarlet colour. It should be grown by everyone. Many attractive ribbon borders are also noticeable. One is particularly good. It is composed of scarlet *Pelargoniums* in the back row, the silvery foliage of *Centaurea candidissima* in the middle, and blue *Lobelias* in the front.

Many handsome banks and borders of mixed shrubs and flowers also attract attention, and altogether the Park is well worthy of a visit.

THE BEDDING IN THE ZOOLOGICAL GARDENS, REGENT'S PARK.

Among the many garden improvements which have been effected in the public parks of London during the last six or eight years, I do not know of any where so much has been accomplished as in the Zoological Gardens, Regent's Park. Many who only know the "Zoo" imperfectly may be under the impression that it contains little or nothing of interest beyond a unique collection of representatives of the animal kingdom, but many of the houses which hold these are adorned with excellently grown plants, and the flower beds and borders are filled with a choice collection of the most improved forms of bedding plants. While going through these gardens several years ago I came away with the impression that the plants were rather scarce, and Mr. Young, the able Superintendent, must have been of that opinion too, as the capital stock now possessed proves that he knew what was wanted. The beds are beautifully furnished, and the vigour of the plants is all that could be desired. The display of flowers and the exceedingly rich colours of the carpet and foliage plants generally are highly attractive and very pleasing. Carters' *Prima Donna Lobelia* is largely used, and it is very pretty. At the flower garden in front of the refreshment rooms there are many circular, square, and other shaped beds, chiefly laid out on the grass. One side of it is edged with an undulating flower border 85 yards in length and 15 feet in width. Behind this there are many fine trees, to the immediate front the flower beds just referred to, and further on the garden generally. The border is planted ribbon fashion. The first line is a row of *Dactylis glomerata variegata* backed with *Viola Tory*, then comes *Calceolaria Golden Gem*, behind which comes in *Vesuvius Pelargonium*, white *Centaurea* being further back still, then the pink *Pelargonium Mrs. Holden*, and behind this the dark *Calceolaria Bijou*, the whole forming an old-fashioned beautiful border, just such a one as made Mr. D. Thomson's flower garden work famous at Archerfield, where, by the way, Mr. Young gained his first knowledge of gardening.

Amongst the small beds there are some beautiful carpet designs, *Alternantheras* being used in variety, and *Pyrethrum selaginoides* is used with telling effect. There are several beds of tall and dwarf succulents, which are interesting. The blue Gum Tree is used in several of the foliage arrangements. Some of them have been out for two years, and are 14 feet high. One bed with a centre of the Rev. F. Atkinson *Pelargonium*, edged with *Robert Fish Pelargonium*, and margined with Carters' Blue King *Lobelia*, was very pretty. Another with a centre of Mrs. Holden *Pelargonium*, edged with *Crystal Palace Gem*, and margined with *Vesuvius Tropæolum*, was very showy. John Gibbons *Pelargonium* was used in several beds, and its immense trusses of showy flowers were very attractive.

Several beds planted with *Phormiums*, *Palms*, *Cannas*, *Dracænas*, *Aralias*, *Castor Oil Plants*, and others of a tropical type were an agreeable change from the masses of flowers. *Dracæna australis*, with stems about 18 feet in height, and fine massive heads, is introduced here and there with grand effect. Herbaceous borders are extensive and well stocked. The small ponds, which are used for the accommodation of beautiful waterfowl, have some small islands, and these and the margins are clothed with many kinds of wild Grasses, Irises, &c., and appear as natural in aspect as any of the wilds in Scotland or Wales.

The best of all the carpet beds is one 51 feet in length and 12 feet wide, which is situated between the lions' dens and the antelope house. A number of lyres are distinctly traced out on various coloured grounds, the plants used being the choicest for this work, but as I fear my explanation would not make such a good piece quite clear, it will be best understood by a sketch I will send you at another time. Visitors here should not miss this bed. Going from the lions to the monkey house, and just in front of the bears' dens, there are some beautifully filled beds, one batch of figures being chiefly occupied with dark-leaved *Coleuses*, *Iresine*, white *Lobelia*, and Mrs. Pollock *Pelargonium*. There are many small *Palms* used in the centres, and this part looked as peculiar and interesting as any, the dark colour predominating so much as to give it quite an original appearance. Behind this there is a ribbon border, beginning with *Echeveria glauca*, followed with *Alternanthera paronychioides* major, *Snowball*

Lobelia, Young's Seedling *Tropæolum*, very bright Flower of Spring *Pelargonium*, *Ageratum Her Majesty*, and *Golden Harry Hieover Pelargonium*. Amongst flowers Henry Jacoby *Pelargonium* is very conspicuous here, and all the best of Messrs. Pearson's *Pelargoniums* are used with capital effect. Near to the western aviary there is a large border filled with the different varieties of East Lothian Stocks, the plants being very healthy and promising well for a fine display of fragrant double flowers.

On coming in at the main entrance there is a straight walk 90 yards in length, and on each side of this there is a border filled with subtropical plants backed with shrubs of many choice kinds. Near to the band stand there used to be a great want of shade, but this has now been obviated in a great measure by moving some very large Lime trees to this part. They are specimens 20 feet or more in height with fine bushy heads, and they have succeeded uncommonly well, being well clothed with leaves, and giving pleasant shade. The main stems and the largest of the branches have been incased in hay bands, and in warm dry weather these are moistened occasionally, which keeps the bark from shrivelling. This transplanting was a heavy undertaking well managed.—L. L. M.

NOTES ON GRAPES AT THE RECENT EDINBURGH SHOW.

GRAPES were shown in great quantity and remarkably good quality at the Show in Edinburgh. Of course, there were some bunches of the late varieties that were hardly ripe, but it was apparent that only want of time was to be held accountable for that deficiency. Another month would have seen them in greater perfection.

Among the comparatively new Grapes shown Alnwick Seedling was conspicuous for its fine appearance. It is eminently suited for an exhibition Grape, and is really a fine-looking variety when seen as displayed in Edinburgh.

Madresfield Court was hardly "up," but still was shown in good style; evidently it does not crack with everyone.

Duke of Buccleuch was seen to advantage. Two baskets exhibited by Messrs. Thomson, Clovenfords, attracted much attention, and received a special award from the Judges for "packing and general excellence." There were 24 lbs. in the two baskets, packed as if for market, not a speck of bloom being removed or a single berry shaken. Mr. Kirk, from Alloa, had a grand bunch of the "Duke," the berries being enormous and very regular. Another fortnight would have added the golden hue that was the only thing required to make the bunch perfect. Mr. McIndoe showed it in good condition.

Golden Champion was also exhibited in fine order, not a trace of the "spot" that sometimes is seen disfiguring it was visible. The berries were of a beautiful transparent amber colour that showed it was in proper condition for the dessert table.

Duchess of Buccleuch was also shown in first-rate condition, the berries being quite golden. It carried the day for the best-flavoured white. It is pleasant to notice that the last three mentioned Grapes, which have all been the subjects of much difference of opinion, and have been the cause of much warm discussion in the horticultural papers, are grown and appreciated by not a few. Anyone seeing them as displayed at Edinburgh last week must be very prejudiced if they did not admit that they are Grapes worthy of the utmost care and attention, as, when successfully grown, they are most delicious, and in the cases of the Champion and Duke also most splendid in appearance.

Gros Maroc was also seen in grand condition. It evidently will be more and more grown as years roll on. Its place will undoubtedly be as a Grape for use about the end of October and in November. Nothing can exceed it for a black Grape for market about the time mentioned; its wonderful bloom, grand berry, and compact bunch all make it look handsome in baskets or trays. Though deficient in flavour, it is not much behind Alicante in that matter, and may fairly claim equality with Gros Colman.

Golden Queen was also displayed to advantage, some very nice bunches, good in berry and well-coloured, being staged.

Taken altogether the Grapes were good, allowance, of course, being made for the exhibition of a few bunches that only required time to make them right. At the Show which is to be held in Edinburgh in November it may be expected that many late Grapes will be shown. They will then be more in season.

Mr. Hammond deserves great commendation for the splendid style in which he brought his Grapes across the border, and staged them in the "grey metropolis of the north." There is some talk of having an exhibition next year which would approach an "international" in connection with the General International Exhibition which Edinburgh hopes to have next season. If anything comes of the suggestion, every effort, it is to be hoped, will be made to have a grand display of Grapes from all quarters. To procure this, handsome prizes must be offered. However, whether such an exhibition be held or not, it may safely be said that Grape-growing is being carried on in the country by many with conspicuous skill and apparent success. Long may this continue! Long may we see tables groaning under heavy loads of first-class Grapes at all our autumn and winter shows!

A word of advice to young gardeners anxious to shine in competition was spoken at the dinner in connection with the Show by Mr. Hammond. It is worthy of remembrance by all. He said:—"Let me counsel all young gardeners to remember that their first duty is to serve their employers well; to crop Vines and other things, not solely with a view to showing, but to meet the requirements of their situations. Then if there are Grapes or other things fit to show, and employers consent, let them

exhibit and reap their due reward." If this advice is acted upon by any young man beginning his career as a head gardener, he will, I feel sure, never regret doing as Mr. Hammond suggests. Too many employers have cause to feel annoyed at "showing" being considered before themselves, and it is not to be wondered at that they sometimes stop it.—S.

BEDDING VIOLAS.

I HAVE read with pleasure the remarks of your correspondent, Mr. W. Dean, at page 178, concerning these both charming and useful bedding plants. I can endorse much which he has written respecting them. As Mr. Dean very rightly observes, the hot dry weather has thoroughly tested the staying powers and constitutions of these plants; not that we should discard them on this account, for the test has been exceptional, and not a few will discover which have suffered most—the late-spring or the early-autumn-planted. If spring effect is desired the earlier planting is done in autumn the greater the chances of success; if for summer bedders transplant in autumn. Whether or not the *Viola* suffers most in dry summers in light or heavy soils I have not quite determined. There are drawbacks in both soils. Deep cultivation and heavy mulchings of short manure, spent hops, or similar material, is the means of avoiding the evils of a dry season. Yellow Dwarf, the gem of all yellows, scarcely exceeding in height that of the general strain of *Lobelia*, unequalled in its floriferousness, has suffered terribly this season, and I doubt if a sufficient stock will be saved to keep up the supply. The same remark may be applied with equal force to the majority of the Queen of Spring strain, from which Yellow Dwarf is a seedling. These lack the constitution requisite to carry them through such a summer as this has been; and seeing that constitution is of the highest possible value in connection with these for bedding purposes, we have yet to continue our experiments in this direction, and endeavour to obtain size of flower and free blooming with the compact habit of Yellow Dwarf, and at the same time possessing the vigour displayed by *lutea perfecta* and *Ardwell Gem*—the latter a primrose, an early and continuous bloomer, very desirable. Failure seems very general among the yellows, while at the same time whites, blues, and purples can be spoken of much more favourably. Even at this late date (September 10th) I have lovely blossoms of Countess of Hopetoun, which, as a white, surpasses any variety known to me. It is of short sturdy habit, and free flowering. Next in whites is the highly fragrant Mrs. Gray, and then if we want the other extreme for contrast we can get supplied with it in Archie Grant, an exquisite dark violet blue, with well-rounded flowers, and a capital summer bedder; but as a spring bedder nothing can equal True Blue. It is well to remind the readers of the *Journal* that these *Violas* are among the most useful and attractive plants in the spring garden, and that it is impossible to overrate the value of many for general decorative purposes.—J.

CECIL LODGE, ABBOTS LANGLEY.

CECIL LODGE, the country seat of Howard Gilliat, Esq., is situated in the quaint old parish of Abbots Langley in Hertfordshire, and not far distant from the main line of the London and North-Western Railway. The ride from Euston to King's Langley, which is the nearest station to Abbots Langley, the lakes being about a mile and a half distant, occupies about three-quarters of an hour, during which you traverse an interesting portion of Middlesex and the picturesque vale of Herts. The latter county, or rather the portion through which you pass to King's Langley, is boldly undulated, the frequent ranges of hills richly clothed with trees, the pleasant well-watered and cultivated valleys, with peaceful-looking rural farmsteads, and villages with their quaint old-fashion churches, are scenes which make a favourable impression on the traveller.

Two centuries ago these peaceful valleys were not so quiet as they are now, as hereabouts during the wars of Cromwell were many conflicts. But it is not so much with the history of the county that we are now concerned, as with the gardens of Cecil Lodge. Accordingly, alighting at King's Langley, a walk of a mile and a half, nearly all uphill, brings us to the prettily situated house of Mr. Vincent, the able gardener at Cecil Lodge. Mr. Vincent's domicile is some distance from the garden, but it is comfortable spacious house, with a considerable amount of lawn in front.

The mansion is a commodious structure of a not very elaborate style of architecture, and was, previous to Mr. Gilliat coming into possession, the residence of the Right Hon. W. H. Smith, M.P. It is situated in a somewhat elevated position, and commands extensive views of the charming scenery of the surrounding country, with Welling Abbey in the distance. The general style of the pleasure grounds is very pleasing, there being a boldness of outline and originality of design not frequently met with. There has not been any attempt to introduce a number of meaningless walks, and thus cut up and disfigure the beauty of the lawn, neither are too many beds allowed to interrupt the view from the principal windows. Beds of Roses, Pansies, *Polyanthus*, *Mignonette*, *Heliotrope*, *Pelargoniums*, and other useful and sweet-scented flowers are skilfully disposed on the margins of the lawn, and borders of old-fashion flowers form a margin to the shrubberies.

A few remarkably fine specimens of Conifers are a special feature in the pleasure grounds. A thoroughly robust and handsome specimen of *Abies Smithiana* has attained a great size, also a *Pinus insignis*, *Cedrus Libani*, and *C. Deodara*. There is a noble example of the Oriental Plane, and a similar one of the British Oak, which cover a large area. A large specimen of the Judas Tree (*Cercis siliquastrum*) is there, as well as a few other important shrubs and trees. The grass seemed of a very fine texture,

and is kept in excellent trim. One not very common feature was a number of bulb beds formed by planting Crocuses of various colours and Daffodils in geometrical outlines under the shade of the large trees. In the spring these bulbs shoot up and flower through the sward, and being planted with various colours, they are very effective. The majority of the bulbs had, we believe, been planted for years. This simple plan is therefore commendable to everyone who can afford to plant a few bulbs under the shade of trees for spring flowering. Passing towards the vegetable gardens we entered the Rose garden, which contains some of the best varieties. On the one side of the latter is a small lake, in which Water Lilies abound, and quantities of the *Fleur de Lis* (*Iris Pseudacorus*). On the Rose garden side of the lake is a series of beds devoted to growing Watercress, which is in much request for the family winter and summer. These beds are about 4 feet wide and 1 foot deep, the sides and bottom being of brick cemented over. There is a small tap at the top end of the beds, and through this water is kept constantly trickling at a slow rate, thereby causing a constant motion and supply of water to pass through the tanks. The beds are renewed twice a year, in the autumn planted with Winter Cress, and in the spring with Summer Cress. These beds are very satisfactory, and where this salad is esteemed, and space permits, a small bed might easily be managed.

The vegetable garden is of considerable extent. Good crops of Peas, Onions, Potatoes, and indeed all kinds of vegetables, are grown in the best possible condition. Bush fruit and Strawberries exist in quantity, and a few good trees of Pears, Plums, are to be seen on the walls and the sides of the garden only. A bower of skilfully trained Pear trees is formed over the meeting points of the four walks in the centre of the garden. This serves a twofold purpose—affords a shady arbour, and produces fruit at the same time. New borders are being formed on one side of this garden for growing the best varieties of herbaceous plants. There is an outside slip to the vegetable garden which is planted with standard Roses, and also acts as a nursery for raising plants for spring bedding and other purposes. There are some pleasant walks around this, and some fine specimens of *Wellingtonia gigantea*, *Pinus insignis*, *Cryptomeria japonica*, *Cupressus Lawsoniana*, Cedars, &c. One of these walks leads to a pretty dell, skilfully formed of rockwork, and consisting of miniature waterfalls and caves.

The vineries, Peach and Fig houses are situated along the top of the vegetable garden, and although the former are not of modern construction, yet Mr. Vincent does not fail to make them answer his purpose and produce good samples of Grapes, though he has for want of room to make his vineries do duty as plant houses too. One house has, in addition to Vines, to grow pot Roses, another *Geraniums*, and so on, to supply the requirements of the family, who reside for a greater part of the year in town. Another house was carrying a heavy and well-finished crop of Black Hamburgs, another Muscats, and so on. A house in the centre of the range is full of useful stove plants of a miscellaneous type, another house to growing Roses, such as *Maréchal Niel*. There are two Peach houses, and both are filled with healthy free-bearing trees of Royal George, Late Admirable, and Rivers' Orange Nectarine.

The Fig house is a special feature, as it certainly deserves to be, for better grown and fruited examples of Brown Turkey we have never seen. The trees are trained on a trellis close to the glass, and nearly every shoot was carrying fine fruit. Plenty of water and abundance of air appears to be Mr. Vincent's practice. Tomatoes were being grown in pots against the back wall of this house, and very good they were.

In another portion of the vegetable garden there is a very large span-roof orchard house, in which there are planted out along the sides Cherries and Peaches, and in the centre standard Peach and Nectarine trees, all of which were carrying a more or less heavy crop of fruit. Mr. Vincent grows a vast quantity of the best varieties of *Chrysanthemums*, which he finds to be of great service to him in keeping up a supply of cut bloom from November until an advanced period in the new year. This large orchard house is specially valuable for housing such a great quantity of *Chrysanthemums*. Another span-roof structure, divided into two compartments, is filled, one with Cucumbers, and the other used as a propagating house. Frames are filled with the lovely Neapolitan Violets. This variety Mr. Vincent prefers to grow entirely in a frame, and his plants certainly testify that he is doing the right thing. Adjacent is a Mushroom house, which is used chiefly for winter work, the young men's rooms, tool, and other sheds. Water is rather scarce here, and what they have has to be pumped up by means of a steam-engine from a very deep well in the garden, and then forced up into an immense tank raised on powerful iron columns connected by powerful traces to the height of 100 feet. The water from this tank can thus be forced to any part of the grounds. Taken altogether, our visit to Cecil Lodge and Abbots Langley was a very pleasant one, and although we have not dwelt in detail on all the many objects of note, yet we saw the good effects of the marked improvement which Mr. Vincent is gradually making under many difficulties in the several departments of the garden under his charge.—T. W. S.

CEANOTHUS DENTATUS.

WITH a few exceptions the plants of the Buckthorn family are not remarkable for the beauty of their flowers; the *Ceanothus*, introduced to this country from California, will, however, do much to increase the interest attached to this tribe. The flowers are, individually, very small, but this minuteness is fully compensated for by the profusion with which they are produced. The foliage, too, is extremely neat, especially in the

species selected for our illustration, and which is, perhaps, the most interesting of the genus. Some fears were entertained that the *Ceanothus dentatus* would prove only half-hardy; the specimen from which our figure was drawn was, however, taken from a plant which had been fully exposed on a south wall throughout the winter without any protection whatever, and as its capability of resisting our winters will doubtless increase with the age of the plant, we trust that this charming species may be considered acclimatised. Like many other shrubs cultivated in the open air, it would probably suffer considerably from severe frost; but as the peculiar habit of growth, both of *dentatus* and most of the other species, renders it desirable that they should be planted against a wall, the protection of matting can be afforded them without entailing much trouble or expense.

The *Ceanothus dentatus* is a branched evergreen shrub, growing to the height of 7 or 8 feet, perhaps more. The whole of it is covered with down, that on the branches being of a rusty colour. The leaves are very small, the largest scarcely exceeding three-quarters of an inch in length, with coarse teeth, a revolute margin, and a pair of small scale-like stipules at their base. The foliage has a peculiar, but to us not unpleasant odour, due to the numerous minute glands on the edge of the leaves, which are, however, hardly perceptible without the aid of a lens. These glands are said to be found only on this species, and they afford therefore

Fig. 45.—*Ceanothus dentatus*.

a ready means of discrimination. The flowers are produced in stalked heads, sometimes roundish, but in the wild plants much longer. Although small, the number in each head is considerable, and their bright bluish-violet tint gives the plant when in bloom an exceedingly attractive appearance. A detached blossom is represented on an enlarged scale in the corner of our engraving, chiefly for the purpose of showing the peculiar form of the petals of the plants of this order. These, it will be seen, are much longer than the sepals; narrow and hooded (cucullate) at the tips in a curious manner, the stamens being inserted opposite the petals.

With regard to the culture of the different species of *Ceanothus* from California, they all appear to thrive in peat, either alone or mixed with a little loam. Their growth is somewhat straggling, and the shoots, therefore, require frequent stopping during the summer; but as the flowers are borne upon the shoots of the previous year, this shortening process must not be performed late in the season. In the Osborne Gardens *C. dentatus* is trained on the horizontal system, and after flowering the secondary branches are shortened back to within an inch or two of the main laterals.

The species are readily propagated by seeds, which are sometimes matured, and which should be sown soon after gathering, or they will no

readily vegetate; they may also be increased by cuttings of the half-ripened wood under a handglass.

We have selected *dentatus* as being, on the whole, the most desirable species; but it forms but one of a group introduced, we believe, nearly about the same time, by the Horticultural Society's collector, Mr. Hartweg, and which are all well deserving attention. The *C. papillosus* and *C. rigidus* are scarcely less interesting than that we have figured, and are a shade more hardy; indeed, we believe they may be said to be perfectly so. The foliage of *C. papillosus* is much larger than that of *dentatus*, and has its surface covered with pimple-like elevations, to which it owes its specific name. It is of more vigorous growth than the Toothed *Ceanothus*, and may be treated in a similar manner. *C. rigidus* fully equals in interest *papillosus*, but is less branching in its habit. It is, probably, hardy enough for cultivation as a bush or standard in this country. Two species of more recent introduction, *C. floribundus* and *C. Lobbianus*, deserve especial mention as highly ornamental subjects. Both have blue flowers copiously produced.

One species, the *C. americanus*, is known as the New Jersey Tea, from the circumstance of its having been used in the American War of Independence as a substitute for the Chinese plant. Numerous varieties of this deciduous species have been raised in European gardens, some of which are well deserving of cultivation. As we may not soon have occasion to notice this order again, it may be worth while to remark that to the Buckthorn tribe belongs the Lotus of the ancients and the Jujube tree, both of them species of *Zizyphus*, though the articles sold as jujubes probably contain as much of the genuine fruit as the perfumer's bear's grease does of the real Bruin.—W. T.

NOTES ON CHRYSANTHEMUMS.

CHRYSANTHEMUM PROSPECTS IN THE NORTH.—Lately I have had an opportunity of seeing a great many *Chrysanthemum* plants in the neighbourhood of Liverpool, and, judging from their appearance, I look forward to seeing some grand flowers from that locality during the coming season. The weather there has been specially favourable to the growth of the plants, which have had plenty of sun and refreshing showers from time to time. The weather in the south of England has not been near so favourable, as the drought has been so long-continued and the sun more powerful, causing the plants to require more water during the day, which is not always favourable to their well-being, particularly if at all neglected, as is sometimes the case through stress of work in other departments. The plants I saw in the north had made strong growth, while the foliage was leathery, luxuriant right down to the pot, and of a red green colour, a sure indication that they were "doing" as well as could be wished. The buds were being "taken" at a suitable time for the varieties, and were of good shape, not a small item in the successful production of good flowers.

Chrysanthemums are increasing in popularity in that district judging from the number of plants now grown. Liverpool has long been noted for the production of the best specimens of cut *Chrysanthemums*, and now that growers in other parts are running them hard a greater spirit of emulation has set in to maintain the reputation gained in years gone by. The varieties have increased, too, generally, and vast improvements are noted now in the colours, which are much more decided than formerly, and this not at the expense of size or form. I look forward to seeing several new good varieties during the coming season. As interest increases so does the craving for novelties, hence the cause of so many worthless varieties being pushed into commerce; it is a sure sign that they are more appreciated now than was the case some few years since, judging from the number of societies which offer tempting prizes. It has been said that *Chrysanthemum*-growing is only in its infancy; this I question very much. If such great changes are to take place it must be done by the introduction of an entire set of new varieties, as I fancy that all has been obtained of existing varieties that can be had by cultivation; and my opinion in this is shared by many good growers having a wide experience.

EXHIBITING CHRYSANTHEMUMS.—The remarks of "*Chrysanthemum*" (page 245) on exhibiting are well timed and very sensible. It is a question which has puzzled not a few exhibitors. It is a well-known fact that it is much easier to set up a stand of twenty-four blooms in eighteen varieties than to have them all distinct; it is generally the last two or three blooms that spoil an otherwise good stand. I have an idea that the rule of admitting eighteen varieties in a stand of twenty-four blooms has been created by members of committees who know the trouble entailed in staging twenty-four distinct as a way out of the difficulty. The managers of societies also know quite well how much more massive a stand of twenty-four blooms looks than one of eighteen only, while more competitors can be obtained where eighteen varieties in twenty-four blooms are required. Making a show attractive to the ordinary spectator and satisfying all "critics" is difficult to manage successfully in all cases. No comparison can be made between two stands of flowers, one having eighteen varieties only, the remainder duplicates, and the other stand of twenty-four all distinct. I have heard many people say how much superior was one stand of blooms to another when comparing two staged as stated above, but if the duplicate blooms were withdrawn and others substituted

to make it distinct, a great difference would be noticeable as compared with the former occupants. I consider judges are quite right in awarding the prizes to the eighteen variety stand over the one with twenty-four distinct (of course supposing the necessary quality to be there) for the reason that a bloom of Lady Slade, for instance, no matter how good it may be, cannot compare with a duplicate bloom of Lord Alcester or any other of the Queen family. As long as an exhibitor complies with the conditions of the schedule that is all that is necessary. If it is considered to be a fault offering prizes for twenty-four blooms in eighteen varieties, the remedy is quite easy in making the classes for eighteen blooms only, and they to be all distinct. For my part I have no fault to find with the system. I am thoroughly content, as an exhibitor, to leave the decision of awarding the prizes in the hands of the judges.

For the information of "Chrysanthemum," I may say that when I have completed the experiments I have in hand I hope to redeem the promise I made in a former note, as no writings which I have yet seen make the matter sufficiently clear to the inexperienced grower.—E. MOLYNEUX.

EXHIBITING CHRYSANTHEMUMS.—Your correspondent, "Chrysanthemum," in the last paragraph of his note has done what I had thought of doing—namely, given Mr. Molyneux a reminder of the promise he made some months ago, and which up to now he has failed to fulfil. It was just as the Chrysanthemum season was drawing to a conclusion that he treated us to a little lore in the Journal, but since then we have heard nothing from him on the subject, although, no doubt, many like myself have been on the look-out for what he promised. My object of the writer is to induce him to write if he will, although it would not be of much benefit this season to us. I hope Mr. Molyneux is not one of those men who does not intend for others to benefit by his teachings; he may have many grounds for excuse, which no one can deny, but I should hardly fancy he can see "a red light."—A YOUNG BEGINNER.

EXHIBITING CHRYSANTHEMUMS.—With reference to the letter from "Chrysanthemum" in the Journal of the 17th inst., I take it that one object of societies in providing classes for twenty-four blooms of not less than eighteen varieties, is to secure the most imposing stands possible. Therefore it follows almost as a matter of course that a stand of eighteen varieties would take precedence over one of twenty-four varieties, but with some smaller blooms, notwithstanding that in the case of the latter it might be that their natural growth was smaller. If this were not so we should soon have small varieties, say Mrs. George Rundle, taking equal rank with Empress of India.—WORDSWORTH.

CHRYSANTHEMUMS AT THE TEMPLE GARDENS.—The plants at the Inner Temple are looking well, and Mr. Newton is making his usual preparations for the annual display. This will be held in the glass house near the Thames Embankment, a very convenient position for visitors. I am informed that there is to be no public exhibition of Chrysanthemums in the Middle Temple this season, but I hope the rumour is unfounded, for Mr. Wright has so steadily advanced the character of the show there that it deserves to rank amongst the best in the metropolis.—A.

TREE PÆONIES.

(Continued from page 258.)

For this purpose select two or three-year-old wood, with plenty of buds upon it, cutting it to single eyes, and at the same time removing one half of the wood, or, in plainer language, adopt the means employed in budding, excepting that in this case the wood must remain with the bud, and not detached from it: the plants thus raised, though small, are best adapted for pot culture. The next mode is by grafting, which is the best means of all, and attended with such good results generally that for general use it is the most expedient. The present is a good time, as there are plenty of good plump buds ready, and then comes the stock, which is generally to be found in most gardens. *P. edulis* makes the best stock, though they may be grafted upon almost any of the herbaceous section. Select some ordinary-sized tubers of these, and having obtained good buds (avoiding flower buds as much as possible), graft them in the usual way, tying them firmly, and making them air and watertight by means of grafting wax. They may then be potted, using pots according to the size of the fleshy roots; and to avoid using larger pots than necessary, for these roots will not bend in any way, it will be well to select moderate-sized tubers for stocks, for they need to be buried below the graft, which is better performed in the potting than by any after covering. When sufficient has been done they should be placed in a cold frame or pit, and if plunged in cocoa-nut fibre above the rim of the pots, so much the better. They should not be watered for the first few days. This, however, depends on the weather itself at the time the operation is performed, and consequently the operator will have to use judgment and discretion in the matter. They will require to be kept close during the first two or three weeks, and shaded on all sunny occasions. A union between stock and scion will have taken place by this time, when air may be admitted to them. In this place they may remain till spring, and being plunged will require little or no water, and at the same time be safe from frosts. It must not be overlooked that in all cases of after-management care must be taken to bury them below the graft, from which point they will in time emit roots, and consequently be not wholly dependent on the stock for their support. The last means of propagating them is by seeds, an operation of great interest, seeing the success which has attended the labours of some continental florists, and which have

resulted in the gigantic blooms of which I have already spoken. Nor is there any reason why they should rest here. The seeds are best sown as soon as fully ripe, and provided they do not germinate by the spring of the year ensuing, they may be placed in gentle heat. The progress of the young plants will depend to a great extent upon the liberal treatment which they receive.

Before concluding these remarks I have yet one more point in favour of their more general use, this time as pot plants for conservatory decoration. These may be had in flower in the early part of February without undue forcing, and should be protected in frames and brought on gradually. And who will gainsay the telling effect which a few will produce? There is yet time to procure them and give them a trial, for it well repays the outlay; and having once tried them, I feel sure that many will be aroused to a full sense of their usefulness and high decorative qualities, and that ere long these noble plants will be lifted from their now neglected state to that prominent position which their merits entitle them to hold.—E. JENKINS.

CACTUSES.

It is astonishing what an interest the New Orleans Exhibition has awakened in Cacti. True, they only need to be seen to be admired, and yet the majority of florists cannot bear them—perhaps because there is no money in them. I have a collection of about 400 varieties, mostly small plants, but good bloomers; and even when not in bloom they are always interesting to me. To watch the plants grow, develop their many-coloured spines, form their huds, expand their beautiful flowers and bring forth their brilliant seed-pods, is to me just as fascinating as to look over a collection of valuable paintings. When I say florists can't bear them I must except our friend Mr. John Thorpe, who in answer to that imputation writes me as follows: "You are mistaken when you say I hate Cacti; I love them, but in this greed to live there is no opportunity to make Cacti what they will be in twenty-five years. When I tell you that two of my most intimate friends are Pfersdorff of Paris, a man that has actually slept with a Threthead for his pillow, and Mr. Peacock of Hammersmith, London, who has had *Cereus cylindricus* for a bed-fellow, you will not say your friend John Thorpe hates Cacti." Mr. Thorpe, by the way, has probably the finest *Pilocereus senilis* in this country. It stands 46 inches high.

Although for some years I have been supplying leading European houses with rare Cacti, yet I found it almost impossible to get anything like a complete collection for my private use; so at last I have concluded to send to Europe for specimens of every variety catalogued there, which amounts to nearly 900. It is probably about the best way to get them correctly named, which is a very important item. I have had much trouble in this respect, with some thirty correspondents in Mexico and out West. Ask them for *Echinocactus Sileri*, *Astrophytum myriostigma*, or the Red Night-blooming *Cereus*, and they answer: "Oh, yes, we have them." When at last you pay ten dollars expressage on a box of samples, you get some *Opuntias* or a *Cereus peruvianus*.

Many Cacti may well be grown for their beauty of form and spines; for instance, *Echinocactus Sileri*, Whipplei, *viridescens*, &c. I think one of the handsomest is *E. Ottonis*; the flower also is splendid although not fragrant. *Cereus* are my favourites, especially the night-bloomers. I have a *C. nyciticaulis*, raised from a 3-inch cutting three years ago, that to this date (July 6th) has opened sixteen flowers this season, and has yet twenty-one buds to open. Until this year I kept it growing to one stem in a 6-inch pot, and trained it along the roof of my small greenhouse, where it received plenty of sunlight during winter. It made a growth of 15 feet in two seasons. I have about ten other varieties of night-bloomers, but I find but little variation in the flowers, except as to size and perfume. The true red bloomer, *Cereus Schmidtii*, has not bloomed for me yet, neither has the variety sent to me from Mexico as a red night-bloomer, and of which I do not know the name.

The *Astrophytum myriostigma*, called in Europe "Bonnet d'Evêque," (Bishop's hood) is a very interesting Cactus, being, I believe, the only one without spines. I don't see how *Aloe longiaristata* could ever have been mistaken for it.—A. BLANC (in *American Gardeners' Monthly*).

THE BURTON CONSTABLE NURSERIES.

BUT few people can have any idea that within so short a distance of Hull there are nurseries so extensive and productive as those which have been established by Mr. E. P. Dixon at Burton Constable. About two miles from the Burton Constable station, on the Hull and Hornsea Railway, there are under the most perfect cultivation ten acres of land which are devoted to the rearing and growth principally of forest trees, ornamental trees and shrubs, fruit trees and Roses, and it was a rare treat we had the other day in going over these well-cultivated and productive grounds, which were formerly the kitchen gardens and the sites of the vineries connected with that palatial residence of the Constables, Burton Constable, which is not now occupied by any member of the family. The whole of the land occupied in the ten acres is under the most complete and scientific cultivation by Mr. Dixon, whose fame as a seedsman has extended far beyond the borders even of his native land, for he does a large export trade to America, Australia, and the Continent of Europe in seeds, shrubs, and fruit trees. Burton Constable is not a great seed-raising ground, but still it may indicate the extent and importance of this trade if we state that on our arrival at these famous nurseries we found that there had just been thrashed out about three tons of Turnip seed, which was about to be despatched to those extensive seed warehouses in High Street, Hull, which have previously been described in our columns. As we have said, however, seed-producing is not the object of these nurseries. They are devoted to shrubs and trees of all kinds, and we saw them in all stages of grafting, budding, and striking. There are acres of standard Roses of the very best varieties known, acres of young

fruit trees, some of them only of last year's grafting, and many of these were bearing most profusely. The grounds are well protected from winds; and although at the time of our visit a fresh breeze was blowing its influence was not felt in the nurseries. There are, of course, some extensive vineries, and the vines, which comprise some of the best known varieties, are just now in full bearing, and amongst the pendent bunches we noticed several which must have weighed 4 lbs. or 5 lbs. each. As we passed through those portions of the estate devoted to the rearing of ornamental shrubs we could not help thinking that the Special Parks Committee of the Hull Corporation, who are about shortly to plant the new Western Park, would do well to visit these nurseries, for there they would meet with trees and shrubs of all kinds, which would go far to making the new park one of the most attractive places near the borough, and not only attractive, but to a great extent instructive.

Amongst the ornamental trees and shrubs which we saw may be mentioned *Acer Negundo variegata*, *Cornus siberica*, *Magnolia Soulangiana*, and many examples of *Cupressus Lawsoniana*, *Biota aurea*, &c., also *Picea Nordmanniana*, *Picea nobilis*, &c. There are also many specimens of the *Wellingtonia gigantea*, such as have been from time to time planted by Royal hands at Brantinghamthorpe. Amongst the ornamental shrubs, too, there was one which certainly ought to be more frequently seen in our gardens and parks. We refer to the Golden Elder, which has, as its name implies, a considerable proportion of yellow in its leaves, whilst it produces an abundant white bloom, and set against a dark background is most effective. The flowering shrubs include the *Rhus Cotinus*, *Spiræa* in endless variety, *Ligustrum lucidum*, *Lilacs* in great variety, *Viburnum opulus*, &c.

Amongst the fruit trees there are Grapes, Peaches, Apples, and Pears of the choicest and most prolific varieties, but perhaps the greatest feature of this department is the Raspberries. These are a variety first introduced by Mr. Dixon, and so successful has been with them that his name is known in connection with them wherever such plants will grow. The name he has given to them is the Baumforth Seedling, and for some years now Mr. Dixon has largely exported the canes to America and the continent, and wherever they have been sent they have given the most complete satisfaction. The fruit is larger than any other Raspberry known, it is also unusually firm, and of the very richest flavour. Upwards of 2 tons of fruit have, during the season just closed, been gathered at the Burton Constable Nurseries. There is an immense variety of Conifers, those most effective plants which are now more fully appreciated for their delicate beauty and rich tints than at any previous time. The standard trees for park and avenue planting include the *Acer Schwedlerii*, *Acer pensylvanicum rubrum*, *globosum*, &c., *Limes*, *Elms*, and *Planes*, *Sycamore*, *Birch*, *Beech*, &c. There is also a very large collection of forest trees for cover planting, which are in the best possible condition for autumn planting, whilst the standard and half-standard *Roses* are amongst the best and healthiest we have seen. Any kind of fruit trees may be here obtained, whether standard or trained, and it was a most interesting sight to see the simple, but effective, measures adopted for the training of Apple, Pear, and Peach trees, so that on their removal from the nursery they have the right form for planting against walls or fences. The Burton Constable Nurseries are not the most extensive of Mr. Dixon's grounds, as he has added at least twenty-five acres to his business at Coniston, and it is at this place more particularly that he raises those seeds which have made his name famous all over the world. He has still another department, and that a most attractive one, at Sculcoates, where stove and greenhouse plants are grown in glass houses that cover one acre of land. From this notice it will be seen that Mr. Dixon's business is a most extensive one, and certainly a visit to his several establishments cannot fail to be both interesting and instructive, especially to those who have known the business from its small beginning. It is one that has always been watched over by the master's eye, and managed with that rare skill and tact which has had its reward in the development of what is now the most extensive nursery and seed-growing business in this part of the country.—(*Hull News*.)

THE LATE DROUGHT.—Mr. Robert D. Long has made valuable suggestions concerning the storage of rain water in good time for next year. We have been consulted by many whose gardens, lawns, and parks were in a pitiable condition, in the hope that provisions could be made to impound the excess in rainy seasons. In every district roof or surface water or springs can be stored in abundance during the winter by constructing underground tanks. Pipes with pumps or hydrants and hose are easily fixed and kept in good working order, and may frequently be available for service in the event of an outburst of fire.—MERRYWEATHER AND SONS, 63, Long Acre, W.C.

HARDY FRUIT GARDEN.

Preparations for Planting.—A dripping autumn is good for planting, and the frequent heavy downpour of rain which has been so general

recently has doubtless induced planters to set about the work earlier in the autumn than usual, in order that as many trees as possible may be settled in the soil before winter. Fruit trees are not planted so early as shrubs, but we must now make ready for the work by marking the stations and doing all that is necessary to have the soil in readiness for the trees, so that the planting may be done with dispatch and in the best way when we do set about it. The station for each fruit tree should consist of 72 cubic feet of fertile soil, either resting upon a natural bed of gravel or chalk, or upon an artificial bed of concrete 6 inches deep, or in other words, it must be 6 feet square and 2 feet deep. This station will afford the roots an ample supply of food for three years, and then if the soil around it is poor and thin, it must be deepened and enriched, and if necessary concrete put beneath it; the necessity for the concrete arising from a cold wet subsoil, into which the roots must not penetrate, or barrenness and canker may follow. Let us take, for example, an orchard of pyramids. The stations will be 10 feet apart, so that there will be 4 feet of soil between the stations for treatment in the third autumn after the planting. It is obvious that when concrete is put beneath a station provision must be made for water drainage, and this is done by laying a row of ordinary 2-inch land drain pipes across the middle of the station upon the concrete, pressing the pipes slightly into the concrete before it hardens, continuing the drain from station to station, or else to the nearest soil drain. Excellent concrete is made by mixing one part of fresh slacked lime with six parts of broken stones, enough water being used to impart the consistency of mortar to it. After it is spread evenly over the bottom of the station, it must be left to harden sufficiently to bear the soil being put in upon it. The station soil should consist entirely of sound fertile loam. We are generally supposed to obtain this in the top spit of an old meadow. But do we? No doubt the herbage and roots of the grass afford excellent nutriment for the roots of the fruit tree for a time, but there must also be an ample store of fertility in the soil itself, and we must make sure that it is there, or the growth of the trees will prove weakly and much of our labour be wasted. Let us also see if the soil contains enough gravel or small stones to insure the quick passage of rain water; if not, we can make all safe by a plentiful mixture of coal ashes with the soil. Remember, we cannot be too careful in the preparation of fruit tree stations, for here work well done is literally twice done, and all subsequent lifting of the trees, root-pruning, and ramming hard substances beneath the trees is avoided. Dwarf bush trees may be the same distance apart as pyramids. Standards should be 30 feet apart, wall trees fan-trained or palmette varieties 25 to 30 feet, according to the height of the wall, espaliers about 30 feet. For cordons there must be a trench 3 feet wide and 2 feet deep of prepared soil, the cordons being planted 18 inches apart.

For bush plants, including Gooseberries, Currants, Raspberries, and Blackberries, soil of a good staple, if drained, trenched, and well manured, will answer well, but there are exceptionally poor thin soils where trenches 18 inches deep and 3 feet wide must be made and filled with good soil for each row. We have had to do this, and we found that a liberal mixture of old stable manure and coal ashes with poor soil insured a free strong growth, which was subsequently maintained by an annual surface dressing of stabling or farmyard manure. Black Currants answer best in a deep rich soil, and where this exists naturally no crop is so profitable as this, for in rich soil the bushes become 6 feet high and as much in diameter, only take care to have them without stoms, so that they may form large crowns or stools, from which young growth springs every year to take the place of any decaying branches. In our next note we purpose giving select lists of the best sorts of fruit for small and large gardens.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Lifting and Replanting.*—The Peach season is over, except, of course, the very late varieties, the time having arrived for laying the foundation of another year's success, whilst the soil retains sufficient heat to insure the formation of new roots before the trees go to rest. In order to succeed in the production annually of full crops of first-class fruit, trained trees have a tendency to exhaust the soil, as they present a large area of foliage to the sun, therefore require copious feeding either by means of heavy mulchings or liberal supplies of liquid manure, and as these frequent applications destroy the fibre of the soil, rendering it sour, too much care and attention cannot be devoted to the renovation of the borders. The most suitable soil for a Peach border is sound turfy loam from an old pasture where the soil overlies limestone, lime rubble, and charred garden refuse, in the proportion of a tenth of the lime rubble and a twentieth of the charred refuse, thoroughly incorporated and protected from heavy rains, as it will not do to put the material together in a wet state. Provide ample drains with proper fall and outlet, and the drainage should be 9 to 12 inches deep of clean broken stone, brickbats, or other material, and so arranged that 2 feet depth of soil will raise the border to the proper level. Cover the drainage with a layer of sods closely packed with the grass side downwards. Place the soil upon the sods, and beat it well down to prevent settling, also to cause resistance to the roots, increasing their ramifications and insure a short-jointed sturdy growth. Observe great care in lifting the trees, particularly where they have been left undisturbed for a number of years, as their roots will be thick and the fibres few; but the greatest care must be taken of the fibrous roots, which are of the most value to the next year's crop—indeed, if these suffer the next year's crop will suffer in proportion. If there be any danger of this, partial lifting only must be resorted to; indeed it does not always happen that old trees require complete lifting, as being well managed when young, all roots having a downward tendency will have been cut off or trained in a horizontal direction, and when this the case it will not be necessary to do more than form a

trench at the extremity of the border and work inwards until all the principal roots can be raised and relaid near the surface in the new compost. Sound healthy old trees that have become weak from age and heavy cropping may be renovated by having all the hard surface soil removed and new compost substituted, to which about 20 per cent. of bone dust has been added. The compost should be rough, dry, and free from manure, employing the latter as a mulching only, which will keep the surface moist, draw the active roots upwards, and feed them when the trees are carrying heavy crops of fruit. The autumn, just before the leaves fall, is the best time for lifting, as the trees usually form or push fresh rootlets, and are more or less active during the resting period, and ready to cater for the swelling buds and blossom when those are excited into activity by warmth.

Selecting Trees.—An early selection of young trees that have not made strong growth is a safe course to follow, and what is equally important is to have them lifted carefully with all their fibres, and kept moist until they can be planted in the borders that have been prepared for them. Of early varieties the following are useful—Alexander, Hale's Early, Early Grosse Mignonne, and A Bec are fine; Belle Bance and Violette Hative succeed, and are followed by Royal George, Stirling Castle, Bellegarde, and Barrington, all of which are worth a place in every garden. Of Nectarines, have Hunt's Tawny and Lord Napier for early; Elruge, Violette Hative, Pitmaston Orange, and Pine Apple follow, and then there is the fine late varieties, Albert Victor and Victoria, to finish with. Of course there are many others worth growing, some finer in appearance, but the quality of those named is unimpeachable.

CHERRY HOUSE.—The roof lights having been removed as recommended, with a view to check the tendency that prevails in early-forced trees to start into growth prematurely, the fine rains we have had recently will saturate the borders sufficiently to meet the requirements of the trees; but if the roof lights have not been removed the borders will become dry unless they are watered regularly and liberally, and as it is very important that the roots have moisture, an examination should be made so that their requirements may be promptly attended to. Every care should be taken of the foliage to keep it clean and healthy to the last.

Lifting and Replanting.—If any of the trees have assumed a sickly appearance, seek for the cause at the root. If the soil be found in an unsatisfactory state about the roots, by all means remove it, and at the same time see that the drainage is in perfect order. After this is complete lift the roots to within a few feet of the base of the trees, and replant them at once in fresh compost, turfy loam from, if possible, a limestone formation, adding a sixth of road scrapings. The operation should be performed just before the leaves fall.

Making New Borders.—The base being levelled to its proper fall, drains should be laid 6 feet apart, 3-inch being sufficient for the purpose, and these must fall and open into a main or transverse one which will take the water away. Between and over the pipes in the house, to which the border should be confined, 12 to 15 inches depth of drainage should be provided, broken stones or broken bricks being most suitable, and they must be clean, and covered with a layer of turves grassy side downwards. The border may be 27 to 30 inches deep, and the compost put together firmly if dry. If wet it must not be trodden, and must be allowed to settle before planting. In planting, which should be done early in autumn, or if that be impracticable it is well to defer it until early spring, as the winter is the worst time to move trees. In planting keep the roots not deeper than 9 to 12 inches. As regards variety there is none equal to the Black Tartarian or Circassian and Elton, and they ought, if others are to be associated with them, be given the warmest position in the house. May Duke, Empress Eugénie being an excellent early form of it, and Governor Wood, also are fine Cherries, good forcers. Frogmore Early (Bigarreau) is also worth a place, and Bigarreau Napoleon, grand, but these must be given the coolest positions.

PLANT HOUSES.

Hyacinths.—Where these are required at Christmas a number of bulbs should be potted without delay. The two earliest of all Hyacinths are Homerus single red, and La Tour d'Auvergne double white. The first is worth growing for its earliness, and on this account only, for although bright in colour when it first opens it soon fades. The double white variety has large bulbs of the purest white, and should be grown by all who desire flowers for wiring, for buttonholes and bouquets. This variety also makes a very fine spike. The earliest light blue is Charles Dickens. Five-inch pots are large enough for single bulbs, while two can be well grown in pots 1 inch larger. Four and five bulbs are very effective for decoration when in flower, but these should be placed in 7 and 8-inch pots. One crock only need be placed at the base of the smallest size, and over this a little decayed manure. These bulbs do well in a compost of fibry loam, one-third leaf mould, one-seventh of decayed manure, and a liberal dash of coarse sand. In potting it is wise to place a little sand at the base of each bulb, and leave after potting the uppermost portion of the bulb just exposed. The pots containing the bulbs should be plunged outside, covering them with about 6 inches of ashes for five or six weeks until the pots are filled with roots, when removal indoors is necessary. In order to maintain a long supply of bloom some bulbs should be potted about every three weeks until the middle of November. For purposes of decoration the following are good, cheap, and useful:—Single blue: Charles Dickens, Grand Lilas, Baron Van Tuyl, Argus, Mimosa, Marie, General Havelock, and Grand Vedette. Single Reds: Amy, Fabiola, Gertrude, Macaulay, Madame Hodson, Robert Steiger, and Von Schiller. Blush: Norma, Gigantea, Lord Wellington, and Grandeur

à Merveille. Single Whites: Alba maxima, Alba superbissima, Baroness Van Tuyl, Grand Vedette, Madame Vander Hoop, and Mont Blancs Single Yellows: Duc de Malakoff and Anna Carolina. Doubles: Duke of Wellington, Blocksberg, and the white kind named above.

Tulips.—For early flowering the varieties of Duc Van Thol may be potted at once, placing five bulbs in a 4-inch pot. These dwarf early kinds are more effective in the size pots named than in those of a larger size. The scarlet variety is the only one we consider worth growing, and prefer to wait a few days longer for Canary Bird, yellow, and White Pottebakker than put up the white and yellow varieties of Duc Van Thol. When potted and forced early Tulips generally come into flower very irregularly. The best plan is to place the bulbs about 2 inches apart in pans or boxes and force them into flower in them, lifting out those that produce their flowers to make up good even pots of bloom. This is the only means by which a number of good pots suitable for decoration can be had early in the season. If the bulbs are kept moist after they have been lifted out of the boxes the flowers will last just as long as if established in pots with the whole of their roots attached. For later flowering place the bulbs into 5 and 6-inch pots in the same compost recommended for Hyacinths. Pot the bulbs for succession, reserving the double varieties for late flowering. The following are amongst the cheapest and best for all ordinary purposes, the white variety previously named being one of the very finest for flowering at any season. Single varieties: Chrysolora, Cottage Maid, Joost van Vondel, Keizerskroon, Le Matelas, Vermilion Brilliant, Wouverman, Vander Neer, Rouge Luisante, and Proserpine. Double kinds: La Candeur, Tournesol, yellow, as well as its red and yellow variety; Rex Rubrorum, Duke of York, and Murillo. Parrot Tulips are very useful, showy, and effective for conservatory decoration; Monstre Rouge, Mark Graff, and Perfecta are three good distinct and useful kinds. The Parrot varieties require the same treatment as the others, but should not be forced into bloom, but brought forward steadily under cool airy conditions, or they draw up tall and weakly, and then half their beauty is destroyed.

Polyanthus Narcissus.—The earliest batches of these will be ready for removal from the ashes. Every care must be taken to admit light to them carefully until their foliage has turned green. Pot them at intervals of about one month until the end of December. Four to six bulbs, according to their size, should be placed in each 6 and 7-inch pot. Single bulbs in 3-inch pots are very useful for decoration where effective arrangements are required. The following are amongst the best cheap varieties:—States General, Soliel d'Or, Grand Monarque, Gloriosa, and White Pearl. For the late supply Grand Monarque should be reserved in a position where roots will not start from the base of the bulbs. These, if potted after Christmas and plunged outside in a northern position and grown outside, will yield their useful flowers for cutting and decoration until the end of May. The bulbs can be kept out of the soil much longer than those of Tulips and Hyacinths without injury, and this is an advantage, for they will flower long after the others.

Border Narcissus.—These are really charming when in flower, and should be grown more largely for conservatory decoration than they are. The varieties of Bicolor, such as Empress and Horsfieldii, and Moschatus (albicans) are most serviceable in 5 and 6-inch pots. If only one variety is grown the second named should be selected, for it is undoubtedly the king of Daffodils; it is dwarf, early, and compact, and as beautiful as any variety. These varieties require the same treatment as the Polyanthus varieties, but should be brought into bloom under cool conditions.

THE BEE-KEEPER.

THE STEWARTON HIVE.

THERE is, perhaps, no hive, not even excepting the straw, hive, that has been so abused as the Stewarton; yet for all that it holds its own in every respect, most prominent for beauty in its produce, while, under all circumstances, it cannot be excelled when in the hands of an expert in apiculture.

Instead of the Stewarton being a big indivisible super as is often represented, it is in reality a sectional super, every comb being divisible or of different weights—exactly what is wanted, and suitable for the purses and tastes of the public. Not only was the Stewarton the first divisible hive, but it was the first to carry a section. I observe still hanging in my workshop some all in one piece (except the bars) sectional supers, that I made more than thirty years since for Stewarton hives. Another very important point which must be kept in view is, the fact that to keep the queen out of the supers has perplexed our modern bee-keepers to the utmost, causing them much annoyance and disappointment, to overcome which expense has been incurred in contrivances and inventions, while the Stewarton hive has all these

means within itself. The supers can also be filled alike on any part of its crown.

Then the American idea of reversing the frames for the purpose of filling supers is a part of the Stewarton system, and can be performed to more advantage and with considerable less trouble than with frame hives. To feed back for the purpose of emptying combs is sometimes a necessity; but to lose time, not speaking of the labour in reversing frames, is certainly far from being economical bee-keeping, and bee-keepers should be thankful to your excellent correspondent "Felix" for bringing the question of labour and expense so prominently forward.

When Stewarton hives are properly managed the surplus honey is mostly stored in supers of matchless purity. If it is necessary to reverse frames after being filled with honey, to be emptied by the bees and carried aloft, it proves the system defective and unnatural as well as wasteful both in bee-life and in honey. There is nothing that exercises bees more than feeding, and consequently hastens decay. We are told that it takes 20 lbs. of honey to make 1 lb. of wax. A writer in a contemporary says 9 lbs., neither of which is correct. From comb containing about 50 lbs. of honey, 1 lb. of wax can be obtained; now the half of that is elaborated on the seals, from which half a pound is got, which means a loss of 10 lbs. of honey from every 50 lbs. extracted by the bees from reversed combs, and the waste of bee-life in performing this unnecessary labour is proportionately large. Surely, then, the hive that can be managed without such waste must be the better one.

It seems strange to me that so few bee-keepers and advocates of the frame hive are in possession of the Woodbury compound frame hive, the best frame with its improvements of any yet made. I suppose the cause of its falling into disuse must be unfair criticism. Some time since a very spirited discussion was commenced on the merits and demerits of the Stewarton *versus* frame hives; but a hive-maker, who edited the paper, interposed an opinion in favour of the frame hive at an early stage of the discussion, thus prejudicing the minds of bee-keepers. The advocate of the frame hive, among other unfair remarks, said that a Stewarton super with the screws withdrawn from the bars, when inverted the combs fell in a mess to the floor—the very thing that would occur according to the laws of gravitation in the ideal pet hive or super he advocated. There is no hive so well adapted for bee-keeping in all places, climate, season, or weather as the Stewarton hive. But bee-keepers should dismiss from their minds the idea that it is the hive alone that is the cause of much honey being gathered, but become impressed with the fact that it is the adaptability of the hive to circumstances, and the facility with which it can be managed by the bee-keeper.

I have, without any aid but what Nature provided, made a bee hive, and I could do the same again, and from that rustic hive I could take the greatest quantity of honey and of the finest quality, fit to be placed on the best table in the world. I have been prompted to write the foregoing through "Felix" asking if I could suggest anything which would be to his advantage in the management of a Stewarton hive. The only thing I can add to what he appears to know is, that one trial with either bees or hives is insufficient to test thoroughly unless everything is equal, and this is often not the case with the queen. When a trial is to be made, attempt to have these of one age and breed, and all else corresponding; make accurate notes, and let us know the results, comparing them one with another, and may we through accurate observation make a united effort to bring bee-keeping to a more economical and consistent system.—A LANARKSHIRE BEE-KEEPER.

PROFITABLE BEE-KEEPING.

"A CAMBRIDGESHIRE BEE-KEEPER," page 194, wants to know "by what magic he will insure skeps swarming, and the swarms giving a maiden swarm after giving a crop of surplus

honey before the stock in the frame hive is ready to swarm." I gave all the "magic" required in the article he takes exception to. Mix plenty of stores in beginning of September to last till next June, a dry straw skep, and I would have an entrance large enough for a rat to run through, and let the bees strictly alone till swarming—in fact, hiving the swarms should be all the attention necessary from one year to another besides feeling if heavy enough to winter.

I carefully avoided giving dates for the hives to swarm, as seasons and districts are so variable; but here this year in an apiary of skeps I packed up last September and never meddled with afterwards, the first swarm in the district came off on May 28th, during Cherry bloom, before Apples were in leaf. All first swarms had come off by June 2nd, and this in the face of the fact that no honey was gathered here till May 26th, and only three or four days previous in which pollen was gathered; yet with plenty of stores brood had been reared, and what bees were in the hives had remained at home and not worn themselves old by working abroad, so that when the weather became settled the hives were overcrowded and were obliged to swarm. Double stocks in frame hives strictly let alone were a month later, while stimulative-fed and brood-spread ones began swarming during the best weather in the Clover harvest, making their owners feel quite doubtful of getting much honey.

A few years ago I thought very much like "A Cambridgeshire Bee-keeper," and used to say if I had a skep stock and a few minutes to spare I would transfer it to a frame hive; but with age comes wisdom, and now with over forty frame hives I say, Stocks in skeps and swarms in frames, the sooner the swarms come the better.

I do not care if one man may get 200 lbs. of honey from a frame hive by means of capital, expense, and attention. If I can get 40 lbs. with one-tenth the capital, one-twentieth the expense, and one-hundredth the trouble, I shall be able to show the greatest nett profit. Much of the nonsense taught by the B.B.K.A. will have to be got rid of by others as well as your correspondent, and bee-keeping looked upon as getting honey with the least capital and expense and trouble, instead of as a feat to get the largest amount of honey from one hive regardless of cost and trouble. How much do you profit a cottager if, say, you teach him how to get 100 lbs. of honey at an expenditure of 100 hours time in the various items necessary if his time is worth 6d. per hour, and then tell him he must be content with 3d. to 6d. per lb. for it? And yet the B.B.K.A. when asked to fix a value on the time spent in the Bligh competition to show the cottagers that they could make more per hour for their time spent on bees than growing Cabbages, the climax was reached by declaring they put no value on a bee-keeper's time, treating it as play time, and asking if we ought to want paying for amusing ourselves. I think it is on these lines they consider we ought to be satisfied with 3d. per lb. for our honey.

A successful competitor in the last Bligh competition wrote me at its close that he was going back to black bees and skeps, if not the sulphur pit. Of course, I thought at the time he was either joking or a little "off," but I now see from observation and experience that for the capital, skill, and time employed the old cottage skep system with the sulphur pit will yield a much greater profit than the modern frame system. In one cottage I visited on August 13th I found four skep stocks had increased into seventeen, and though covered with Rhubarb leaves were quite dry, and all but three heavy enough to winter, most being upwards of 30 lbs. weight. The weather, bear in mind, has been very bad since the beginning of July, the Heather harvest also being a complete failure. I seriously question if the same amount of honey and wax could have been got from four bar-frame stocks. In another apiary twenty miles off three stocks had increased to ten, and only two were too light for wintering. These last were within two miles of the Heather, and had the yield from this source been only moderate each hive would have averaged 60 lbs. weight, as they were crowded with bees. These are only fair examples of what a cottage skep apiary will do when hives with young queens and heavy enough to last till June are selected for stocks. In conclusion, I repeat the point to aim at in bee-keeping is not getting the largest amount of honey per hive, but rather obtaining it with the least capital, labour, and expense, and I believe this can only be by means of skep stocks and very cheap frame hives to put the swarms in.—A HALLAMSHIRE BEE-KEEPER.

DRIVEN BEES IN A FRAME HIVE.

I BOUGHT a bar-frame hive of bees three weeks ago; would you give me your advice as to what quantity of food the bees will want through

the winter? They were driven from two straw skeps and united. The weight of bees alone was 8 lbs., and I am told there was about 35,000 bees in the hive. The food they have at present is in seven bars, each 13½ inches long and about 8½ inches deep. Will there be enough food for the winter? What quantity of vinegar and salt is used with sugar and water when making food? and how long is it to boil? Should they be covered now for the winter, or ought I to wait till the end of this month? Should the dummy board at the back of the bars fit close to the bottom of the hive or not, as my board is about a quarter of an inch from the bottom, and very often the bees are out in the back part of the hive? If you will give me your advice on the above I shall feel thankful.—R. C.

[There is no way of determining the number of bees in a swarm by either weight or bulk. The number that would weigh 8 lbs. when full of honey would weigh very much less when empty. About two pints or, more bees, Scotch measure, will make a good stock to stand the winter, if it has not less than 25 lbs. of honey in store; but by the end of April if breeding has been going on briskly previously, it may then have to be fed again, unless honey is plentiful. If the frames are well filled and sealed, each should contain about 6 lbs. You had better give them at least four frames, if not more. Bees always do better in spring with plenty of food in the hive. Neither vinegar nor salt is necessary to be put amongst syrup. Boil one minute, and keep it stirring till all the sugar is dissolved. The quantity of water required for sugar depends on its quality. Cane sugar (proper) put into any vessel, then soft water poured on it until the water stands an inch or more above the sugar, is about the right thing, but rather keep it a little thin than too thick. Hives should always have their coverings. There should be no difference in them during summer or winter. Dividing boards not reaching the bottom of the hive cause a continual current of air to be passing amongst the bees, and has the contrary effect upon the health of the hive than what it was intended for. You will find your bees more healthy and more easily managed if you have the frames at right angles to the entrance.]

TRADE CATALOGUES RECEIVED.

Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Seed Corn for 1885-6 (illustrated).*

Sutton & Sons, Reading.—*Bulb Catalogue for 1885 (illustrated).*

L. Delaville, 2, Quai de la Mégisserie, Paris.—*Catalogue of Bulbs.*

Michael Rains & Co., 34, Mansell Street, Whitechapel.—*Wholesale Catalogue of Bulbs.*

Charles Turner, Slough.—*Catalogue of Roses, Fruit Trees, and Bulbs.*

James Yates, Stockport.—*Illustrated List of Bulbs.*

Isaac Davies & Son, Ormskirk, Lancashire.—*Catalogue of Rhododendrons and Azaleas.*

of lime fresh from the kiln and place them in water, stirring well, then allowing the lime to settle and the water become clear. If there is any sediment at the bottom of the vessel the water will be as strong as you can make it, and perfectly safe. About a pound of lime will suffice for ten gallons of water. It is best to apply it during mild showery weather, when the worms are near the surface. If there is no sediment at the bottom of the vessel the lime water will not be strong enough. An ounce of corrosive sublimate dissolved in a little boiling water, then mixed with forty gallons of clear water and applied through a rose, has also been found to expel worms from lawns.

Peaches and Tomatoes—Malt Dust (*Vectis*).—If your house is well furnished with Peach trees in a good bearing state we should hesitate in making the change you suggest. If you have not had experience in growing fruit trees in pots you might not succeed so well as you anticipate. With ordinary care no harm would ensue by cutting off the few roots to which you allude, but we do not advise the change. There is no better method of growing fruit trees in pots than that described by Mr. Rivers in his book, and recently by Mr. Hawkins in this Journal. We have seen excellent crops of Tomatoes grown in pots in Peach houses. Malt dust resembles brownish sawdust. It is not the dried growths of the Barley produced in malting, but the refuse that passes through the perforated floor to the fire below, and thus becomes carbonised. It is an excellent manure for various plants and crops.

Damping a Vinery—Placing Pears in a Vinery—Cutting off Strawberry Leaves (*F. J.*).—The vinery should be kept dry, not damping the floor, as the atmosphere will be quite moist enough for the Grapes; indeed the difficulty in a house where fire heat is only given to keep out frost will be to have it dry enough. A little ventilation at all times so as to promote a circulation will be desirable, as a stagnant atmosphere is not favourable to the keeping of Grapes, and hinders the ripening of the wood. Pears should not be placed on shelves in a vinery, but in a cool place, and kept in the dark rather than light, until they become ripe, or until a day or two before they are fit for table, when light improves them considerably. It is not good practice to cut away the head and leaves of Strawberries, as they are essential to the development of the crowns.

Primula and Cyclamen Leaves Spotted (*R. C. W.*).—The leaves are attacked by a fungus, which is much fostered by a close badly ventilated atmosphere, and is also encouraged by a too rich soil. We should try the effect of some artificial manure as a surface dressing, so as to stimulate root-action, and maintain a genial condition of the atmosphere with a rather free circulation of air. The plants should be syringed with a solution of sulphide of potassium, in the first instance at the rate of half an ounce to a gallon of water; but the chief thing is to get them into better health, and then if the leaves are still spotted, apply the sulphide of potassium at 1 oz. to the gallon of water. Otherwise do not syringe the foliage, and keep the plants near to the glass.

Mildew on Roses (*A. G. F.*).—Mildew is usually the most prevalent when the roots of Roses are in poor and too dry soil, and the position is more or less low and sheltered. Syringing the plants with water in which 2 ozs. of soft soap is dissolved in each gallon, and while still wet dusting the affected parts with sulphur, is a good remedy; but at this season the ends of the worst shoots may be cut off and burned. Copious applications of liquid manure to the roots would almost certainly be beneficial. Not knowing the nature of the soil we are unable to say whether lime would improve it or not; if it is needed we should apply it in the spring.

Bluebottle Flies (*B. G.*).—The flies you sent with the Vine leaves are those named above and are plentiful in late summer in most gardens, frequenting walls, vineries, and other places where there is warmth and decaying or cracked fruit. They are best trapped; some soda-water or similar bottles being about half-filled with sweetened beer and suspended by a piece of string or wire tied round the neck in places where they frequent. The flies will enter and be drowned. The bottles require to be emptied when they get full and the contents renewed. The most likely cause of the Grapes on the Muscat Hamhurg Vine shanking is the roots being deep in a cold badly drained border, the remedy for which is lifting, removing the old soil, and rectifying the drainage, laying in the roots in fresh soil nearer the surface, which should be done so soon as the leaves give indications of falling.

Passiflora not Flowering (*George Murray*).—We are unable to account for the Passionflower casting its buds, but it mostly arises from the plant being over-vigorous, the wood not ripening sufficiently. This is common when the plants are grown in a dark position and do not receive sufficient air and light for the solidification of the growth. Try root-pruning or confining the roots, which will give short-jointed wood, and probably the plant will then expand its flowers. Hybrid Passifloras are not by any means unusual, but we do not know of any between the varieties to which you allude.

Retinospora ericoides (*G. S.*).—The plant is not a Juniper, but bears the name given above. It is easily propagated by cuttings, which strike readily if inserted in sandy soil under handlights out of doors, and if given a good watering after insertion they will not require any farther attention until spring. It will, however, be necessary to cover the frames with mats and similar material in severe weather. Cuttings can also be inserted in pots and placed in a house where the temperature does not fall below 40°, and some plunge the pots in slight bottom heat, but in this case much more attention is needed than for those out of doors. It is not too late to commence propagating the plants this season, and you should have no difficulty in obtaining a good stock of young plants for next year.

Stopping Bouvardias (*E. H.*).—You may now pinch out the flower trusses that are showing, the present time being quite late enough to have them flower at Christmas as they do not come on so quickly at this time of year as in summer. If you cannot command a higher temperature than 50° by artificial means it would be best to leave the plants as they are and keep them back until early December, when they may be brought into flower by placing in heat. 2, The Narcissus and Liliums may be planted between the pots of Chrysanthemums. The soil will not become too moist for the bulbs if you confine the application of water and liquid manure to the pots. We presume the Chrysanthemums will be moved indoors for flowering in the

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Insects on Chrysanthemums (*S. Jones*).—The insects shall be carefully examined, and a fuller reply given in a future issue; in the meantime destroy them, as they are undoubtedly injurious.

Tree Carnations (*Inquirer*).—These plants require a very light house, and when placed in position in the autumn the same temperature and ventilation will be suitable for them in which Pelargoniums would be kept steadily growing, or about 45° at night, with a free circulation of air, a close atmosphere being very prejudicial. When first housed free ventilation is of more importance than maintaining any particular degree of temperature.

Exhibiting Roses (*Rosarian*).—We fail to see that any benefit would result by publishing your letter. It is well known there are "open" classes at local shows, and a local exhibitor has a perfect right to choose those in which he can stage the best, provided he does not do so in contravention of the regulations. This is indeed what "great" exhibitors do. If other persons in the district have equalled or surpassed the exhibitor to whom you allude, we will readily record any facts with which you may favour us on the subject.

Worms on Lawns (*G. R.*).—There is no simpler remedy for expelling worms from lawns and borders than clear lime water. Get some lumps

course of a week or two, so as soon as the flowers begin to open; the holes from which the pots are taken can then be filled with suitable compost. Cover the bulbs about 4 inches deep.

Outdoor Mushroom Beds (*Earnest Inquirer*).—After a bed has ceased bearing it must be entirely cleared away. Some beds continue productive for more than three months, others do not bear so long. The amount per yard to which you refer is realised in three months by competent growers, often much more, but whether you will succeed in the first attempt or not it is impossible for us to say. Your proposed arrangement of preparing the beds will do very well, and the third bed should be made early, not late in January.

Fruit for Market (*H. S. E.*).—It is next to impossible to name the "best" varieties of fruit without reservation, as some succeed in one district and not in another. The following are generally good:—Pears: Jargonelle, Williams' Bon Chrétien, Louise Bonne de Jersey, Hessel, Fertility, and Doyenné du Comice. Plums: Early Prolific, The Czar, Green Gage, Victoria, Mitchelson's and Kirke's. Apples: Irish Peach, Worcester Pearmain, Cox's Orange Pippin, King of the Pippins, Blenheim Pippins, and Dumbleton's Seedling. Gooseberries: Whinham's Industry and Whitesmith. Red Currants: Ruby Castle (Victoria) and Red Dutch. Black Currants: Black Naples and Lee's Prolific. Raspberries: Carter's Prolific and Baumforth Seedling. Strawberries: Sir Joseph Paxton and Vicomtesse Hericart de Thury.

Enlarging Vinery (*An Old Subscriber*).—We are glad to learn that you continue to enjoy your garden and the Journal that you have read for so many years. It is not easy to determine the best method to adopt in furnishing the additional part of the house; but as the Vines are healthy and well rooted we should hesitate to lay the stems in the soil lest the resulting growth should be too exuberant. The alternative plan would answer, but the horizontal portion of the rod would be of no use for bearing. Probably the best plan would be to again lift the Vines, drawing them to the front of the house. They appear to be in excellent condition for removal, and if the work is done at once, taking particular care that the roots are not dried, syringing the Vines and shading the house afterwards if needed for keeping the foliage fresh, they would commence rooting at once and start into growth next year about as strongly as if they had not been disturbed. By this plan you would lose no portion of the rods for bearing, and a much greater extent of the roof would be covered than by either of your propositions of bending the stems. If you do not remove the Vines, we prefer the plan (No. 2 in your sketch) of not burying the rods.

Pears not Ripening—The Congress (*J. H. W.*).—Many varieties of late Pears refuse to ripen when the roots of the trees are in cold clayey soil. The only remedy is to proceed as you have done with the Jargonelles, mulching heavily to keep the soil moist near the surface in the summer. If it gets dry there the roots will certainly strike down into the subsoil, no matter how congenial it may be. If you place them in good soil near the surface, and keep them there in the manner suggested, we have no doubt the fruit will ripen. All you can do to induce the Pears to ripen is to place them in a close box in a very warm house. A closely observant person having a fair knowledge of Pears may determine the names of several varieties by an attentive examination of their characters with those described in the "Fruit Manual." You, with others who are interested in Pears, should endeavour to attend the ensuing Pear Congress at South Kensington; and we should be very glad if gardeners could be encouraged by their employers to visit a collection that will be highly instructive, as a long time may elapse before a similar opportunity may occur again for gaining knowledge of the nature indicated.

Ash Tree Roots in Vine Border (*A Single-handed Grower*).—Provided you were careful to remove all the roots of the Ash, or the woody portions of them, there is no reason why the Vine roots should not thrive in the border. The Ash roots would no doubt have greatly impoverished the soil, which you will in some measure have enriched by working in "a quantity of good stable manure," which may be advisable in your case, though not generally so, as the manure for Vine borders is best given at the surface as a mulching. If, however, the roots of the Ash have not been removed, there is danger of fungus being produced and passing from the decaying Ash roots to those of the Vines. You would be acting wisely in removing the surface soil down to the roots in the inside border, picking the soil from amongst the roots without injuring them, substituting good turfy loam, to which has been added about 12 per cent. of bone meal or dust. Do not mix any manure with the soil, but mulch the surface with 3 inches thickness of short fresh stable manure. It will not be safe to lift the whole of the roots, but a portion may be lifted without prejudice to next year's crop, though it must be done with care, and as soon as the wood becomes ripe, to lift the roots confined to the inside border would certainly tell disastrously upon next year's crop.

The Nutmeg Tree (*J. C.*).—The Nutmeg Tree (*Myristica moschata*) is a native of the Moluccas and neighbouring islands, but is now cultivated in Java, Sumatra, Penang, the Isle of Bourbon, Mauritius, and other parts of the East, and in Cayenne, Martinique, and some of the West India islands. It attains the height of 30 feet, with a straight stem and a branching head. The juice is acrid, viscid, and abundant; of a red colour, and dyes linen a permanent colour. The leaves are oblong-oval, glossy on the upper surface, and whitish beneath, and with an aromatic taste. The flowers are male and female on different trees, insignificant, and of a yellowish colour. The fruit is round or oval, about the size of a small Peach, with a smooth surface, green at first, but becoming yellow when ripe. The external covering, which may be called a husk, is thick and fleshy, containing an austere, astringent juice; becoming dry by maturity, it opens in two valves, and discovers the nut covered with its aril, or mace, which is of a beautiful blood-red colour; beneath the mace is a brown shining shell, containing the kernel or nutmeg. A plantation of Nutmeg trees is always made from seed, and it is not till the eighth or ninth year that the trees produce flowers. The sexes being on different trees, after the plants are two years old they are all headed down and grafted with scions taken from the female tree, reserving only one male stock for fecundation. The natives of the Moluccas gather the fruit by hand, strip off and reject the pulpy husk, detach the mace carefully and expose it to the sun, which soon changes its beautiful

blood-red colour to a light brown; it is then sprinkled with sea water to render it flexible and preserve it. The nuts are first sun-dried and then smoked, until the kernels rattle against the shell. This shell being removed the kernels are dipped twice or thrice in lime water, laid in heaps for two or three days, wiped, and packed in bales or barrels. There are two varieties of the Nutmeg, distinguished as the "green" and the "royal;" the royal is larger, and produces mace longer than the nut, while that of the green extends only half way down.

Names of Fruits (*T. C.*).—1, Souvenir du Congrès; 2, Jargonelle; 3, Windsor; 4 and 5, not known, too unripe; 6, Winter Nelis. (*County Dublin Subscriber*).—1, Diamond Plum; 2, Prince of Wales; 3, not known; 4, Windsor Pear; 5, Beurré d'Amanlis; 6, not known, too unripe. (*H. Hutchinson*).—1, Peach; 2, Hampden's Bergamot. (*H. Hewat Craw*).—White Astrachan. (*J. K.*).—Plums, red one Victoria, the three yellow ones Jefferson. You will find the history and descriptions of those you mention in new edition of the "Fruit Manual." (*Lieut.-Col. Ward*).—The Apple is quite new to us, and is one you would do well to preserve. It is very beautiful, but we cannot form an opinion of its merit, as it is long past its best and is quite mealy. If it is of good flavour, its appearance and earliness are great accompanying recommendations to it. (*T. W. Sanders*).—Jersey Gratioli. (*X. Loughdale*).—1 is undoubtedly Dutch Codlin. The Royal Codlin is quite distinct, and if you refer to the new edition of the "Fruit Manual" you will there find it described; 3 is Court Pendu Plat. Your specimens of Royal Codlin are certainly small. (*George Picker*).—1, White Doyenné; 2, Fondante d'Automne; 3, Van Mons Leon Leclerc; 4, Durondeau; 5, Duchesse de Bordeaux; 6, Beurré Sterckmans. (*Sandbeck Park*).—Spanish Warden.

Names of Plants.—We only undertake to name species of plants, nor varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. O.*).—1, Clematis tubulosa; 2, not recognisable; 3, Selaginella Martensi variegata; 4, S. caulescens; 5, Polypodium aureum; 6, Davallia canariensis; (*W. A. M.*).—1, Selaginella Kraussiana; 2, Ceanothus divaricatus; 3, Adiantum concinnum; 4, Selaginella Wildenovi. (*A Young Gardener*).—1, Asplenium formosum; 2, Polypodium pectinatum; 3, Polystichum aculeatum; 4, Dracæna indivisa; 5, Viburnum montanum. (*A. S., Bedale*).—1, Probably the variety of Hop is the Coldgate; 2, Viburnum montanum; 3, Lychnis diurna flore pleno; 4, Campanula Trachelium.

Unfilled Sections (*A. G. F.*).—You may keep the unfilled supers and place them on the hive next year at the time you propose—that is early in the summer, when blossom is abundant and honey plentiful. If your hive is not heavy now the bees should be fed for the winter.

THE CLERGYMAN'S FARM.

(Continued from page 242.)

ANIMALS of the farm are generally spoken of as live stock, even poultry being included by this comprehensive term. For our small farm of 80 acres or less, the number of animals required cannot be large. This, however, is a matter entirely dependent upon the size of the family. For example, the dairy may consist of two or three cows, or it

may require seven or eight if there is a large family of children, and in a calculation of numbers, failures of cows must be taken into account. We cannot reckon upon having an unfailing supply of milk from a given number of cows, but must always allow a fair margin for shallow milkers, poor milk, barrenness, and sickness. There is no better plan than having one or two heifers to calve in spring, for they always command a ready sale, and can easily be sold should there be no failure among the old cows. If there is, how gladly do we take our best heifer into the herd and so prevent any lapse in our supply of milk. It is no light matter to be so pressed for milk as to be obliged to purchase a cow, for who will part with a really good cow at a reasonable price? It is true enough that plenty of cows are to be had at every cattle fair, but few, if any of them, are worth having. In making a calculation of the number of cows required, we may take the daily yield of milk of an ordinary herd at an average of 10 quarts per head. If Channel Island cows are had, the per-centage of cream will be large, as much as 25 per cent. having been obtained from the milk of Jerseys; but it is seldom that we obtain such results from other breeds. Yet we have had very rich milk from the hardy little Kerry cows.

Of the general care of cows we may notice briefly the most important points. At the present time of year they should be gradually withdrawn from open pastures, being always taken into the yard at night, where there should be plenty of soft dry litter, both in the open yard and in the lodges. Delicate Jersey cows should be shut into close lodges at night from the present time until they are able to lie out again at night next summer. Nothing must be left to chance, or some so-called accident may cost us dear; illness or death among cows not unfrequently arising from some apparently trivial cause. Do not let cows eat walnut leaves as they fall in autumn, or an unpleasant flavour will be imparted to both milk and butter. Care must be taken at all seasons of the year that they have sweet and wholesome food. We never give them turnips or linseed cake, the dietary after they are taken off the grass into the yards for winter consisting principally of the best meadow hay, with bran, Carrots, Cabbages, Mangolds, and silage. As spring draws nigh they have Thousand-headed Kale, and then comes the early cut of Rye. Weak and delicate cows may require a few crushed Oats, but strong healthy cows do not want anything more than the simple fare enumerated. Undoubtedly they do like a change of diet, and it is good for them. Large, yet snug lodges, soft dry litter for bedding, pure water, wholesome food, careful milking, and, above all things, gentle kindly treatment, go far to insure good health and an abundant yield of milk. If a cowman is worth his salt he will be fond of the animals under his charge, and he will probably have certain little mysteries in his treatment of them into which it is unwise to penetrate farther than to assure ourselves that they are harmless.

"Calves thrive faster in May than in March on a given allowance of milk, simply because the weather conditions are more favourable." The truth of this quotation is obvious enough, and we apply the lesson it conveys by taking especial care to keep calves warmly housed in the early months of the year, and to keep them well fed, avoiding the long fasts to which they are subjected under careless, thoughtless management, and which so frequently brings on indigestion and scouring. After weaning, when they are old enough to eat—say in May or June—they should be taken to a lodge opening into a little yard and paddock of good sound pasture, where they can have green food, exercise, shelter, warmth, and be subjected to no fright or harsh treatment from older animals. Bull calves and inferior cow calves should be fattened and sold for veal, as that is the most profitable way to dispose of them, a prime fat calf being worth almost as much as a yearling.

Of pigs it is desirable that there should always be a certain quantity upon the farm, so that skim milk, butter

milk, house wash, refuse vegetables, and roots may all be turned to account. There should always be a regular supply of home-cured hams and bacon forthcoming from the farm, for swine are unclean animals, eating such foul garbage if they can get it, that it is unpleasant to have to contemplate the possibility of having to purchase bacon or pork. Sheep can hardly be required here, except a few old ewes be purchased in August for folding on second growths of Clover, with corn and cake, being subsequently passed on to the butcher.

Poultry of all sorts should be kept for a supply of chickens, turkeys, geese, ducks, and pigeons, as well as of eggs. Good management tells in this matter as in others, and with it there can be no question about poultry keeping being profitable. Perhaps the most vexatious matter in connection with poultry keeping is the having no eggs in winter, and yet we have only to save enough early poults to have an ample supply.

WORK ON THE HOME FARM.

Wet weather has caused much sprouting among late Barley that was mown and left in the swathe, and the grain is spoiled for malting. We shall turn it to account for home consumption, either whole or ground with other corn for sheep and pigs. Grass and root crops have thriven, and our prospects of autumn and winter food are much improved. Harvest is now over on all our farms with the exception of some Rivett's Wheat sown late on heavy land, and we are now doing our best to get the land clean and to sow green crops and winter corn. We have done our best to plough in as much White Mustard for manure as we could, but it was only the early sowings of Mustard that were really successful, later ones having suffered from drought. We got about half a crop to plough in of sowings made in May, and shall have to add a little artificial manure. Glad indeed are we to find more and more attention being given to this important matter of ploughing-in green crops, which, weight for weight, are almost equal to farmyard manure. We are now ordering our autumn supply of artificial manure to give half dressings to Wheat and Oats, the quantity per acre being a quarter of a hundredweight of nitrate of potash, three-quarters of a hundredweight of nitrate of soda, quarter of a hundredweight of steamed bone flour, quarter of a hundredweight of superphosphate, quarter of a hundredweight of coprolite, and the other half dressing will be applied in February when we put artificial manure upon the grass. The manure is now applied as a surface dressing by hand, broadcast, after the drilling-in of the seed, and before the harrows are passed over the land. It soon dissolves in the moist soil, which thus becomes charged with fertility for the roots of the young corn plants. Do not let the idea that there is some risk of loss of nitrogen from the soil in winter prevent you from the application of artificial manure in autumn. Depend upon it, if we are to have good corn crops the soil must be stored with a reasonable amount of fertility, so that from the germination of the seed there may be an ample provision of food for the plants. We have put this to the proof year after year, and the result has invariably been so successful that we can now be positive in our assertions. Lamentable is the ignorance of farmers generally of agricultural chemistry. "Muck," or farmyard manure is still in full force, notwithstanding the heavy outlay in its manufacture. When will dung mixers and carting of manure be a thing of the past? There is still so much blind faith in bulk. Something that is substantial is what appeals to and lays hold of the mind ignorant of the laws which govern these things. We much fear that the ordinary farmer will for some time to come continue to solemnly cart his half-decayed litter saturated with moisture in the blind faith that what was good for his forefathers must be equally good for him.

REMARKS.

13th.—Fine and pleasant all day.
 14th.—Overcast with drizzles early; fine afternoon.
 15th.—Fine bright morning.
 16th.—Overcast early; fair day; rain in evening and night.
 17th.—Very wet early; rain till 10 A.M.; fine afternoon.
 18th.—Fair morning; fine bright afternoon and evening.
 19th.—Wet morning; fair after.
 Rather warmer and much damper.—G. J. SYMONS.

SEPTEMBER IN THE FLOWER GARDEN.

THE welcome showers of the past few weeks have seemed to rouse up many of the occupants of the beds and borders, and caused them to burst into blossom again. Shrubs and the hitherto scorched lawns are also looking much the better for these genial rains. Perhaps Kent and Sussex have suffered more from the effects of the late trying drought than any other county, in consequence of the gravelly and chalky subsoils. Particularly noticeable were the effects of the drought on the shrubs, trees, plants, and grass at and around Goodwood a week or ten days ago. There the grass was quite brown, and shrubs were dying for want of moisture. No rain had fallen since the first week in July. The upper stratum of soil is very shallow there, the chalk cropping up to the surface. Happily it was not quite so serious in this district, although it was very difficult to keep the occupants of our shrubberies, borders, and beds supplied with the needful moisture. Powerful hydrants and a good hose, intelligently used, proved our best friends through the trying ordeal, and if every garden was similarly well provided, the saving in labour, besides other advantages, would soon pay for the outlay involved.

Turning to the plants used in the embellishment of the garden, there has not been much cause for complaint with regard to abundance of flowers on the hardy plants, also on Pelargoniums and other flowering bedding plants. Pelargoniums have been unquestionably good this season, the plants blooming very freely and retaining a more sturdy, compact habit of growth than is usual with them in damp seasons; and even now, drawing towards the end of September, the plants are all that could be desired. Lobelias are still flowering freely. Cannell's Swanley Blue, which we have grown for the first time this season, was one of the prettiest soft, delicately coloured blue Lobelias we have seen. It is compact in habit and exceedingly floriferous. The varieties known as Emperor William and Brighton No. 1 are also very good. For growing in masses, in the mixed border or on ledges of rockwork, we prefer grandiflora and speciosa raised from seed early in the season. In taking up these plants for store purposes, many fail to keep them during the winter through neglecting a very simple precaution, which is the removal of the flowers and seed vessels by means of a pair of shears about a fortnight before the plants are lifted. By cutting off the seed vessels the plants are induced to make a little growth before their roots are disturbed.

There are so many means employed now in the decoration of the flower garden, some preferring carpet and geometrical bedding generally; others hardy plants in many different forms, from the complete collection down to the select and mixed styles. Here we give preference to the two latter styles, and we have no reason to be dissatisfied therewith, as from early spring until now (September 22nd), by judicious selection and planting, we have had a constant supply of beautiful blooms, and this will continue more or less until far into November. We have no wish to despise carpet and

geometrical bedding where skilfully and tastefully carried out, as at Hampton Court, and many private gardens too, but these styles of bedding have been overdone, consequently there is an almost endless repetition and sameness. A due proportion of these styles should exist in suitable situations, as, for instance, in proximity to the mansion and along terraces; but nothing looks more incongruous than borders with beautiful backgrounds of noble trees and shrubs filled with lines of yellow Calceolarias, flaming Pelargoniums and Pyrethrums. Far more interesting and far more beautiful would these borders be were they tastefully filled with hardy plants. Delphiniums, hardy Lilies, Pentstemons, Campanulas, and a host of similarly beautiful hardy flowers, would certainly be in better harmony with trees and shrubs than the formal rows of Pelargoniums and Calceolarias.

It is surprising to what extent a garden of small dimensions may be made beautiful by the exercise of intelligence and good taste. It is not the thousands of plants employed, but the way in which they are selected and disposed, that makes the most effective display. We make trees and shrubs play an important part in combination with hardy flowers in the decoration of the flower garden—that is to say, no flowering plants are placed in any part except in combination with trees and shrubs. Every border of hardy flowering plants has a suitable background of trees and shrubs, and these are planted in such a form as to create suitable nooks and crannies for the growth of valuable Lilies and other choice hardy plants. Thus, in one part we have an irregularly formed bed of Rhododendrons and Ghent Azaleas, the latter planted amongst the former, and around the margin is a border varying in width from 2 to 8 feet. At the back of one of the widest of these curves is a group of Hollyhocks; a little on the right a strong group of Chrysanthemum maximum; on the left a group of Delphiniums; standing out boldly is a group of Liliun candidum, double purple and white Rockets, Delphinium cashmerianum, Polemonium Richardsoni, Helianthemum pumilum, Campanulas, Gladiolus, Tigridias, and other hardy plants, whilst the foreground is filled with masses of Zinnias, Stocks, Asters, Petunias, Salpiglossis, Coreopsis, Gilias, Godetias, Alyssums, Virginian Stocks, Marigolds, Verbenas, &c. In another nook will be a fine well-established group of Liliun auratum in the background, with single Dahlias, Pentstemons, Helianthemums, Liliun aurantiacum, Rudbeckia Newmanni, and so on. Another group will have a Portugal Laurel, Weigelas, Berberis Darwini, Aucubas, and Conifers for a background, with groups of Lilies, single Dahlias, Lobelia cardinalis, Pentstemons, Foxgloves, hardy Fuchsias, and Hibiscus, Gladiolus, Carnations, with Stocks, Asters, and other annuals in the foreground. Immense slopes thrown up to hide unsightly objects have their summits crowned with now lofty trees of Poplars, Cedrus Deodara, Cupressus Lawsoniana, double Hawthorns, Lilacs, Aucubas, and lower down choice Rhododendrons and Azaleas, with Liliun croceum, Solomon's Seal, Anemone japonica and Honorine Jobert, patches of Helleborus niger, common Primroses, and Lily of the Valley, growing under their shade; whilst here and there the margins boldly develop into large borders filled with the choicest Roses, carpeted with Mignonette in summer and Primroses in winter and spring. Similarly planted is every shrubbery border, either with Roses, hardy herbaceous plants, or annuals. Bold rockeries too are formed for alpine plants. These are a few examples of what can be done by means of hardy plants alone.

Respecting the hardy annuals and biennials in bloom at the present time, they are giving us the fullest satisfaction possible, a great number of them being capable of furnishing blooms for some time yet. Particularly showy are large groups of Cannell's lemon and orange African Marigolds, bearing immense flowers, and not less so are groups of Webb's brilliant strain of Petunias, which have been blooming freely since June, and seem likely to continue for some time yet. Old worn-out birch garden-brooms are turned to account by

using its wood to support the Petunias from trailing along the ground. Godetia Carter's Spotted Carpet is a charming dwarf free-flowering variety of this lovely annual, and is still blooming freely. Verbenas make fine border plants when planted in irregular masses near the margin of the border, and not pegged down, but allowed to grow freely. We have a beautiful display of seedling plants raised from Messrs. Webb's Pride of Kinver strain. Most lovely, too, are a mixed strain of Coreopsis. These flower and grow just as freely on a north as a south border; also they are not in the least particular as to growing in the shade. Zinnias (single and double), French Marigolds (Carter's tall and dwarf striped), and Tagetes pumila are still the life of the garden, conspicuous by the brilliancy of their flowers. So also are the Dianthus Eastern Queen and Crimson Belle, Heddewigii, and the Indian Pink. These, although biennials, should be retained for one year only, as they succeed much better if raised annually from seed. The many varieties of Emperor and German Stocks are still flowering freely, as also are the Asters. The Pæony and German quilled, Emperor and Victoria, are fine. Sutton's Miniature is a pretty dwarf strain, and so is Carter's new dwarf crimson bedding Aster. We grew our seedlings in a cool frame this season, and we found this plan much better than sowing them in heat. The varieties of Phlox Drummondii are especially showy, the variety known as coccinea being brilliant. *Lilium grandiflorum rubrum* is another lovely annual still in bloom. The red, white, and crimson varieties of the Valerian are very showy. These are but seldom met with except in cottage gardens in the west of England, where large clumps of them are seen in bloom. They are easily raised from seed.

Hardy herbaceous plants still continue to do the chief share in decorating the borders. *Rudbeckia Newmanni* is a mass of blooms, its bright yellow florets with dark centre rendering it a very showy plant. *Chrysanthemum maximum* is another capital free-flowering autumnal plant, together with *Pyrethrum uliginosum*, similarly white-flowered. *Lobelia cardinalis* is a grand autumnal bloomer, as also is *L. syphilitica*, with flowers of various hues. *Campanula pyramidalis* is a noble plant. Its beautiful spikes of blue flowers are charming. Of the many beautiful autumnal flowering plants few can surpass *Senecio pulcher*. This will last in bloom until frost sets in. *Pentstemons* are most useful and showy plants. Our seedling plants are just commencing to flower. These will follow the older plants and keep up a succession of bloom. We have a few *Delphiniums* still in flower, but these are seedling plants of last autumn, planted in the borders in May, and which did not commence flowering until the old-established plants had ceased doing so. It is evident, therefore, that if frequent sowings were made it would be possible to keep up a succession of blooms for a long time. We have upwards of 300 seedlings just pricked out in a store bed in readiness for transplanting into the borders next spring. Herbaceous *Phloxes* are still flowering freely. The Queen, a lovely white, bearing immense spikes, is a most effective late-flowering variety, as also is the Countess of Breadalbane, a rosy carmine variety. *Gladiolus brenchleyensis* and *gandavensis* are flowering freely. These are noble border flowers, especially where afforded generous treatment and planted in groups of not less than a dozen corms. Hardy *Fuchsias* are splendid plants for growing either in isolated positions or in the mixed border. In the latter position they are most effective for dotting about—one well to the front, another a corner plant, and one in a nook or recess in the borders. In such positions their graceful habit of growth renders them specially suitable for breaking the uniformity of outline in the arrangement of the plants in the border.

We have still a good show of yellow Carnations. This variety originated from seed in the garden here some years ago, and is one of the finest hardy, free-flowering yellow border Carnations we have yet met with. Lovely groups of *Lilium auratum tigrinum* fl. pl. and *lancifolium album* and *rubrum* are still in full bloom. The *L. lancifolium* varieties

are not permanently planted out, but are grown in pots until May, and are then planted. This lovely Lily is not sufficiently hardy to withstand the winter out of doors—at least, such is our experience; hence we lift the bulbs in autumn. The *L. auratum* succeed well with us. We find a somewhat high and well-drained position is the main secret of success in their outdoor culture. We hear that the *auratums* planted among the *Rhododendrons* on the well-drained slopes in the charming grounds of Oldlands by the able gardener, Mr. Luckhurst, a year or so ago, have flowered magnificently this season. Notes on the method adopted by him have appeared from his pen in the last volume of the Journal. Ours are growing in various positions—the summit of rockeries, on rock beds, and in suitable nooks and corners of the borders.

Single Dahlias are grand just now. We have discontinued growing the double varieties, except the Cactus, Constance, and Juarez. These do not bloom at all satisfactorily; therefore we shall not attempt to grow them another season. Of the single type Harlequin, Darkness, Lucifer, White Queen, Walton Ware, Paragon, and lutea grandiflora are grand free-flowering and showy varieties. Sweet Scabious in various colours are also very showy and effective. Hollyhocks are on the wane, but we still have a few good clumps in bloom—seedlings of last autumn. We shall in future grow our stock from seed only, as we find the plants better able to stand the disease than when raised from cuttings, the plants being more robust and healthy. The queen of flowers has still a little of her royal lustre left to grace the closing days of September. That grand Rose, *Souvenir de la Malmaison*, is still bristling with lovely buds and blossoms. With us it is the first to bloom on a warm wall and the last in the borders. *Gloire de Dijon* is still blooming on a standard 12 feet high and on dwarfs in the borders. *La France* and *Baroness Rothschild* have still some queenly looking blooms, and so has *Magna Charta*, *Beauty of Waltham*, *Abel Carrière*, *Miss Hassard*, and *John Hopper*. The fragrant *Mignonette* with which the Rose beds are carpeted is delightful, and compensated for the absence of Roses.

Last and not least are the glowing colours of crimson and gold diffused through the fading green of the dying foliage of deciduous trees and shrubs. How beautiful are the fading leaves of the Ghent Azaleas peeping here and there out of the sombre green of the *Rhododendrons*! The deep crimson, gold, and warm brown diffused through the snowy *Mespilus*, the golden foliage of *Weigela Looymansii aurea*, and beautiful variegation of the *Hollies*—these and many more similar examples of Nature's autumn painting show how necessary it is that skill and taste should go hand in hand in the selection and planting of our shrubberies and woodlands. To the student of Nature there is as much beauty in the contrast and harmony of foliage as in the blending of colour in our bedding, and yet how little do we study this essential point! But enough has been said for the present on the subject of the flower garden in September.—A KENTISH GARDENER.

HOW WE CLEARED OUR VINES OF MEALY BUG.

WHEN I took charge of these gardens in June, 1884, the Vines were infested with mealy bug, and the Grapes, which were a very poor sample, were just beginning to colour. Now there is not one insect of this kind to be found in the vineries. Possibly it may be useful to some of the readers of our Journal if I describe how we managed to banish the pest, as it is impossible to grow good Grapes where it is present, and now is the best time to commence operations if all the fruit is cut.

Some of the bunches were free from the pest, and a piece of cotton wool tied tightly round the stems kept them clean until they were ripe, when they were all used as quickly as possible, and then we commenced action in earnest. The Vines were rather old, the borders and roots in very bad condition, spurs very long and only about 9 inches apart on each side of the rods. The laterals after one stopping had grown into a thicket; half of the spurs were sawn off, leaving the cleanest and best, and the

shoots shortened, leaving about five joints and one joint of the sub-laterals. We then cleared all rubbish out of the house and syringed well with water in which petroleum had been mixed 1 oz. to the gallon and the same quantity of softsoap. This syringing was repeated occasionally until all the leaves had died. The Vines were then pruned rather closely, all crevices in the rods cleaned with a knife, and all loose bark removed. The walls were thoroughly scraped, and, with the woodwork, were syringed with boiling water containing 4 ozs. softsoap to the gallon. The houses were closed and well fumigated with strong brimstone; the walls were whitewashed with hot lime, sulphur, and carbolic acid, all glass and woodwork being painted with petroleum, working it well into the crevices. The Vines were scrubbed twice with hot softsoap water 6 ozs. to the gallon. Some tar was obtained from the gas house and some stiff clay; the latter was thoroughly dried and reduced to a powder and then stirred into the tar, making rather a stiff kind of paint. This was then thoroughly worked all over the Vines with a stiff brush, taking especial care to stop all the holes and crevices in the rods. Four inches depth of soil was taken off the border, and as the outside roots had been all lifted, the inside ones were disturbed as little as possible, some good decayed manure, bones, and fresh turfy loam were put on again, and we thought we might say good-bye to the mealy bug after that.

The Vines were started steadily on January 5th and appeared secure until February 13th, when the leaves were unfolding and the sap in rising had slightly swollen the rods, causing little fissures in the tar-and-clay mixture round the spurs. On examining these a few bugs just hatched were found in two or three places, and it was evident our enemy was not killed. A gallon of warm water was obtained, and into this we put half a pound of softsoap, five wineglasses of petroleum, and five wineglasses of carbolic acid, and then painted all the Vine rods thoroughly, working it well round the spurs, but taking especial care not to touch the young shoots; this was a drop too much for the little white-coated visitors, and not one has survived.

When using the petroleum we were always very careful to keep the mixture well stirred; the carbolic acid used was the common dark brown kind, which can be obtained at 4s. 6d. per gallon, and which we find very useful for many purposes.—W. H. DIVERS, *Ketton Hall*.

ROSES—CONFUSING NOMENCLATURE.

SHAKESPEARE has a great deal to answer for. He rashly suggested that "A Rose by any other name would smell as sweet," and, as if to prove him a prophet, Roses have been given almost every other name conceivable. But the bard said "any other" name, and those who in desperate vindication of his seer-ship have given a Rose the same name as that of one already in existence are likely to be considered, like some other zealots, tiresome.

For instance, we have Comtesse de Paris (E. Verdier, 1864), a pretty enough H.P., though too thin to be of real value, where-upon Levêque, in 1883, sends out another Comtesse de Paris, which in spite of being a first-rate Rose, by some considered better than Countess of Rosebery, is likely to get less notice than it deserves owing to a confusion with a comparatively worthless variety. In the same way Jules Chrétien (Schwartz, 1877), a really good, vigorous, free-flowering, dark H.P., especially as a garden Rose to grow as a standard, makes its appearance to confuse growers who have discarded the indifferent variety of the same name distributed by Damaizin in 1869. It is only by the specification of his earldom that the beautiful but delicate Earl of Beaconsfield (Christy, 1880) escapes nominal identity with Lord Beaconsfield (Schwartz, 1878); while E. Verdier's two seedlings, Madame Prosper Laugier (1875) and Prosper Laugier (1884) run a considerable risk of getting mixed, as do the two Teas Madame Margottin (Guillot, 1866) and Madame Jules Margotten (Levet, 1871).

Sometimes, no doubt, it is only a regrettable coincidence when two Roses appear in the same season with the same name, as when in 1877 Nabonnand, called a pretty light H.P. Madame Anna de Besabrosoff, a name which Gonod simultaneously bestowed upon a dark red seedling from Charles Lefebvre. François Louvat and François Levet, as well as Levet's two Teas, Madame Berard and Madame Bernard, are two pairs of names very liable to confusion, but this may be perhaps best avoided by growing only the first-named of each couple, F. Levet and Madame Bernard being of little value.

Happily many Roses thus afflicted have gone out of cultivation, but Vernet keeps up the complication by this year dis-

tributing Baronne Nathaniel de Rothschild to get mixed with Baron Nathaniel de Rothschild (Levêque, 1883), regardless also of the fact that this makes the sixth Baron(ne) Rothschild sent out. Perhaps the best way to avoid a muddle in this case will be to adopt Mr. George Paul's plan of translating the lady's title at once to Baroness Nathaniel de Rothschild.

The giving of the same name to two Roses that are in different classes is less reprehensible, but still inconvenient, for if anyone wishing for Nabonnand's pretty red Tea Duchess of Edinburgh (1874) should receive instead Dunand's H.P. of that name, probably remarks would be made of the kind that is not usually fully reported, while vituperation would inevitably ensue on the receipt of Nabonnand's Tea Duchesse de Vallombrosa (1879) when Schwartz's beautiful H.P. had been desired. So that it may not be altogether useless to indicate the following chief instances of this malpractice:—

Jules Finger.....	{ H.T. Lacharme, 1879.
	{ T. Madame Ducher, 1879.
Madame Hippolyte Jamain.....	{ T. Guillot, 1869.
	{ H.P. Garçon, 1871.
Duke of Connaught ..	{ H.T. Bennett, 1879.
	{ H.P. Paul & Son, 1876.
Duchess of Connaught ..	{ H.T. Bennett, 1879.
	{ H.P. Noble, 1882
Madame Eugène Verdier ..	{ H.P. E. Verdier, 1878.
	{ T. Levet, 1883.
Princess of Wales ..	{ H.P. Wm. Paul, 1864.
	{ T. Bennett, 1882.
Princess Beatrice ..	{ H.P. Wm. Paul, 1872.
	{ T. Bennett's new Tea.
Henry Bennett ..	{ H.P. Lacharme, 1875.
	{ T. Levet, 1872.
Madame Ducher ..	{ T. Ducher, 1869.
	{ H.P. Levet, 1879.

The last two names may be excused as being but little cultivated. Levet's Madame Ducher, although a fine flower, being such a wretched grower and a victim to mildew.

After so considerable a work as the publication of their illustrated catalogue, the Committee of the National Rose Society will probably be glad to let such matters rest for a time, but when next the question of synonyms is gone into, the authoritative judgment of the Committee on the following very-much-alike Roses, quite apart from their worthiness of inclusion in the catalogue, will be gladly welcomed:—

La Reine, Reine du Midi, Alice Dureau; Duc de Rohan, Mrs. Jowitt; Souvenir de Spa, Comtesse de Camando; Antoine Ducher, Edouard Pynaert, Marie Louise Pernet; Madame Berard, Melanie Soupert; Alfred Colomb, Wilhelm Koelle; Elise Boelle, Madame Noman, Mlle. Bonnaire, Madame O. Kerchove; Madame Maurin, Madame Denis, Adèle Pradel Bougère, Clothilde; Narcisse, Enfant de Lyon.—THETA.

APHIDES AND THE DROUGHT.

I HAVE deferred writing for this Journal some notes on the extraordinary migration of aphides (vulgo "fly" or "blight") that occurred last July, because I was desirous of ascertaining whether in those localities where numbers of these insects were noticed travelling through the air they were subsequently found infesting plants in gardens to an unusual extent. So far as I know up to the present time, such was not the case upon the Hops, and of course upon various cultivated plants there have been aphides during the later summer, but not generally in abundance, but they were very plentiful in many places through the early part of the season undoubtedly. The prompting cause of this migration was, to all appearance, the dryness and comparative coolness of July, owing to which the plants that had afforded food to the aphides failed to yield the needful supply of sap. As a consequence, these insects (at least, certain species), ceased to multiply in the wingless form, and a brood emerged of the winged type, which then set forth to seek fresh provender with questionable success.

For the information of some readers, I may state briefly that it is customary for the insects of this tribe, or the majority of them, to make two yearly migrations—one in the spring, the other in the autumn, the particular date depending upon the weather. It is on these dull, somewhat oppressive days, of which we get several both in spring and autumn, that, from the check given to the flow of sap, the food plants of the aphides no longer furnish abundant food. The unwinged insects no longer appear, the winged emerge, and then follows a migration, when people say, and truly, "there is a blight in the air." An easterly wind has been credited, amongst other mischiefs, with that of bringing aphides, but I do not think facts support this, for I have seen them flying with the wind from every quarter. As a rule, they

prefer to migrate on a day that is rather calm. Still, it may be true that the east wind, by its chilling influences, often produces an effect upon vegetation that sets the aphids hosts adrift. How far they travel in these migrations is a debateable point. The late Mr. Walker, and other observers, state the distances are usually short, but it seems probable, as I will show, that they may go a mile or more, ill-adapted as they seem for flight. In that case, it is likely they move along, not so much by any effort, as by yielding themselves to the force of the breeze.

How far the aphid migration of July last extended over the British Islands I cannot say, doubtless it would be most marked in the counties that suffered greatly from drought. It was noticed by myself in the districts of Middlesex, Essex, Kent, and Surrey; it has been reported from the Midlands, and I trust one result of this article will be the publication of further particulars in reference thereto. This migration was remarkable, not only for the month of its occurrence, but for the long time it lasted (a fortnight, or about that), and the aphides were, contrary to custom, on the wing while a strong wind was blowing upon several days. They came also to us in North Kent from all directions, frequently in such numbers as to be an annoyance to passengers along roads or across fields, sometimes entering the eyes, ears, and mouth. Having to be in London on one of the last days of July, I crossed from the eastern suburbs to the western, and in every street there were aphides wafting about. The most singular scene, however, was on the morning of August 1st, along the High Street, Gravesend, and some of the thoroughfares adjacent. Here every by-passer exhibited them upon his clothes by scores, and along the angles of doorsteps and similar places the insects laid in little green heaps, seemingly driven to the ground by exhaustion.

With regard to these, and some observed near the Kentish shore on previous days, it is a fair conclusion that they must have crossed from Essex, a distance of at least three-fourths of a mile. And a part of those that had thus made their way across the Thames very possibly travelled a mile overland in Kent and Essex, if not more. As to the species, two were conspicuous—a green aphid that I take to be *A. Humuli*, or its variety *Malahab*, an insect occurring not only upon the Hop, but on fruit trees and various Rosaceous plants. The other was a small blackish aphid, in much less numbers. Of its identity I am uncertain, it resembled a species often abundant on aquatic plants. Of these aphid hosts I believe few survived. They either died *en route*, or in reaching new food-plants found them as sapless as those they had left.—J. R. S. C.

TOMATOES.

THIS valuable vegetable is rapidly growing in popularity, and an enormous trade is done throughout England in this article of consumption alone, to the extent of a great many tons annually. We have now such a host of varieties that it is an important question which pay the best, and if growers give their experience in various localities, your readers will be able to judge for themselves which they may prefer for their own growing.

There is now an extensive trial of Tomatoes at Harefield Grove, near Rickmansworth, the residence of George Webster, Esq., where 5500 plants are now fruiting, and have been in bearing for some time, all cultivated under glass, and with the exception of the two early houses no fire heat has been used. In one of the early houses Hathaway's *Excelsior*, planted last September, and in bearing since March, will be discarded to make room for Harefield Grove Red, originally a selection made by Mr. Gough's father many years since from the Old Red, and since carefully selected by Mr. Gough, the manager of the Harefield Grove Gardens, and a fixed character obtained. It is large and handsome, highly corrugated, and of a rich bright colour, of short, sturdy habit and short-jointed, and a prolific cropper, and regarded by Mr. Webster and Mr. Gough as the premier variety of the collection. A long span-roof house has recently been planted with this variety for the winter supply, and the plants are now 2½ to 3 feet high, strong and vigorous and already fruiting, and all have been struck from cuttings.

King Humbert.—This is extensively grown there, and is a favourite, but at present it is of a very sportive character and wants selecting. Mr. Gough intends using cuttings from the true variety, which is oval in shape, of medium size and deep red in colour, fruiting profusely in clusters, and is a handsome ornamental variety of medium height. In a range of frames this variety is planted out and growing in the soil and fruiting abundantly.

Chiswick Red.—A good cropper both in pots and planted out, and is like *King Humbert* in form and habit, but the fruit is far less solid and heavy. In fact it is of a woolly substance, and Mr. Gough does not intend growing *Chiswick Red* again.

Williams' Improved Orange-field.—A very fine prolific variety, not very smooth, but of good size and weighs heavily, of dwarfish habit, and is regarded by Mr. Gough as second best to Harefield Grove Red.

Sutton's Perfection.—A very large handsome and smooth fruit; a

fine late variety and a good cropper, but not so heavily as the Harefield Red or Improved Orange-field, but a good exhibition variety.

Sutton's Maincrop.—This shows some very large fruit, but is not a good bearer under glass. In form it closely resembles Harefield Red, but crops thinly, and has very distinct foliage which frequently burns under glass. Probably this variety will do much better out of doors.

Vick's Criterion.—Oval-shaped, but not so large or so good a cropper as *Criterion Improved*.

Vick's Criterion Improved.—This has a rounder and flatter fruit than its parent, not so rich in colour as many kinds, but is a good cropper early and late.

Sutton's Conqueror.—A ribbed flat red, a fine variety, good cropper, not equal to Harefield Red, and not so early or so handsome.

American Perfection.—Sent to Harefield by Mr. Bennett of Potters Bar, and 100 plants are now fruiting in pots, is a good grower, smooth, and showing fruit freely, and is evidently a large, handsome, promising variety, showing in clusters, but not yet coloured.

Jackson's Wonderful.—A tall-growing variety, very similar to if not identical with Hepper's Goliath, and not worth growing compared with Sutton's *Perfection* as a late variety.

Phillips' Perfection.—One of the handsomest in cultivation, and a long way ahead of all the Hathaway's *Excelsior* type, a capital cropper, and well worth growing.

Hackwood Park.—A bad setter early, but an extraordinary cropper late, large in size and of smooth form, some slightly corrugated, bright colour, and a heavy, solid fruit. One of the best varieties grown.

Harefield Golden Gem.—A seedling raised here and largely grown now, of medium height; fruit of good size, handsome and slightly ribbed, and it frequently reaches 6 to 8 ozs. in weight. It is an excellent cropper, early, and a constant bearer. Colour, bright golden yellow, and is really a first-class new variety.

Other varieties are also under cultivation at Harefield, but those enumerated stand out prominently as the best.—SOLANUM.

PREPARING FOR SPRING.

THE summer is now on the wane, and attention must be turned to those plants which produce such pleasing effects in early spring. Daisies are extensively employed, but how they have suffered! killed in some instances, and in others a few straggling half-withered stems are but the remnants of those effective spring bedders. Some, I feel sure, will have difficulty in procuring sufficient supplies, and those who may be thus placed will do well to bear in mind that a very useful spring-flowering plant may be found in *Limnanthes Douglasi*, of which a stock may quickly and cheaply be raised. It is one of the best of annuals for autumn sowing, and when of sufficient size should be planted in the beds or borders in which it is intended to flower at about 4 or 6 inches apart. It forms spreading tufts of leaves, from which in spring issue in great profusion its pleasing and effective white and yellow flowers. It is not too late even now to sow this, but which should be no longer delayed. It thrives in most soils made fairly rich. Then there are Primroses and Polyanthus, Forget-me-nots, Silene, Wallflowers in various colours, and many more which will need to be in fair sized plants now; and then when sending off bulb orders do not forget when ordering Hyacinths, Tulips, Crocuses, and Snowdrops, the bright gems of spring such as *Chionodoxa Lucilia*, *Iris reticulata*, *Scillas bifolia* and *siberica*, *Trillium grandiflorum præcox*, *Muscari lingulatum*, *Anemones blanda*, *appennina*, *coronaria*, and *fulgens*, *Narcissus Bulbocodium*, *Triteleia uniflora*, and the variety *lilacina*. These, and many more too numerous to mention, will all assist in making the display much more diversified and full of interest than even the most sanguine may anticipate.—E.

SHOW AND FANCY DAHLIAS AT THE NATIONAL DAHLIA SHOWS.

THERE is one most striking and interesting feature which these analyses bring out more and more clearly every year, and that is the prominent positions that are being assumed and retained by varieties of recent introduction, thus indicating that a decided and somewhat rapid improvement is taking place in the character of this grand autumn flower. This is more particularly noticeable in the Show classes. On carefully comparing the following lists with those published in the *Journal of Horticulture* last year, it will be seen that the newer varieties have, as a rule, during the past twelvemonth kept their positions better than those which have been out, say, six or more years. Although the abnormally dry summer through which we have passed has evidently affected some varieties much more adversely than others; yet as this would apply to both the newer and more established Dahlias alike, it can hardly have influenced the results to any appreciable extent. As regards the Show flowers there are six which have fallen three places since last year—viz., James Vick, Burgundy, James Service, Rev. J. Goodday, Ovid, and W. H. Williams; while John W. Lord and *Criterion* have both gone down four places: Alexander Cramond, John Wyatt, Modesty, and George Dickson five places: and Royal Queen (apparently one of those least able to resist a long drought) no less than seven places. Pioneer, George Smith, Rosy Morn, and Duke of Connaught do not appear at all in this year's list, although six additional names have been added to it. On the other hand, George Rawlings, Mrs. Harris, and Thomas Goodwin have each gone up three places; while Chris Ridley, Champion Rollo, Joseph Green, John Standish, Sunbeam, Miss Cannell, James Stephen, Harrison Weir, Lady Gladys Herbert, and notably that chastely tinted and exquisitely formed

variety Mrs. Gladstone, obtained no mention at all in the tables published last year. Indeed, if this year's exhibition were to be alone considered, Mrs. Gladstone would stand second only to the leading flower—i.e., the Hon. Mrs. Percy Wyndham.

The changes in the relative positions of the Fancies since 1884 will be seen on comparison of the two lists to have been, generally speaking, but slight; indeed, the only one among them all that has lost more than two places since last year is John Forbes, which has gone down three places, while Professor Fawcett and Miss Lily Large have both risen four places, and Chorister five. Peacock, James O'Brien, Polly Sandell, Maid of Athens, and Wizard make their appearance for the first time in any of these tables. It should, however, be mentioned that five more Fancy varieties have been tabulated this year in the Journal than in 1884. In 1883 no fewer than thirty-eight Fancy flowers were exhibited in the Show classes, but at this year's Show there were only thirteen. During the present autumn the following would seem to have been the least constant:—

James O'Brien.....	exhibited 4 times as a Show and 5 as a Fancy.
George Barnes.....	" 3 " " 5 "
Flora Wyatt.....	" 5 " " 10 "
Rev. J. B. M. Camm ..	" 4 " " 13 "

I find that at the three Exhibitions which have been held by the

National Dahlia Society there have been in all 3332 flowers staged for competition—viz.,

In 1883	692 Shows, and 239 Fancies.
" 1884	754 " 425 "
" 1885	837 " 355 "
2283	1049

Also that in these three years the Show kinds were on an average exhibited in about 160 different varieties, and the Fancy flowers in about seventy varieties.

When taking down the names of the Dahlias at these exhibitions I could not help noticing the very untidy and generally unsatisfactory way in which many collections were named. It occurred to me at the time how easily the appearance of these stands might be improved by the adoption throughout the Exhibition of a neat label of some neutral tint and of uniform size. These labels should, of course, for the convenience of the judges and visitors be secured to the stands immediately beneath the different flowers.

I am indebted to Mr. A. Turner of Slough and Mr. W. H. Williams of Salisbury for supplying me with nearly all the dates which were wanting in the tables published last year.—E. M., *Berkhamsted*.

TACSONIA MANICATA.

THE Passionworts comprise some of the most gorgeous of tropical climbers, but there are few, even of the tender species, which surpass or equal in beauty this magnificent plant. Although it is brought to us from

Fig. 46.—*Tacsonia manicata*.

equatorial regions, yet, from the altitude at which it is found growing (often 7000 feet above the level of the sea), it is a greenhouse climber.

In their habit of growth the Tacsonias resemble very closely the common Passion-flowers, being, like most of them, of vigorous growth, the shoots extending 10 or 20 feet in a season, according to the age of the plant. The resemblance between the two genera is indeed carried so far, that some of the most acute botanists of the present day are unable to give the precise grounds for the separation of the Tacsonias from the true Passion-flowers.

The chief interest of these plants centres in their elegant scarlet flowers. These are, at a glance, seen to consist of ten segments or divisions, the lower portions of which are united into a tube, surrounded at its base by three leaf-like bodies termed bracts. These bracts, which are shown in the engraving, are common not only to the Tacsonias, but also to nearly all the other Passion-flowers, though in a few species they are placed at a considerable distance below the flowers and are extremely small. In one or two species they are cut into hair-like segments, and give a very interesting appearance to the flower, as in the *Passiflora ciliata* and *P. foetida*. These bracts are not much larger in *T. manicata* than in many other Passionworts; but from the shortness of the tube

which is almost concealed when the flower is expanded, "it may not unaptly be compared to an arm thrust into a large loose glove;" from which circumstance it is presumed that Jussieu gave it its specific name of *manicate*, or gauntleted.

The fruit is not the least remarkable part of the plant. In *Tacsonia pinnatistipula* it is 5 or 6 inches in circumference, spherical, and when ripe of a yellow tint, hanging by the very long peduncle to which the remains of the flower are usually attached. The seeds are surrounded with a pulpy arillus of an edible nature, especially in a few species, which are not unfrequently cultivated for the sake of their fruit, as *P. edulis* and *P. quadrangularis*.

T. manicata may be increased by cuttings either of the old wood in spring or of short young shoots in summer, under a bellglass with a little bottom heat. When grown under glass most of the *Tacsonias* will ripen seed, from which they may be readily increased.

The specific name has been already explained; the name of the genus appears to be a latinised form of *Tacso*, that by which the plants are known in Peru. There are several species besides *T. manicata*, those best known being *mollissima*, *pinnatistipula*, *princeps*, *Van Volxemi*, and *grandis*.

We must not omit to observe that the shoots of the *Tacsonias* do not require shortening, but if they are too crowded they may be thinned out while young. When the growth is too rampant and sterile of blossom, a flowering habit may often be induced by training the shoots horizontally, or nearly so.—W. T.

GRAPES AND GRAPE JUDGING.

A RECENT article on the above, and the Grape Exhibition at South Kensington, have caused me to put a few thoughts on paper. I have again re-read my article in "our Journal" for October 13th, 1870, page 279, with some pleasure, for it seems to strike at the root of Grape exhibition. I have now several points to note, but first I would ask, Has not the judging at the last few Grape shows favoured the huge clusters of unripe, or, at least, not the ripest fruit, rather than the medium or smaller bunches of presentable size, colour, and ripeness. All honour is due to those who by their skill and perseverance can produce such clusters as I have seen of late, which must be very profitable from a market point, but are such bunches what we ought to see on the exhibition table?

The South Kensington Exhibition, good as it was, must have been disappointing. No doubt some of the Grapes from having been at the Palace did not look so fresh, and there was a weakness in several classes. As the aim now is to get the finest possible berries, this is sometimes done at the expense of colour. My contention, however, is that medium bunches with larger and better coloured berries are passed for the monster bunches with smaller berries and less colour. At the above Show judging should have been comparatively easy, the Grapes being staged in their own classes, as they should be whenever practicable. Judging mixed Grapes is a very different and difficult matter. No doubt the small number of entries in some of the classes was caused by the fact of growers, more especially private growers, not having their Grapes fit for table; market men have always the advantage in this respect. What we want is a good show in December, say the week before Christmas, just to see what is in perfection then. The South Kensington results were very gratifying to me so far as that goes, so I am not complaining of my own exhibits, but the opinion of several good men was the same as my own, though nothing pleases the general public better than the prizes going to the largest bunches. I should like to make a note of the two splendid bunches with large berries of *Gros Guillaume*, which when first cut must have been superb, now these were not clusters or double bunches.

When *Madresfield Court* is shown in a mixed class with *Alicante* and *Black Hamburgh*, at first sight the *Alicante* would have first place, but considering the quality of *Alicante* with either of the others, and *Alicante* would not have a place. I am fully aware of the qualities of *Alicante* as a late Grape. I had it in March of the present year next to *Lady Downe's* for flavour. As regards berries, *Madresfield Court* will generally surpass *Alicante*, but not in colour. Now, to my idea, *Madresfield Court*, if ripe, with good berries, even if slightly deficient in colour at the top, should stand before *Alicante*, and *Black Hamburgh* generally will stand last unless the bunches and berries are good. The *Madresfield Court* exhibited at the July Show, South Kensington, were grand. This variety is first-rate as a summer or autumn black Grape when well done, and now the culture of it is getting understood it will hold its own. Its two weak points are its liability to crack and want of finish in colour. The first defect, with patience, can be overcome by extra ventilation and less water at the roots. From the time mine show the least signs of colour, not only do I withhold water, but also cover the border with a good layer of straw to stop the damp rising, and the roots are entirely inside. Colour, or, rather, want of colour, is caused, I believe, not so much by overcropping as by want of fire heat. In other years, when I started them earlier, consequently using more fire heat, I had them much better in colour than I have now with starting late, but I gain this time by heavy crop of sound fruit. There is nothing like a good crop to keep them from

cracking, and if Vines are healthy it is astonishing the weight they will carry. Two Vines last year ripened 70 lbs. of fine fruit.

I expect *Gros Maroc* will be the general Grape in time, as it crops well and colours without any trouble.

Exhibiting is a trade of its own, and the large London shows represent the growers for market generally, but there is nothing like a good local exhibition. At these shows Grapes are only staged that are fit to place on the table, so that if not perhaps very large, there is quality.—STEPHEN CASTLE, *West Lynn, Norfolk*.

I CONSIDER that Mr. Iggulden has done gardeners generally a good service in bringing this subject to the front. It is one that badly wanted ventilating, for I cannot help thinking that many gardeners who are allowed to exhibit are doing wrong by cutting Grapes for exhibition in July and August, which "A Young Exhibitor" says "ought not to appear before the judges until September has well nigh passed into October." There are two sentences in Mr. Iggulden's article, on page 251, which I hope may be impressed upon the mind of every gardener who may chance to read them. They are as follows. After his able criticism on "S's" remarks on his former article on this subject, he says:—"It is quite certain that he would get no reward for them (meaning unripe Peaches, Nectarines, &c.) if he exhibited them; and exhibitors of unripe Grapes ought also to be made to feel that it is a very unwise proceeding to cut them." Again, he says, "Are they fit to send to table after the show is over? and, if not, ought they to be sacrificed?" These are questions which might well be asked when Grapes as green as grass are seen set up in the classes for white Grapes, and *Gros Colman* and *Alicante* staged in the classes for any other black in July. If there is one thing more likely than another to disgust employers and cause them to prohibit their gardeners from showing fruit we think this is it. I well remember seeing some so-called white Grapes staged at one of our large provincial shows, and could not help wondering what they would be used for after the show was over.

I hope now that the subject has been started that it will be thoroughly well threshed out, for it certainly is one of considerable importance. I am particularly glad to see *Madresfield Court* so justly praised by "A Young Exhibitor," and I consider that every possible encouragement should be given to growers who, even if they only produce this grand Grape in what may be termed second-rate condition, for, after all, are not Grapes for eating? Do not misunderstand me, for I am one of the strongest advocates for sending fruit to table perfectly clean and finished in every way, but the fine flavour of *Madresfield Court* should make up for any little deficiency of colour at the footstalks. However, I suppose that the Judges at the late Taunton Show will disagree with what has been written on this subject, and I fear also that very many of the framers of schedules are not aiming solely at the advance of horticulture in the highest sense, otherwise so many societies would not be completely wrecked by a wet day. I think it a pity that prizes are not offered solely for *Madresfield Court* at our summer shows. This would greatly encourage growers to persevere with it, and I feel sure that many who have almost lost heart on account of the berries splitting, would, by paying more attention to atmospheric conditions, eventually succeed. At any rate, such examples of judging as Mr. Iggulden quotes require some explanation, for even if we say nothing about the flavour of *Madresfield Court*, all will admit that there are hundreds of growers who annually produce good examples of *Alicante* who have not, so far, been successful with the former. Such adjudication is most certainly calculated only to aggravate the evil of which we complain.

I hope that the remarks from Mr. Iggulden and "A Young Exhibitor" will have the effect of mending matters in this respect.—WM. JENKINS, *Aldin Grange, Durham*.

THE excellent exhibitions of Grapes held recently in London and Edinburgh indicate the vast amount of interest taken in this superb fruit, and it must be a source of much gratification to many to find the Journal devoting so much space to the subject of Grape culture. There is hardly a week passes without some important hints being recorded, and the weekly questions which appear in your correspondence columns relating to the Vine show that the matter never flags; indeed Vine culture may be placed at the top of the list of interesting fruit subjects. Of late the notes on judging and exhibiting have commanded attention. Mr. Iggulden, in his complaints at page 204, wishes it to be understood that he does not grumble through being a disappointed exhibitor. He cannot be suspected of this, but let me ask him one question, Has his *Madresfield Court*, or any other of his summer Grapes, been passed once this season in favour of later varieties? "No one, I think," writes Mr. Iggulden, "will dispute the fact of the great superiority of *Madresfield Court* over *Alicante*." I will. Where there is one *Madresfield Court* grown for either private or market use twenty *Alicantes* may be placed against it. The *Alicante* is everybody's Grape. It will grow most luxuriantly either in the hands of professional or amateur. It never fails to produce bunches in the utmost profusion. They always set well, swell freely, colour superbly throughout, and keep sound and in splendid condition for months. Its value on the table may be reckoned from the quantity grown everywhere, and the great demand for it in the market. Such is the character of *Alicante*. *Madresfield Court*, on the other hand, frequently fails to form its berries properly, numbers of them split before they are ripe. When the points are black the back ends are often perfectly green. It is impossible to keep it for any length of time after it is ripe; and what with its splitting, inferior colouring, and non-keeping properties, it is distrusted by professional gardeners and shunned by amateurs.

In my opinion there is just as much credit in having the Alicante, or any other late Grape, in faultless condition in August or September as in having the early ones in good condition then. In fact the former takes more culture than the latter, and when the usefulness of the varieties is taken into consideration the late ones have it wholly. If Grape shows were held every month in the year "A Young Exhibitor's" ideas, page 251, might be worth something, but to speak of passing all Grapes not in season, irrespective of their condition, is a suggestion which no good judge would entertain. Madresfield Court is "A Young Exhibitor's" favourite black Grape. Most growers of experience prefer the Black Hamburgh to it. Scores of judges whose knowledge of Grapes is as deep and wide as that of Mr. Iggulden, are annually in the habit of awarding prizes to these late Grapes when they find them worthy of it, and this meets with the approval of the majority of cultivators.

Alicante is certainly a standard Grape. Madresfield Court is nothing of the sort, and never will be. At the Palace Show on September 4th only four examples of Madresfield Court were staged in its special class. The third-prize bunches were inferior, while amongst the eleven examples of Alicante shown the quality was so good that some extra prizes were awarded. I find that varieties which are in the habit of winning prizes are soon sought after and planted by the public generally. Those who follow this rule with Madresfield Court will be disappointed, but no one will ever regret planting the Alicante. I know one instance where it is grown in the garden of a marquis in this county. It is started early into growth, matures its fruit under the influence of the August sun, and from the beginning of September until March it eats like a crisp Black Hamburgh.

Grapes generally have been uncommonly good this season. I have seen hundreds of bunches in different parts of the country, and I cannot remember a year when colouring was so perfect. It is extraordinary the quantity of water Vines require at the root when in full growth, and this seems to be better understood now than many years ago.

Mr. Stephen Castle always writes instructively and interestingly on Grapes, witness his notes page 246. The cases of hurning he cites are peculiar; many Vine growers experience the same thing, but few can fully explain the cause. One Vine of ours, a Gros Colman on its own roots, went in much the same way in August. Another of this variety, grafted on Foster's Seedling, and growing next to the burnt one, is perfectly green in the foliage still.

I am particularly fond of the Foster's as a stock for Gros Colman. A friend of mine who owns two fine vineries, was induced by me, when planting them four years ago, to put in a rod of Golden Queen. It has always made wonderful shoots and leaves and larger bunches than I ever saw at Chilwell, but just when it begins to ripen the berries commence to show little black spots, which spread until the berries quite decay and fall. My experience or observation has never led me to ascribe such a character to Golden Queen, and I cannot understand it. Has anyone else observed any defect?

Golden Champion and Duke of Buccleuch do not make headway. I shall never forget the superb condition in which I have seen them at Dalkeith and Clovenfords, but the bunches generally seen at shows now-a-days are too ragged and small to be impressive.

The other day I read that huckets of gas tar placed in vineries would disgust the wasps and keep them out. Having charge of the gas-making here, I at once resorted to the tar-pump, filled some tins, placed them in the vineries, and after a week's trial the wasps are buzzing about inside as busy as ever. I know a gentleman who, in having his new vineries finished a few years ago, had the ventilators carefully covered with perforated zinc with holes just wasp-proof. They remain on always, and I believe they will soon pay for the little extra expense incurred in placing them there.—A KITCHEN GARDENER.

A MEETING of the Executive Committee of the PEAR CONFERENCE was held at Chiswick on Tuesday last. John Lee, Esq., in the chair. Present: Messrs. Veitch, Lane, Shirley Hibberd, A. Dean, Bunyard, Woodbridge, Roberts, and Dr. Hogg. It was decided that the Congress will be opened on the 21st of October and close on the 4th of November. Mr. Barron, the Secretary, reported that he had received notice of a very large number of entries, and that he anticipated the extent of the collections would be as great as were those at the Apple Conference, if not greater.

— A MEETING of the FRUIT COMMITTEE was held on Tuesday at the Chiswick Garden of the Royal Horticultural Society, John Lee, Esq., in the chair. Present: Messrs. Rivers, R. D. Blackmore, Bunyard, Lane, Woodbridge, Sutton, Silverlock, Roberts, Burnet, Willard, Veitch, and Dr. Hogg. A large number of new varieties of late Potatoes were dug and examined, and some of them were cooked; but, as in the opinion of the Committee it was too early in the season to judge of the merits

of late Potatoes, a further examination was proposed to be made after Christmas. The Committee then proceeded to an examination of the new Grape called "John Downie," which was growing in the early vinery, and they were unanimously of opinion that it is identical with Alnwick Seedling.

— At the City of London College a course of LECTURES ON AGRICULTURE, beginning on Oct. 6th and ending in May, will be given on Tuesday evenings by Mr. Bernard Dyer, F.C.S., F.I.C. The lectures will treat of soils, plant life, crops, manures, tillage operations, live stock, food, &c. Students are eligible to compete for the Lubbock scholarship of £10, the science studentship, and numerous college and other prizes. The Saddlers Guild also offer a prize of £5 5s. to the student who passes the best examination in chemistry and agriculture.

— "W. G." asks if any of our correspondents can advise him as to the best DRILL FOR BEET AND TURNIPS suitable for market gardening; also as to the best early Turnip suitable for northern climate and time for sowing? We shall be glad to publish the information requested.

— Mr. G. CUMMINS has sent us from Mr. Smee's garden, The Grange, Hackbridge, specimens of SUTTON'S WHITE CZAR RUNNER BEAN. We have never seen finer pods of any variety. Some of them are a foot long and 1½ inch wide, thick, fleshy, crisp, and excellent when cooked. The variety, we are informed, bears abundantly, and is regarded by Mr. Cummins as a valuable acquisition.

— Mr. WILLIAM HOLMES, Frampton Park Nurseries, Hackney, Hon. Sec. of the NATIONAL CHRYSANTHEMUM SOCIETY, has sent us samples of the new silver and bronze medals the Society is offering at their annual Show in November next, and which are also supplied to the affiliated societies. The die is a very artistic one, representing in relief the different sections of Chrysanthemums; incurved, Japanese, Pompon, Anemone, Anemone Japanese, and single varieties being arranged in a graceful wreath with foliage. The medals are extremely tasteful productions highly creditable to the Society, and will undoubtedly be greatly valued by the fortunate recipients.

— THE WEATHER has suddenly become very cold and winterly in the south of England, north and north-east winds prevailing. In the neighbourhood of London on Saturday morning a temperature 8° below freezing point was registered. In Dorsetshire and neighbouring counties there have been storms of snow and hail, also in Yorkshire, Lincolnshire, and the north generally. Dahlias and other tender plants show the effects of the frost, and the summer beauty of flower gardens is now destroyed.

— A CORRESPONDENT writes:—"In your report of "SOME THOUGHTS AND SUGGESTIONS ON FRUIT AND FRUIT-GROWING" on pp. 266 and 267 of the last number of the Journal, it is stated that the most popular variety exhibited at the National Apple Congress, held in October, 1883, was APPLE LORD SUFFIELD, but by referring to your issue of December 18th, 1884, p. 544, it will be seen that, in point of fact, B'enheim Pippin was the most popular Apple, it being classed in both culinary and dessert sections, obtaining an aggregate of 115 marks, or fourteen in excess of those recorded in favour of Lord Suffield."

— IN reference to a note on the MIDDLE TEMPLE CHRYSANTHEMUMS in our last issue, we are requested to state that though an exhibition of them will not be held this year the stock of plants will be retained. They have all been cut down for the production of cuttings. It is not generally known that the Temple authorities do not purchase Chrysanthemums for the Gardens, but the gardeners obtain all the newer varieties at their own cost, and have the privilege of disposing of cuttings to recoup themselves for the outlay. It is unfortunate that a show is not to be held this season, as the plants before being cut down were finer than have been seen in the Gardens for years, and an imposing display would have been produced. It does not follow that a Chrysanthemum show will not be held another year in the Middle Temple Gardens.

— "I HAVE just seen the beautiful new SACCOLABIUM HEATHI," says an Orchid grower; "and it is certainly a valuable addition to the always admired species of this genus. It bears some resemblance to Saccolabium Blumei majus, the spikes being 12 to 18 inches long, on which the white flowers are crowded, forming a dense cylindrical spike of much beauty, and particularly useful for comparison with the dark-flowered species. S. Heathi, I consider, will become a favourite in all the leading Orchid collections."

— Mr. W. ROBERTS, The Gardens, Slangwern Hall, Machynll

Monmouthshire, writes respecting the WEATHER IN WALES as follows—“Frost has made its appearance in this part of Wales rather earlier than usual. On the night of Saturday the 26th, the temperature registered 4° below freezing point. It has played sad havoc with outside flowers, such as single Dahlias, Sweet Peas, Tropæolums, and other flowers most valuable this time of the year. Iresines and Mesembryanthemums amongst the rest have suffered. It has been rather hard on vegetables such as Dwarf Beans, Scarlet Runners, &c.”

— A DINNER to celebrate the twenty-first anniversary of the EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY took place in Lyric Hall, Ealing, on Wednesday evening, 23rd inst. The officers and friends of the Society, and all classes of exhibitors at the Society's shows, to the number of 160, assembled. The Hon. Secretary, Mr. Richard Dean, presided, and was supported by the Right Hon. Spencer Walpole, the President of the Society. A very pleasing feature in the evening's entertainment was a presentation to Mr. Dean, which consisted of an illuminated address and a marble fourteen-day timepiece, presented by the gentlemen's gardeners and cottagers exhibiting at the Ealing, Acton, and Hanwell Horticultural Society.

— MR. C. ORCHARD, The Gardens, The Leigh, Coombe Warren, Kingston-on-Thames, writes:—“I have sent you a flower of *ARISTOLOCHIA GIGAS*, which is a curiosity, as are all the species of this genus. It is not often seen, as it is not very common. I saw the plant growing on the back wall of a greenhouse in the garden of a friend of mine at Claygate when on a visit to a few Chrysanthemum growers. It is a suitable plant for a lofty warm greenhouse or intermediate house on account of the fine foliage, and the curious shaped flowers is always an attraction to visitors.” The flower received is a fine one, and very distinctly veined with maroon on a pale yellow or creamy ground; it is one of the finest coloured forms we have seen, though much inferior to the remarkable *Aristolochia Goldieana* figured in this Journal, page 456, June 10th, 1880.

— MESSRS. COLLINS BROS. & GABRIEL, 39, Waterloo Road, S.E., send us a flower of *LILIUM SPECIOSUM RUBRUM CRUENTUM*, which they state is “a Japanese form. Several large beds of the variety at our nurseries, Hampton, are really grand, the plants being from 4 to 5½ feet in height against the Dutch variety only 2½ feet. Another fine variety is album *Kraetzeri*, pure white, altogether superior to the ordinary Album, which has a dark red streak on back of petals.” The variety is a most handsome one, of an intensely rich crimson colour extending nearly to the tips of the petals, which have a narrow margin of white, and a green line in the centre. The white margin brings the rich colour of the petals into splendid relief, and in company with the white variety named it must have a beautiful effect.

— “CAN any of your readers give me any information about *MIGNONETTE MACHET*?” writes a correspondent. “I have been told that a very fine variety is grown under this name on the continent, and that it has been introduced this year to England. It is described as of a strong floriferous habit, with tall compact spikes of extremely fragrant flowers, superior to any other variety yet grown. This is such high praise that I am very doubtful as to its accuracy, especially as we have so many fine strains now.”

— REFERRING to the APPLE CROP IN AMERICA, a Connecticut paper observes—“Apples have never been known to be more plentiful in this State, though here and there the crop has been blighted by insects. A ride in any direction will disclose tree after tree laden with Apples so that the limbs fairly bend beneath their weight, in some cases to the point of breaking. Even the miserable, scraggy, gnarly trees growing by the roadside have the fruit strung upon their branches as thickly as Onions suspended from a string in a country store. Under the circumstances it is likely that there are more Apples than can or will be consumed by the market, and as other States share this abundance with Connecticut, it is presumable that thousands of bushels will find their way into cider mills.”

— A MEETING of the West Wycombe Horticultural Society was recently held to make a PRESENTATION TO MR. G. T. MILES, gardener to Lord Carrington, Wycombe Abbey, in recognition of the services he has rendered to the Society as Judge during fourteen years. A handsome Chippendale cabinet of local manufacture was selected as a fitting object, and this was presented to Mr. Miles by Lady Dashford in complimentary terms, to which the recipient suitably replied. A complimentary dinner

was subsequently held, at which sixty gentlemen were present, the Rev. H. T. Young presiding.

— THE twenty-second Exhibition of the BRISTOL CHRYSANTHEMUM AND SPRING SHOW SOCIETY will be held in the Victoria Rooms, Queen's Road, Clifton, on Wednesday and Thursday, November 18th and 19th. Sixty-two classes are enumerated in the schedule for Chrysanthemums, miscellaneous plants, cut blooms, and fruit. A silver cup, value four guineas, is offered for six Chrysanthemums in pots; the National Chrysanthemum Society's silver medal, and the Royal Horticultural Society's Knightian bronze medal are also included, and numerous prizes are offered by local friends of the Society. The Secretary is Mr. Alfred Polkenhorn, 96, Egerton Road, Bishopston, Bristol.

— AROUND the central beds in the house devoted to succulent plants at Kew a BORDER OF *STREPTOCARPUS* was planted last year and has attracted much attention this season. The most noticeable has been the lilac purple flowered *S. Rexi biflorus*, but groups of the small but profuse white *S. pauciflorus* and the free lilac-flowered hybrid between that and *S. multiflorus* have also been greatly admired. Another remarkable species which is unnamed, and presumably has not yet flowered, is one that is said to grow at an elevation of 3 to 6,000 feet in the Transvaal. This produces a single leaf, which, when fully developed, is 6 to 9 inches broad and 12 to 15 inches long, very prominently veined. If the flowers are as distinct and striking as the leaves it will be an important addition to the genus. The border devoted to these plants is only about a foot wide and consists chiefly of peat, but it is astonishing what a number of flowers have been produced, and how much it has improved the appearance of the house.

— IN the same house *CEREUS NAPOLEONIS* is bearing a number of its handsome fruits, which are globular in form, 2 inches in diameter, and of an exceedingly rich crimson colour. Of several species of *Cereus* which produce ornamental fruits this is one of the best. *Cereus triangularis*, the Strawberry Pear, has had several of its enormous flowers, and *Pilocereus latefrons* has been bearing its white or yellowish flowers freely.

— THE SOUTHEAST-ON-SEA CHRYSANTHEMUM SOCIETY will hold their first Exhibition on November 10th, this year, in the Public Hall, Southend. Twenty-six classes are provided, for Chrysanthemums in pots, cut blooms, miscellaneous plants and fruits, the prizes being mostly of moderate amount. The Hon. Sec. is Mr. J. C. Johnstone, Creevelea House, Southend.

— THERE were recently several pretty and useful ORCHIDS IN FLOWER AT KEW, though this is not the best season for such plants, but the condition of the Orchids in this establishment seems to be steadily improving, and in the warm house the appearance of the side stages is much better now there is a carpeting of *Selaginella* and *Panicum*. The only objection to this is that it forms a harbour for insects, slugs, and other pests, but with care and watchfulness on the part of the cultivator such evils can be avoided, and anything is preferable to the bare stages and shelves too often seen in such houses. The handsome *Oncidium varicosum* had a grand panicle of its large yellow flowers, and neat it also in the cool house was a plant of *Oncidium incurvum* bearing three panicles, each 3 to 4 feet long, with numerous small white and purple flowers. *Stenoglottis fimbriata* is a curious Orchid, with purple-spotted leaves and rosy purple flowers, the lip in three narrow segments. *Zygopetalum Wendlandi* is a good distinct form with white flowers, the lip tinged with purple. *Satyrium Wightianum* is a member of an interesting genus of terrestrial Orchids far too seldom seen in gardens; this is a very pleasing species with bright rosy flowers in a close spike. *Eria stellata* has white flowers in a spike 8 or 9 inches long, but is chiefly remarkable for its delicious fragrance. A plant of *Saccolabium Blumei majus* had four handsome spikes of highly coloured flowers, and *Dendrobium formosum giganteum* had unusually large flowers 4½ inches in diameter, and eight in a spike.

— MR. W. BOTTING HEMSLEY states in *Nature* that the FORSTER HERBARIUM, a portion of the collections of Cook's second voyage, has been acquired by exchange from the Liverpool Corporation for the Kew Herbarium, and it will be incorporated in the general collection. Sir Joseph Banks and Dr. Solander accompanied Capt. Cook on his first voyage round the world; John Reinhold Forster and George Forster, father and son, were the botanists of the second voyage (1772-75), and Mr. Anderson, the surgeon of the expedition, collected a little on the

third voyage. From a statement in Sparmann's "Travels in South Africa," it seems that Forster the elder undertook the duties of naturalist to the expedition for the sum of £4000, and he took his son with him, then only seventeen years old, as an assistant. On arriving at the Cape of Good Hope they fell in with Sparmann, who at the instance and expense of Forster, was added to the scientific staff, and continued with them until the return to the Cape in 1775. Considerable collections of plants were made in New Zealand, many parts of Polynesia, and the extreme south of America, and smaller collections in some of the Atlantic Islands, including St. Helena, Cape Verd Islands, and Canaries. The collection now acquired for Kew is excellently preserved, and the plants mostly named and localised. It comprises altogether 1359 species, 785 of which were collected on the voyage with Cook, and the rest from various parts of the world. Roughly, there are 187 species from Polynesia, 119 from New Zealand, twenty-one from the extreme south of America, twenty-three from the Atlantic Islands, including all those described by Forster from St. Helena, and nine from Australia. Besides the foregoing, which are all phanerogams, there are thirty-six Ferns.

— AN American paper gives the following upon SUNFLOWERS AS FUEL. A correspondent having tried "turf," coal wood, and Sunflowers has settled upon the last named as the cheapest and best for treeless Dakota. He says: "I grow one acre of them every year, and have plenty of fuel for one stove the whole year round, and use some in another stove besides. I plant them in hills the same as corn (only three seeds to the hill), and cultivate same as corn. I cut them when the leader or top flower is ripe, and let them lay on the ground top for three days; in that time I cut off all the seed-heads, which are put into an open shed with a floor in it, the same as a corn-crib; the stalks are then hauled home and packed in a common shed with a good roof on. When cut in the right time the stalks when dry are as hard as oak, and make a good hot fire, while the seed-heads with seeds in make a better fire than the best hard coal. The seed being very rich in oil it will warm better and burn longer, bushel for bushel, than hard coal. The Sunflower is very hard on land. The piece of ground selected to plant on should be highly enriched with manures. In the great steppes (prairie region in the interior of Russia and in Tartary), where the winters are more severe than here in Dakota, the Sunflowers are, and have been for centuries past, the only kind of fuel used."

— A CORRESPONDENT of the *Tropical Agriculturist* thus refers to WATERCRESS IN CEYLON:—"In Moon's time—1824—the common Watercress (*Nasturtium officinale*, L.) was pretty well naturalised in Ceylon, and since then nearly every stream running through the estates in the Kandyan country has the Watercress growing in it, the plant being known to the Sinhalese as kakkutu pala. In reference to the idea of natural selection, we some time ago alluded to the facts recorded by Sir J. Hooker, that the Watercress introduced into New Zealand found such a congenial climate there that it grew to a length of 12 feet and 1 inch in diameter, and it cost Government £300 per annum to keep the mouth of one of the rivers clear of this introduction to enable the stream to be navigated. A correspondent who took a stroll on the banks of the Dambagastalawaoya from Cymru as far as Elgin a few days ago, informs us that seeing a dense mass of green vegetation on the other side of the river, covering the banks up to the level ground on the top, and not recognising it, he got a handful of it picked by one of the men in the lines close by, when he found it was a bed of Watercress, one of the top bits of which measured upwards of 3 feet in length and one-third of an inch in diameter, and he believes that entire plants in that bed measure 6 feet and half an inch, so that we can grow Watercress in Ceylon one-half the size attained in New Zealand!"

— THE sixth annual CRYPTOGAMIC AND BOTANICAL MEETING of the ESSEX FIELD CLUB will be held as previously announced on Friday and Saturday, October 2nd and 3rd, 1885, in the northern section of Epping Forest (Epping Lower Forest, High Beach, Monk Woods, Chingford, Buckhurst Hill, &c.). The head quarters for the meeting will be "The Roebuck Hotel," Buckhurst Hill, Epping Forest, and the following botanists, among many others, have promised their aid as Referees and Directors at the meeting. *For Fungi*:—Dr. M. C. Cooke, M.A., F.L.S.; Rev. Canon Du Port, M.A.; Mr. James English; Dr. Spurrell, F.R.M.S., &c.; Worthington G. Smith, Esq., F.L.S., M.A.I.; Dr. H. T. Wharton, M.A., F.Z.S., &c.; Arthur Lister, Esq., J.P., F.L.S. *For Mosses, Lichens, Algæ, and Phanerogams*:—Professor Boulger, F.L.S., F.G.S.; Rev. J. M. Crombie, M.A., F.L.S., F.G.S.; Dr. Braithwaite, F.L.S., F.R.M.S.;

Henry Groves, Esq.; Charles A. Wright, Esq., F.L.S., F.Z.S.; F. J. Hanbury, Esq., F.L.S.; E. M. Holmes, Esq., F.L.S.; David Houston, Esq., F.L.S.; F.R.M.S.; W. W. Reeves, Esq., F.R.M.S.; A. Vaughan Jennings, Esq. The management of the microscopical department will be in the hands of Frederick Oxley, Esq., F.R.M.S., assisted by Messrs. E. Letchford, F.R.M.S.; Charles Thomas, F.R.M.S., F.G.S., A. P. Wire; W. T. Christian, F.R.M.S., and many other members of the Club. An exhibition of specimens will be held in the large ball-room attached to the "Roebuck Inn," Buckhurst Hill. Exhibits of fresh and dried botanical specimens, microscopes, and microscopical objects, diagrams, drawings, &c., will be very welcome. The Exhibition will be confined to subjects from the vegetable kingdom, but not necessarily to the Cryptogamia, although that division will hold a very important place. The Friday's assembly is intended to be a students' and collectors' day in the woods, the evening being devoted to the naming and arranging of specimens. Saturday morning and early afternoon will be similarly occupied, and Saturday evening's meeting will be of the nature of a *conversazione*. Ample time will thus be afforded for careful examination of the specimens by the visitors present, and all possible facilities will be given to exhibitors. The members of the party on Saturday are requested to assemble at four o'clock at the "Roebuck," where the customary Club tea will be served at five o'clock; after which an ordinary meeting of the Club will be held solely for the proposal and election of members. The following papers will be read:—"The Uses of Fungi," by Dr. H. T. Wharton, M.A., F.Z.S.; "Some Botanical Mares-nests: chiefly Fungological," by Worthington G. Smith, Esq., F.L.S., M.A.I., &c. A series of large diagrams, illustrating the fungoid diseases of plants, being original drawings by Mr. Worthington Smith, have been most obligingly lent for exhibition by Messrs. Edward Webb & Sons, seed merchants, Stourbridge.

STEPHANOTIS AND GARDENIAS.

WE are all accustomed to hear these two plants praised so much that it would be something new to hear of something against them, but considered in some ways I think there might be more said in the latter way than the former. The pure colour and fragrance of both may be thought pleasing, but the fragrance of the Gardenia especially is so strong that not one person in a dozen can really enjoy it. The stems, particularly of the Stephanotis, are so short, that unless for wreath or cross-making they have to be wired before they can be used, and then there is nothing uncommonly attractive about them when mixed with other flowers. The flowers, however, may be good enough, and if they cannot be disparaged, what about the plants? It would be absolutely impossible to find two equal to them for harbouring insects, such as mealy bug, and I am of opinion that, considering the time it takes to keep them clean, in the majority of cases it would be profitable to be without them. We may clean the plants as thoroughly as possible to-day, and in a few weeks' time they are again smothered with mealy bug and other pests. Where men can be kept to do little else but sponge the plants may be fairly clean always, but in under-handed places and amateurs' houses they are a perpetual nuisance. I have heard the latter repeatedly say that they were never troubled to any extent with mealy bug until they bought in a Stephanotis or a few Gardenias, when the whole of their plants were soon infested. This should be well considered by all before introducing these two plants, and if no other place can be found for them than in a house with other plants or fruits, it would be much better to do without them. There are plenty of other flowers which are just as pretty and sweet, which require no more space, and certainly much less attention, that might take their place. I have thrown our Gardenias away, as they harboured so many insects; their fragrance was not appreciated, and by the time they reached London their pure white petals had become almost black. The *Encharis amazonica*, which now fills their place, is much more appreciated. The Stephanotis may share the fate of the Gardenias, and if I had my way I would not grow either of them in any house where other plants or fruits were being cultivated.—J. MUIR.

GARDENS NORTH AND SOUTH.

I WAS once travelling across the German Ocean with an American tourist who had left his "great country" to see the sights of little Europe, and what appeared to astonish him the most was the changes he was constantly experiencing, in what was to him a very short journey. "As to the weather," he remarked, "you never know what is coming in a day's run; and as if that is not enough to make one uncomfortable, you just go across a ditch like this, and your tongue is of no use except for 'liquoring.' I have had all sorts of weathers in a fortnight, and found three languages in 500 miles; but in my country, sir, we can calculate almost exactly about the weather, and can travel 3000 miles without having our baggage searched, and with one lingo—things seem badly managed in this old country." The Customs' regulations had irritated, and a slight attack of *mal de mer* upset my loquacious companion; but he was, nevertheless, right in the main. The changes are great over a

limited area in Europe, and especially is the character of the weather widely different in different and not far distant parts of our sea-girt isle; still we are so accustomed to them, and to act accordingly, as not to seriously complain of the "management."

The gardening press and London newspapers have given the world to understand how exceptionally hot and dry the season has been this year in England, and how difficult has been the task of farmers and gardeners in keeping their crops alive. "Scarcity of vegetation" has been the stereotyped cry. It has indeed been scarce enough in the south, but the "cry" must have had a peculiar sound to some northerners who have often had more rain than they wanted, and instead of being roasted by heat, they could tell of luxuriant, yet tender crops, being cut by frost in summer, and this within a radius of 200 miles.

A short time ago I had the opportunity of observing the great difference in the appearance of fields and gardens in the south with those in the north-midland part of the country. The change was very striking. In consequence of the extreme heat and protracted drought lawns and pastures were brown for miles in the south. Fruits could not swell in any satisfactory manner, vegetables could not be planted for weeks, flowers faded rapidly, trees were defoliated prematurely, and water vanished from streams and wells. It has truly been a trying and exhausting season to all engaged in the cultivation of the soil in the south of England; but a few hours' journey northwards and a change welcome and refreshing was experienced. Trees clothed with rich foliage, fields green, fruit fine as well as plentiful, vegetables abundant, flower beds full, water flowing freely in the streams, and—how different this from the south—Potatoes, Kidney Beans, Heliotropes, and Vegetable Marrows killed by frost in August.

I was not on a gardening tour, but rather kept out of gardens as much as possible, and left my note-book at home; but being in Bath at the time of the flower show the opportunity of visiting two "good men and true"—Mr. William Taylor and Mr. William Iggulden—was too great to be resisted, pouring rain preventing a call at Longleat by the way, and the kind invitation of Mr. Pratt could not be accepted.

Mr. Taylor's work in the gardens of Mr. Alderman Chaffin has been recently alluded to by "W. I.," and criticised by "J. S. W." Both those correspondents had justification for their remarks, for Mr. Taylor's new start in Vine culture is strikingly satisfactory, but cutting down Vines to within 14 inches of the ground is not the "extension" system, and an explanation was needed and given. The Vines so cut down were propagated and planted late and had not time to ripen, hence they were cut down to where the wood was firm. They have now made splendid canes and developed foliage of great persistency, with bold brown huds in the axils of the leaves. The Vines appear to have been stopped when they attained a length of some 10 feet, and the laterals pinched to one or two leaves as in the preparation of Vines grown in pots. That length of cane is ripened throughout, and only a foot or less will be cut off in pruning—just the portion where the main huds have elongated by the pressure of the sap. Many persons would cut more than half the growth away in the belief that a length of "4 feet is enough to leave for one year." Some others would "fetch them down" much lower, with the object of producing canes of startling dimensions next year, and in the hope of having "grand Grapes" the year after. Mr. Taylor is one of those gardeners who aim at producing sturdy canes well stored with nutrient matter, not to be cut away, but utilised; his method is not limitless, but what may be termed a modified form of the so-called extension system, and he is satisfied with the results, and well he may be, as the Longleat Vines were grown on that principle, and Mr. Pratt has had a triumphant season this year. His predecessor has also done excellently in his present charge, for he, too, has achieved a triumph in growing Muscats in pots, and on exactly the same method of pruning he is growing the permanent Vines planted out.

A word as to these splendid Muscats. I have had the advantage of seeing the best fruiting Vines in pots at the metropolitan and many provincial shows, but never saw any to equal Mr. Chaffin's examples. Mr. Bardney will be glad to hear that they have been grown in the manner that he has practised so successfully, and which a few years ago he first advocated so strongly in this Journal. They were raised from eyes in March, 1884, grown well during the season, and shifted into 18-inch pots last spring, when the growths were an inch or two long. With sound judgment in watering, that being of vital import, much finer Grapes are produced on Vines so repotted than if left to fruit in the pots in which they were grown, no matter how they may be top-dressed and supported with liquid manure. Repotted and well attended to, the bunches and berries are as fine as on Vines in borders, at least that was so in the case of the Black Hamburghs grown by Mr. Bardney at Norris Green, while finer Muscats than those cut from the Vines under notice have seldom been seen. I should scarcely venture to say so much in the absence of corroboratory evidence. This was afforded by Mr. Coleman of Eastnor Castle, who was one of the fruit judges at Bath, for he publicly stated at the luncheon that the best Muscats in the show were undoubtedly those in Mr. Chaffin's collection of Grapes, and if they had been placed in the Muscat class they would have defeated the fine examples from Longleat, which the second best pair from the pot Vines pressed closely. The best bunches were about 4 lbs. in weight, of perfect shape, full, and the berries superbly finished, "looking," as a critical examiner remarked, "as if a light was shining through them." They were not so large as the Longleat berries, but their superior quality was apparent, and good judges like Messrs. Coleman and Challis are not carried away by bulk, but give, as all judges ought, due weight to quality and "finish."

Nor were the Vines exhausted by the crop; on the contrary, it would

be difficult to find any Vines that have made stronger and better growth than these wonderful potted examples, and they will be fruited again next year. This year's wood of the extension cane I have no doubt is 3 inches in circumference at the present time, and the lower portion of the rod 4 inches. "Rooted through the pots perhaps," some may imagine. No, that is impossible, for the pots were stood over the hot-water pipes all the season. But how do I know that the exhibited Grapes that won such a high encomium as that referred to were produced by the Vines under notice? Doubts were expressed at the Bath Show as to their having been cut from pot Vines, and I may therefore as well set the matter at rest. As each bunch was cut by Mr. Taylor it was handed to me and passed over to Mr. Chaffin, who affixed them on the stands, and the manner in which they were staged showed that he was an expert at this work, as not a speck of bloom was removed in the process. I hope to see similarly fine bunches and well-finished fruit on the same Vines next year, but with larger berries, and then they will "take some beating."

As was stated in the report of the Bath Show, all the other Grapes exhibited from the same garden were cut from Vines from which all the roots had been chopped off to within 6 feet of the stems two years ago for the production of fresh fibres in fresh soil. The crop on these Vines is an excellent one, and the great number of bunches of Madresfield Court must be searched in vain for a cracked berry, yet all the roots are outside, but there is no damp air inside, and the grower is evidently of opinion that moisture in the atmosphere will cause tender-skinned Grapes to split.

Mr. Chaffin's patented system of glazing is eminently worthy of note. It is thoroughly distinct—durable, efficient, good in appearance, and, in the end, economical, as it obviates the necessity of painting. Strips of felt are attached to the bars on which the glass rests; others are attached to stout strips of galvanised iron an inch wide, which are screwed down on the glass, making it perfectly secure. The squares are 3 feet by 13 inches, and so arranged that the glass does not quite touch at the laps, so that there is a filtering of air through the roof, condensed moisture can find its way outside, averting "drip," and if a square is accidentally broken it can be removed by drawing two screws and another square put in in a minute. The plan is extremely simple, and its durability has been tested in the structures that have been erected for years; indeed, if the system had not been thoroughly good it would not have been adopted in the noble structure last erected, the owner of which is very practical and very earnest in promoting high-class Grape culture. He has been a leading public man in Bath for years, having been thrice mayor of the city, and the esteem in which he is held is embodied in valuable presentations, including a splendid oil painting of himself in his robes of office. His garden is his delight; his desire to see his skilful assistant prosper. The readers of the Journal will be glad to hear that there is good prospect of his doing so, and that he has so far nothing to regret in relinquishing his charge at Longleat.

Now for a few moments' reflection on a few pleasant hours spent with Mr. Iggulden at Marston. As has been previously stated, Lord Cork's residence is beautifully situated. The trees are grand, which means the soil is good, so good that the garden will grow anything without trenching, and better without it than with it on its substratum of clay, for the crops on a part that had been trenched were inferior to those on land that had been dug a spade deep. The manager of this garden has been taken to task for his denunciations of trenching, but so far from his practice being wrong, it would not be easy to find a better supply of excellent vegetables. There was, as he stated some time ago, "plenty of everything," and there is no fear that the abundance will not be maintained. A hot summer exactly suits such land, as the sun is continually drawing up moisture from the earth stores for the benefit of the crops; but on a dry subsoil there is nothing to draw, and the moisture from a foot of cultivated soil is necessarily sooner exhausted than from a bulk twice that depth, so that the peculiar character of the land must be taken into consideration in determining whether it can be beneficially trenched or not. There is danger in overtrenching some soils, whereas in others deep cultivation is essential for productive crops. Mr. Taylor found trenching worse than useless at Longleat, and it is precisely the same at Marston.

This garden has been wonderfully improved during the past four years. The Vines at the commencement of that period were what many persons would have regarded as beyond renovation, but by chopping off old roots and filling new soil with new, reducing the spurs on the old and training in new rods, Grapes are now produced fit for any nobleman's table, and some of the bunches, though not large, have secured many prizes in the best competition, the size, finish, and superior quality of the berries having, as they deserved, received the recognition of competent judges. The Muscats were "too far gone" to yield to the same treatment, and new Vines will have to be planted before first-class fruit is produced. Peach trees that I saw on a previous visit almost dead with the "yellows" have been restored, and now yield fine fruit abundantly. The evil was at the roots, and fresh roots in fresh soil have effected the cure. As the present is the best time for action in the renovation of exhausted Vines and enfeebled trees, an allusion to what has been accomplished is not unseasonable.

There is a fine wall of cordon Pears at Marston. These had a very worn-out appearance a few years ago, the leaves being yellow and fruit small. By removing some of the old soil from the base of the wall, adding fresh and mulching heavily with manure, the trees have been invigorated, the foliage is green and fruit good. It is dry exhausted surface soil that drives the roots of trees downwards into wet, cold, and unfertile subsoil, and the degeneration of the trees follows. The crop of Apples was good on bush trees, yet so large that ladders are needed for gathering the fruit.

Some time ago a statement of Apples bearing on "last year's wood" was questioned and a discussion ensued thereon. The best crop and finest

so well matured, and fruit buds do not form as a rule till the second year. That is perhaps the explanation of the difference of opinion that has been

FIG. 47.—APPLES ON LAST YEAR'S WOOD.

fruit are not unfrequently seen on wood of the previous year's growth in the south of England. In cold, high northerly districts the wood is not

expressed on that subject. Some varieties, it may be further remarked, bear more freely on the young wood than others do. The example figured

represents in a reduced form the crop of Hawthornden on wood produced last year at Marston, the branches being quite bent down with the weight of their load. Where the growths are fully exposed to the sun and air throughout the season fruit buds form freely enough on trees in favourable positions. Thinning early in summer is far more important than pruning in winter in the production of fruit buds; and if cultivators were to thin more and shorten the shoots less there would be more fruit on many trees.

Plants under glass are in excellent condition throughout. A very simple method of striking tuberous Begonia cuttings may be noted. A few inches of light sandy soil is spread on the north side of a wall, and the cuttings dibbed in it in the summer. Kept moist they root quickly, and form good tubers by the autumn. Some hundreds of plants were rooted in August and growing freely. A notable feature of the conservatory are Zonal Pelargoniums as wall-covering plants, Guillon Mangilli, Wonderful, and some others being ablaze with flowers from base to summit, and it is a question if any other plants could cover the space so effectively. On the outside of the mansion are some grand old Magnolias which produce their handsome flowers freely; and on the lawn is one of the finest Golden Wellingtonias in the country, the tasselled drooping sprays resembling at a distance plumes of yellow Celosias. Lord Cork takes great pride in his garden, and it is certain he would have a difficulty in finding a better all-round gardener than his present one, who in turn is well assisted by his foreman, Mr. Coombe, who will make a good gardener for someone by-and-by. A little gardening in the north will be referred to in a future issue.—J. W.

AMERICAN BLACKBERRIES.

THOUGH Mr. J. Muir should "more than once" have "decried" the Kittatiny and other American Blackberries, yet somehow they still live. No doubt after being so repeatedly denounced it must be very annoying to think that this "decried" fruit should find supporters who, strange though it may seem, still like them and still will have them, yet it is so. It is not to be expected that the Editor would like us to "air" our introductions in any other than in the advertising columns; but, as the introducers into this country of the Wilson Junior Blackberry, we would like to say that, if acceptable to Mr. Muir, we shall next year be very pleased to send to him a dish of this monstrous and, as we claim, greatly superior Blackberry. As Wilson Junior was not introduced until after 1884 (which was the year Mr. Muir says he planted his) he, of course, has not grown this magnificent variety, and we are assured that when he does even he will change his opinion.

Amongst many other items as to the first-class qualities possessed by American Blackberries, we beg leave to quote verbatim a passage from what we think all practical men will consider a most sensible lecture. We are alluding to "Some Thoughts and Suggestions on Fruit and Fruit-growing," delivered at Wrexham, September 11th, before the North Wales and Border Counties Pomological Society, by Mr. E. J. Baillie, F.L.S., and which, as it happens, appears also in that week's issue (September 24th) of the *Journal of Horticulture*, page 266.

In commenting upon the American Blackberries this gentleman concludes as follows:—"The Blackberry presents another feature which should commend it. As a decorative plant for old walls or old fences it has few equals, and whilst pleasing the eye for the greater part of the year, as it is always interesting and attractive, from its first early leafage in spring to its rich autumn foliage, which is not impaired by ordinary conditions more or less affecting other ornamental plants, and the leaves do not fall, as a rule, until quite late in the season. The varieties of this fruit best adapted for cultivation are the Wilson Junior, Dorchester, Lawton, and Parsley-leaved."—VICCARS COLLYER & Co., Leicester.

CHRYSANTHEMUM NOTES.

THE BEST METHOD OF STAGING CHRYSANTHEMUMS.—Two interesting classes are provided in the National Chrysanthemum Society's schedule of the Show to be held on November 11th and 12th at the Royal Aquarium, Westminster—namely, for "the best method of staging Chrysanthemum blooms for exhibition without cups, and with or without boards." One is for twelve incurved and the other for the same number of Japanese, a prize of two guineas being offered in each, and it is especially provided that the prizes may be withheld "unless a method of general practical value be submitted." We have had some inquiries respecting these classes and therefore give the full particulars, as there are probably others who are interested in the matter. Unquestionably it would be a great advantage if a less formal method of showing the blooms could be adopted than is at present practised, or if it could only be applied to a few classes it would serve to diversify the effect.

CHRYSANTHEMUMS AT CAMBERWELL.—Active preparation is being made at Mr. Davis's nursery, Camberwell, for his annual exhibition of Chrysanthemums, there being about 2000 specimen plants of the best varieties. Some of these are already being placed under glass in the handsome show house which is now devoted to them, and they all look as promising as could be wished. The foliage is vigorous and the growth strong, but not too

luxuriant, and the buds look clean and free. The early-flowering varieties are still beautiful, and it is impossible to over estimate their value at this season when flowers are becoming scarce. It is unnecessary to repeat the names of the varieties as they have recently been described in the *Journal*, but a word of praise is due to Madame C. Desgranges and its beautiful yellow companion, G. Wernig. Both are floriferous varieties and come grandly under glass, the blooms being larger and purer in colour than when out of doors. Indeed, I am told one grower has been selling blooms of Madame Desgranges for some weeks past at 3s. per dozen, and that he has cut as many as twenty dozen at one time from a small house.

Numbers of new varieties are under trial and no doubt some will be found meritorious, but a rigorous system of selection is being adopted, and all that are not distinct will be destroyed. The early-flowering bronze-coloured Mons. Pynaert Van Geert is proving a variety of sterling value, being extremely free, of a pleasing hue and pretty form. Bouquet National is a good companion for it, of a rosy crimson tint and equally free.

MANURE FOR CHRYSANTHEMUMS.—Various practices are recommended by different growers in the supply of manure, either liquid or otherwise, to Chrysanthemums, and with care no doubt they can all be made to produce similar results. One of the simplest and most efficacious stimulants is that employed by Mr. Davis with great advantage. This is sulphate of ammonia, which is used for weak-growing plants or when the applications are commenced at the rate of half an ounce to the gallon of water, increasing the strength of the liquid to 1 oz. to the gallon. It readily dissolves and is quick in its effects upon the plants. Clay's Fertiliser is also useful for these plants, and is strongly recommended by many.—A.

LATE CHRYSANTHEMUMS.—I see by the schedule of the National Society that an exhibition is to be held in the middle of January for late Chrysanthemums, and no doubt it will prove very interesting. It will enable the public to see that the Chrysanthemum season can be extended over at least six months of the year, and it will also show what varieties are the best suited for late flowering. Might I suggest that a few prizes for late Grapes offered at this Show would add greatly to its usefulness and exactly meet the wishes of many gardeners?—A SURREY GARDENER.

TOMATOES FROM CUTTINGS.

I CAN hardly agree with "Kitchen Gardener" on taking cuttings from Tomatoes for early use in spring and in the autumn. As he does not state which cuttings we ought to take, some might be misled. I have cut ripe Tomatoes in March, and I hope my few hints will be useful to others.

In the first place I sow seed of the Old Red the first week in September, place the pots in a warm house until the seedlings appear, then remove them into a cool house, where they will get plenty of light and air. As soon as they are ready I pot them into small 60's, keeping them shaded till they get hold of the fresh soil. At the end of the month they will be ready for large 60's. In this size I keep them until the first week of the new year, when the plants will be about 9 inches high. And now for the cuttings. Where am I to get them from unless I cut the plants down? This I do, taking care to leave about three eyes on the plant, and these come in for succession. I take the head off the plants for my cuttings, because my experience as a Tomato grower has shown me that the best fruits were had from the leading growth. But this practice I only recommend where Tomatoes are grown in pots and where they are wanted early in the year.

The Tomatoes sent to you with this note are grown in boxes on the north side of my early vinery, which is a span-roof house, and are cut from my second plants this season, my early plants being over in June. These are grown in boxes in the open, and are brought into the vinery as soon as the old plants are cleared out.

My reason for writing this note on Tomatoes from cuttings is to point out which cutting ought to be taken to get early fruit. No Tomato pays me so well as the Old Red, for fancy sorts will not fetch any more in price, and where I get a pound of one of them I can cut six of the Old Red.—J. W. L.

[We have seldom if ever seen finer fruits than those sent by our correspondent.]

SEASONABLE HINTS ON FLORISTS' FLOWERS.

AFTER a very trying season it will now be necessary for all growers of florists' flowers to make ready for the coming winter, and to be prepared for all eventualities, as it is impossible to forecast, although the probability is that after two such mild winters it will be better to be prepared for a severe one.

AURICULAS.—Although I shall not myself move any collection into winter quarters just yet, many will in cooler latitudes be ready to move theirs. I do not think that I have had a larger per-centage of autumn-

blooming plants than usual, notwithstanding the hot and dry weather that we have experienced, although we are more subject to this than those who grow them in the cooler climate of the north of England, and I can quite understand how it is that Mr. Horner has a smaller per-centage of them than Mr. Douglas. I believe neither method of cultivation or time of repotting makes any difference, but just simply the climate in which they are grown. It will, however, now be necessary to carefully examine the pots, and see that after these heavy rains we have had the frames have been watertight and no plants are waterlogged, or the drainage have been disturbed, for of all the enemies to the successful culture of the *Auricula* none is so fatal as excessive wet, especially if the drainage has been disturbed. As after the summer the surface soil of the pots will probably have become caked, it will be well to stir it up with a blunt stick, and examine carefully the collar of the plant for woolly aphids, for although we have perhaps overrated the injury that this pest does to our plants it will be as well to get rid of it there. I found that although at repotting time there was hardly a trace of it on many plants, I have now got it on several of them; and although its injurious effects to the roots have been denied, yet all seem to think its room better than its company about the neck of the plant. Those who may have a desire to commence their cultivation, or add to their collections, have now a better opportunity of doing so, as I see that the collection of the late veteran grower, Mr. Alex. Meiklejohn, is in process of sale, and in it the crack sorts such as George Lighthody, Raifham Hero, &c., are to be had for 5s., and older sorts at greatly reduced prices.

CARNATIONS AND PICOTÉES.—Notwithstanding the dry season I find that layers of these have rooted well. The time has now arrived to prepare for wintering them. They may either be potted singly in small pots or in pans, which is the most usual way—in 48's. The compost for this purpose should be the simplest possible—good loam, with an admixture of road grit or coarse gravel. To keep it open is the best, as the object is not so much to stimulate growth, but to keep them in a sound healthy condition during the winter months. Those who, like myself, grow them in beds will now be preparing to plant them out. It is easier to do so in the autumn than in the spring, and I have found that there are very few losses during the winter. I always keep a few in pots for the purpose of making up deficiencies. The beds should be 4 feet wide, and the plants placed at about a foot apart. When they are planted it is well to put a small stick to each, tying the plant loosely to it, so as to prevent its being loosened by the wind. For the same reasons they should be planted firmly in the soil. As I have before said, these instructions are not intended so much for exhibitors as for those who desire the enjoyment of the flowers in their own gardens. For exhibition purposes to grow them in pots is almost a necessity. A good garden soil which has been well cultivated previously is admirably suited for them.

DAHLIAS.—The first frost will destroy the beauty of the various sections into which the Dahlia is now divided; but although the foliage is destroyed it will not be necessary to immediately lift the roots. However, the operation cannot be much longer delayed. A dry day should be chosen for it, so as not to have too much earth adhering to the tubers. They should then be placed in an airy situation free from frost to dry for a time before storing.

GLADIOLI.—These, too, are now losing their beauty, although they are not so susceptible of frost as the Dahlia, and need not be lifted yet; indeed, it is better to defer that to the latter end of the month (October), but the beds should be carefully gone over, and when seed is not wanted the flowering stems should be cut off, for there is little doubt that the seeding process weakens the corms. Where any corms have gone wrong it is better to take them up at once.

PANSIES.—This has been a trying season, in the south of England at any rate, for these plants, the long drought having completely destroyed the plants, which no amount of watering seemed able to save. This no doubt is one of the reasons why the Pansy is not so popular as it used to be about London. I had last year a very pretty collection, but have been unable to save more than three or four kinds. Where they are grown in pots the plants will now be ready for potting off into thumbs, and after remaining close for a few days until they are rooted may then be transferred to a frame facing south at present. Should, however, the weather be warm and sunny it may be as well to leave them in a north aspect for a little while longer.

PINKS.—Rooted pipings from the propagating frames or beds may now be planted out into beds prepared for them. This is another of the old florists' flowers which has fallen on hard times as far as the south of England is concerned. Mr. Turner, indeed, occasionally lets us see a stand, but otherwise it is almost unknown in the south; in Scotland it is still cultivated with more or less of success. The beds should be prepared as for Picotées, but the plants do not require to be so far apart.—D., Deal.

SOME THOUGHTS AND SUGGESTIONS ON FRUIT AND FRUIT-GROWING.

[A Lecture delivered at Wrexham, Friday, September 11th, 1885, before the North Wales and Border Counties Pomological Society, by Mr. E. J. Baillie, F.L.S.]

(Continued from page 267.)

THE different methods of cultivation have an important bearing, and it is both astonishing and amusing to find how doctors differ upon the points at issue. I read a most interesting account in one of the daily papers a few days ago of the surface system adopted with such success by Mr. Walter Kruse. He has carried on a very inter-

esting and instructive experiment in fruit farming during the past four years in the county of Kent, and the results have been so satisfactory that the system adopted may be considered, in the opinion of competent judges, to be worth the study of those interested in fruit-growing. Its peculiarity consists in this, that cultivation in all its forms is applied only to the surface of the ground. No digging is allowed. The garden hoe and the pruning knife are practically the only implements used on the farm. Not much work is found for the latter, as Mr. Walter Kruse, the originator of the system, and who at present stands alone in carrying it out, is of opinion that to get a large crop of fruit there must be plenty of wood for it to hang upon. The hoe, however, is freely employed to "tickle the ground," and the result seems to be that it "laughs into a harvest." The objection to digging is founded mainly on the injury which is commonly done to the roots of trees, especially at their extremities, where they are often torn and broken by the spade. As manure is only used as top-dressing, there is, of course, no necessity for digging in order to admit the fertilisers into the subsoil. The dressing is very rapidly absorbed, and consists to a great extent of phosphates in the form of bones crushed to quarter-inch size. The yearly expenditure for manure comes to from £10 to £13 per acre. By this superficial culture the roots are encouraged to keep near the surface, and take advantage of the upper and more nutritive soil; while, by the undisturbed formation of fine fibrous growths, innumerable feeders to the sustenance and health of the trees are produced. It has long been an axiom of fruit-growing in Kent that the roots of Cherry trees must not be interfered with, and in many old orchards a broad circle of green turf may be seen surrounding them, designed for the protection of the roots; but the curious and unintelligent part of the procedure is that the patch of grass only extends where the roots are thick and strong, and hardly liable to injury; while further out, where they are tender, the spade or the plough is used unmercifully. Mr. Kruse makes a great point of carefully protecting all this delicate growth. An advantage claimed for this system of surface culture is that, the soil being never broken up for more than an inch or so, evaporation is comparatively slight, and in dry seasons the reserve of moisture in the soil does not become easily exhausted.

Upon this question of cultivation there is an interesting pamphlet published by Pitman, of Paternoster Row, and issued by the Vegetarian Society, Manchester, the work of Mr. E. A. Kynaston, who writes under the title of "Head Gardener." This pamphlet is unique, and in every sense of the word original. Many practical growers will not accept his views; but whatever may be thought of the theories there advanced, his methods have, according to Mr. Kynaston's statements, invariably resulted in securing fruit in abundance and of excellent quality. The secret of the system is careful feeding. Mr. Kynaston maintains that trees subjected to the treatment he recommends are endowed with a constitution which enables them to resist the often disastrous late frosts which tell so seriously against trees not so strengthened. We have no time to pursue this question here. One remarkable fact I should like to mention with regard to Mr. Kynaston's method is this, the trees are not checked by removal as is ordinarily the case, but almost invariably come into immediate bearing. I quote from a letter which I received in June, 1884, as follows:—"June 19th, 1884. Dear Mr. Baillie,—I forward you by parcels post a sample of fruit gathered from trees that were growing in Messrs. F. and A. Dickson & Sons' nurseries at Chester as late as the middle of January last. Five Cherry trees were sent, and all are bearing well; and other fruit trees that were forwarded towards the end of January have mostly set their fruits, many of them with the abundance of old-established trees. . . . Many on reading this might say, 'Ah! but you must have had fine weather.' This, however, was not so, for the spring with us has been characterised by late frosts, cold nights generally, bitter east winds, and excessive drought. Now all this shows (1) what really good trees can be made to do when carefully planted and thoroughly cultivated; (2) that it is a great mistake to suppose that weather alone is responsible for the destruction of our fruit crops." Mr. Kynaston is an enthusiast in the matter of fruit cultivation, and his own little garden always gives evidence to the successful home application of his methods. It is at any rate evident that for the proper production of fruit we must have a careful cultivation, and I believe that were our fruit trees fed and tended carefully we should hear less of the climatic difficulties which terrify many and prevent a more rapid extension of the orchard of hardy fruits.

There were one or two other aspects upon which I wished to touch—*i.e.*, storage of fruits, the decorative character of some kinds, shelter, and the planting of wastes such as hedgerows and railway embankments; but I feel I must have reached the limits of your patience, and will only ask you to bear with me whilst I briefly refer to one of the most important elements in the matter we have discussed this evening. I allude to the education of the people in relation to the dietetic value of fruits. At present they are regarded as luxuries, or as an addition to a meal that is essentially complete

without them. This ought not to be so. Fruit must be recognised as a staple article of diet before fruit-growing will claim its proper place in the national economy. I do not plead the claims of the Vegetarian Society, but I would strongly urge those who have opportunities for moulding the thought and practice of others to give some amount of study to the principles advocated and facts adduced by that Society. They constantly invite and urge the attention of all earnest patriots and politicians and of all holders and occupiers of land to the importance of the cultivation of fruit as an auxiliary food supply, and urge the planting of fruit trees in all gardens, hedgerows, and on waste lands as a suitable, profitable, productive, and healthful industry; and in these times of scarcity of food, diseases among cattle, and great national distress, especially commend to landed proprietors and public corporations, on the grounds of both utility and beauty, the systematic planting of fruit trees along railways, roadways, river ways, canal ways, and wherever practicable. It is to be hoped that fruit will be made so popular as to be found not only upon the silver salvers of the wealthy, but upon the everyday table of the middle classes and upon the plates of the poor.

But in conclusion, to return to the more immediate work in which you are engaged. I have asked myself the question what a local pomological society ought to do. Well—

1, It ought to make a kind of survey of its district, indicating upon a map and noting on its record the places where fruit is grown and the areas of such places.

2, It ought to have a reliable record of the kinds of fruits grown upon these farms and gardens, under what conditions, and with what results.

3, It ought to see that the horticultural papers and the standard gardening works are readily accessible to the public as far as this may be possible, say through the medium of the free library or otherwise.

4, It ought to keep a kind of meteorological journal, giving reliable data of the weather and climatic changes, so that observations could be made and facts of so much importance reliably registered.

5, It ought to encourage fruit culture through the medium of local exhibitions, offering prizes, not in money, but in fruit trees of good kinds, for the best exhibits.

6, It ought to undertake the naming and classification of fruits submitted to its officers by growers.

7, It ought to educate the cottage population and families of the poor in the matter of food and household thrift by means of leaflets, pamphlets, and lectures, pointing out how fruit may enter much more generally into daily use as an article of absolute dietetic value.

8, It ought to experiment as to different modes of treatment and methods of cultivation, carefully noting and recording results.

9, It ought to endeavour to establish centres of sale. This should be one of the most important and helpful of its duties, as under existing circumstances fruit is carelessly gathered and picked up in the country districts at a price which cannot be remunerative, whilst it is sold in the large towns at prices placing it beyond the reach and free use of the poor.

10, All these facts ought to be carefully embodied in periodical reports and journals, to be circulated amongst the members of the society, and the book would thereby become a valuable work of reference and guidance for all interested in pomology.

I hope your Society will recognise the importance of its work, the extent of its mission. The extension of these principles is the extension of what Bacon has designated "the purest of human pleasures;" whilst the diffusion of these principles among the poorer classes will be adding materially to the most important of the benefits of a rightly directed occupation. There are few who will not readily engage in the work when convinced of the comfort, health, and gains derivable from it. There is in the principles we have been advocating everything that tends to endear a man to his home and make him patriotic in the best sense of that much-misunderstood term. Therefore the success of every such Society as yours means direct gain not only to the social but to the national economy.

[The lecture was illustrated by specimens of fruits of most desirable kinds for the district, and by a series of beautifully executed drawings of Pears and Apples. The Chairman, Thomas Chilton, Esq., of The Elms, Gresford, complimented the lecturer, and gave some most interesting particulars bearing upon the subject before them; and remarks were afterwards made by several gentlemen, including Mr. T. Bennion, Acton, Mr. Humphries, Mr. G. Cromar, Mr. Jones, Secretary of the Society, and others. The usual votes of thanks brought a most interesting meeting to a close.]

NOTES ON PLANTING SHRUBS.

ALTHOUGH, in the general routine of gardening operations, each season has its peculiar duties, which, if not done then, often tell for the

remainder of the year, or rather until the return of the same period again, yet there are periods in which certain operations seem to call for more special attention than others, as those relating to the spring and early summer. The progress then making renders it imperative for good cultivation that every seed or plant then requisite to commit to the earth should be done without delay, in order to meet the requirements of after-times; and a little more than the usual energy displayed at that time will, in most instances, be rewarded with corresponding success, and more after leisure. Now, though it would be wrong to say that the present season, September, has not important duties of its own to be performed, and these increased, too, by the wet weather we have had, and may still have, yet, when circumstances render any extensive outdoor alteration necessary, this is not a bad season to get on with it; for the most of our shrubs, especially the evergreen ones, move and plant with the best chance of success just now; and when we consider the many advantages which early operations have over late ones, it behoves all those contemplating such change to be on the alert, in order to avail themselves of all the advantages fine weather commands, which is certainly more likely to occur in this month than the two succeeding ones.

Wherever, therefore, new shrubberies are to be made, old ones altered or remodelled, or solitary specimens taken up and replanted, the present is certainly better than a later season.

Turf may also be included in the same category. Flower beds, however, that are perhaps under a heavy crop of plants, still ornamental, must be left alone for some time, unless under special care, when they might be sacrificed to the sweeping effects of a change; however, the arrangement of them, and the remodelling of a flower garden, whether on the geometric or desultory plan, I willingly leave to others; suffice it to say that the more formidable work of making new walks, roads, shrubberies, or of levelling and laying down turf, cannot be done at a more suitable time than the autumn; besides which, the commencement of such things sufficiently early in the season gives greater hopes of their being finished in time, should adverse weather or other circumstances intervene; but it certainly is advisable to get all the planting of shrubs and trees done as early as possible, in order to gain all the benefits which the autumn affords to their attaining fresh roots; and being in other respects established in their proper quarter before winter sets in. In addition to this, turf that is laid down now will unite and grow before winter prevents it, and present that uniform appearance so much desired. Deciduous trees had, however, better remain until their foliage be a little more ripe; it is not necessary that it should all have fallen off, but sufficiently matured to drop off without force; but the whole class of hardy evergreen shrubs might be planted now with a better prospect of their doing well than if the operation was done at any other time, other things being the same.

Prior to the commencement of any large alteration it would be advisable to consider well the various points on which such alterations bear, as it would be gross mismanagement to bury all the good soil in a large hole or hollow place merely for the purpose of rendering a certain spot of ground level, or otherwise agreeable to the eye; such an alteration might suit the purposes of a road surveyor or builder, but not the cultivator of plants. This point may therefore be borne in mind at the beginning, so that by arranging the trenching, all the good soil be retained at the top, and if it be in turf or pasture some of the bulk might be preserved for any purpose it may be wanted for, whether that be to relay again or decay for use on the potting bench. Of course its removal is so much loss to the ground it came from, and it need not be done in those places where it is wanted for the benefit of the plants, &c., intended to be taken there. However, these matters must be determined by the nature of each respective case; only one thing we would strongly urge, that when it is removed for any purpose its place ought to be supplied by something else that is good added to the ground, for if the well-being of the shrubs, &c., be an important point (and it often is so) a liberal allowance of substantial food must be allowed them to grow in; this may often be secured to them without the importation of much fresh material when the most is made of what is there. This we therefore strongly urge on our young friends to see to without delay, and before they commence operations, for it will often happen that ill-directed labour buries and destroys much valuable matter before it be aware of the uses it might be applied to. However, on ground approaching the extremes of stiffness, or dry, hungry lands, the addition of matter of a contrary description will be attended with a beneficial result, while in these extreme cases the selection of plants suitable to each ought also to be carefully studied, in order that the best may be made to meet the individual cases.

Thus, certain plants delight in a dry, gravelly, or chalky soil, others preferring a stiff loam, while the beautiful class called American plants like moist peat, but do not object to grow in a cool soil of another description, but have a decided objection to chalk, or soil in which lime predominates. This latter substance, being directly opposed to that in which they thrive, ought never to form an item in the same mixture as peat, for, though a peat bog may be ploughed up and the admixture of lime may do much for destroying that fibrous matter with which it is bound together, yet we are far from certain whether this is not affected by the annihilation of some of its properties most necessary to retain for the purposes of plant culture; if, therefore, your gardening operations extend over any tract of ground of this description, you may rest assured that you have found out the best possible site for the most beautiful class of flowering shrubs we possess, and before anything else is done, consider well how much of it you can allot to this section, for some expensive alterations will be necessary to make it available for other plants, which, after all, would not look so well.

Turning from the peat-bog or morass to one of a decidedly opposite nature, "the sand-bank," the number of plants available here is limited; yet we have seen a large embankment formed by a railway cutting rendered very interesting by such plants as Box, Furze, Yew, common Laurel, certain Privets, &c. Not that they all presented a thriving appearance, for, excepting the wild Juniper, few did not give signs of wishing for more nutritious food; yet they grew and looked tolerably well, and which would in any other case have been a barren mound became an interesting clump, for even grass would not have grown on it in anything like a satisfactory manner, for the least drought would have turned it brown and unsightly.

Even hills of entire chalk are scarcely sterile, as the common Yew and Juniper are found wild there where the coating of earth is very slight indeed, while such a position would be death to the Rhododendrons. Now, as each class presents ample variety, it behoves the careful cultivator intending alterations or adding new features to his grounds to consider well the various plants adapted to each particular case, and to act accordingly; for be assured that no after-management, however skilful, can so far alter the condition of a plant as to reverse its constitutional habits and wants.—R. N.

EXHIBITING CHRYSANTHEMUMS.

HAVING been desired to explain the manner in which Chrysanthemums are arranged in stands and conveyed to exhibitions, we requested Mr. Molyneux to favour us with a sketch of his stand and travelling box. He has obligingly complied, and the engravings and specifications will, we

Fig. 48.—Chrysanthemum Box and Stand.

trust, enable intending exhibitors to provide themselves with the articles represented. The stands for twelve blooms are 2 feet long, 18 inches wide, 6 inches high at the back, and 3 inches in the front. This is mentioned here, as the figures on the stand are somewhat indistinct. It will be seen that there is sufficient height for the blooms when the stands containing them are placed in the box, the space being one-eighth of an inch wider and longer for their reception.

SPECIFICATIONS FOR CHRYSANTHEMUM BOX AND STAND.

The box to be made in cupboard-form of three-quarter-inch well-seasoned American pine, dove-tailed together at the angles, the sides, top, and bottom to be rebated for the back. Plant a rounded nosing as shown to the top of the box and a small chamfered plinth round the bottom.

The door to be clamped top and bottom, as shown on sketch, and to be hung to fall in flush with the sides of the box, the door to be hung with one pair of $2\frac{1}{2}$ -inch butt hinges, and to be fitted with a cupboard lock with, say, two keys. Fix a strong chest handle on each side of the box. It will be noticed that when the stands are placed in the box the door closes tightly against them, thus preventing any movement during transit.

The clear inside size of the box should be 2 feet $8\frac{1}{2}$ inches high, 2 feet $\frac{1}{2}$ inch wide, and 1 foot $6\frac{1}{2}$ inch deep from back to front. The box is intended to hold four stands, each stand arranged to hold one dozen

blooms. The stands are made with tops half an inch thick, and the two sloping sides three-quarters of an inch thick, the holes to be spaced as shown on sketch. The runners for stands to be seven-eighths of an inch and half an inch, and screwed to the sides of the box as shown.

It may be noted that the sizes of the stands as figured on the sketch are the regulation size insisted upon at the principal shows.

OLD AND NEW FLOWER SEEDS.

"Sow seeds as soon as ripe" is the advice generally tendered, and that it is essential with some seeds there is no doubt, while with others the case is not quite so clear. New Primula seed, whether it be of the sinensis strain or some of the many hardy species, is in all cases preferred; but I think that failure is not so much the result of the age of the seed as the conditions under which it has been kept. That seeds may be kept under certain conditions for any length of time without losing their original vitality may be amply illustrated if occasion requires. At present, however, I will only call attention to one or two cases—first, of seeds buried in the earth at 3 feet deep; secondly, of seeds in packets, kept for a number of years; and, thirdly, of others sown as soon as ripe. A case in point of the first instance was brought under my notice some few years ago by Mr. Latham of the Birmingham Botanical Gardens. who, having occasion to supply fresh soil to one of the sickly specimens of the Fir tribe, opened a trench 3 feet deep, at which depth a hole was made under the tree, and a seed pan filled with the soil was taken out, watered, and covered over with glass to prevent anything falling on to it. In a few days signs of life were apparent, and ultimately some thirty species, mostly weeds, were counted. On inquiry, Mr. Latham discovered that the tree had been twenty-seven years planted, and that a quantity of old potting soil had been used in planting it. This shows clearly that the two great essentials, light and heat, were absent, the seeds at this depth remaining uninfluenced by external conditions. The second instance is that of Primula seed, the species in question being *P. verticillata*, which, after having been placed among others in a box for several years wrapped in newspaper, germinated at the rate of 95 per cent., and this in less than three weeks after sowing. A quicker result could hardly be expected from seed of a current year's crop. I have, however, had a good crop of seedlings of *P. sinensis* from seed sown as soon as dressed in about three weeks from the date of sowing.

The third case is that of *Omphalodes Luciliae*, which is particularly slow in vegetating. I have sown seed of this as soon as ripe which has taken two years to germinate, and of its ripeness there can be little doubt, as I always left the seeds till ready to fall before I collected them. Instances, too, have been recorded of old Cyclamen seed having vegetated several days before the new seed, both having been sown at the same time and treated alike, so that it is not policy to discard seeds of valuable plants too readily. Palm seeds, and seeds generally of an oily nature, are best sown as soon as ripe, and even these in some species are very slow in germinating. Anyone desirous of keeping seeds of choice plants may do so either by placing them in bottles tightly corked, or in oilskin paper, both very simple and effectual. It is the constant exposure and varying changes of atmosphere, sometimes hot, cold, dry, damp, and so on, which cause seeds to lose much of their original vitality, and which are, as a consequence, almost valueless.—E. J.

SHERWOOD LODGE.

AMONGST the many charming residences of the picturesque forest of Sherwood is Sherwood Lodge, the Nottinghamshire seat of Lieut.-Col. Seeley, M.P., which is delightfully situated, and commands an extensive view of the surrounding neighbourhood. When entering the grounds a visitor feels isolated from the busy world, although but a few miles from several of the most extensive collieries and ironworks in the midland counties. Although a comparatively new garden, it is well worth a visit from any enthusiastic horticulturist, who, if he does not derive much pleasure and instruction thereby, must be singularly deficient in his powers of observation.

The mansion is built in the Elizabethan style, and is of moderate dimensions. It is closely surrounded by noble trees and shrubs of luxuriant growth, and is well furnished with a choice collection of climbers, amongst which we noticed *Clianthus puniceus* in flower. Attached to the house on the south side is a very pretty conservatory (built by Messrs. Messenger of Loughborough), and it contains, amongst other good plants, a remarkably fine pair of *Dicksonia antarctica*, planted out, the head of which measures about 20 feet across. The roof is lightly drooped with *Lapagerias* and other climbers, whilst a pretty fountain occupies the centre of the house. At one end stands a pair of *Araucaria excelsa*, the side stages being devoted to various small flowering plants, amongst them being some fine Cockscombs.

Sherwood Lodge is noted for its fine collections of Conifers and other trees and shrubs. Though the soil in many places is poor, much of the success attending the growth of these is due to the care and attention of Mr. Swanwick, the able gardener, who has spared no trouble in draining and improving the soil where the more delicate kinds are planted. The pleasure grounds are charmingly situated on a gentle slope, terminating in a valley, from which arises on the opposite side another slope of equal extent. They are laid out in a picturesque style with much boldness of design. Broad expanses of open, well-kept lawns and walks, with graceful flowing curves, noble Elms, majestic Oaks, and spreading Cedars, attract

the eye when we stand in the front of the mansion. Very little bedding-out is practised, but what is done is simple and effective. Each side of a long twining carriage drive is judiciously planted with a number of beautiful trees, such as *Picea lasiocarpa*, *P. Pinsapo*, *P. grandis*, *Pinus Coulteri*, *Abies Douglasii*, *A. brachyphylla* carrying a number of fine cones, *Araucaria imbricata*, and many perfect specimens of Golden and Silver Hollies and Yews. There are many noble Beech and Elm trees, whilst in various parts of the grounds are placed large variegated Aloes, which impart a very pleasing appearance.

The kitchen garden is situated to the right of the mansion, and has two great disadvantages, in having no walls and a north-east aspect. Notwithstanding these drawbacks, Mr. Swanwick manages, with the exercise of much skill and attention, to produce excellent crops of both fruit and vegetables. The Beet, Onions, Celery, Cauliflowers, &c., were excellent. Asparagus is well grown. Apples and Pears are grown on the espalier principle, and adorn the margins of the principal walks, and are carrying heavy crops of excellent fruit.

The glass houses are numerous, but not extensive. They are mostly old, and have not the same appliances as modern erections. Notwithstanding this, Mr. Swanwick grows both fruits and plants well, and is a very successful exhibitor at many of the leading horticultural shows in the neighbourhood. The stoves contain a good representative collection. Allamandas and Bougainvilleas are well grown. Several huge specimens are at the present time profusely flowered, whilst others have already played their part. Plants for table decoration are largely grown, and special attention is paid to them. The following are a few of those most esteemed—*Crotons Warreni* and *interruptus aureus*; *Aralias gracillima*, *Veitchi*, and *regina*; *Dracenas Ernesti*, *nigro-rubra*, and *Sydneyi*; *Cocos Weddelliana*, *Geonoma gracilis*, *Areca Baueri*, and *Pandanus Veitchi*, are a few of those most largely employed. Another house contains some good Queen Pines around the side beds, whilst the centre is devoted to a general collection of useful stove plants, amongst which are some well-coloured *Crotons* and a healthy plant of *Anthurium Andreanum*. The vineries contain a good average crop of well-finished Grapes, *Gros Guillaume* being especially noticeable. Other houses contain a number of *Azaleas*, *Camellias*, and other winter-flowering plants. General good order prevails throughout every department of the garden, which proves Mr. Swanwick to be one of our most able horticulturists, and his courtesy is as marked as his undoubted ability.—J. H. WALKER.

EARLY PRUNING VINES—LAYERING VINE RODS.

MR. IGGULDEN'S letter on the subject of cutting bunches of Grapes is timely, and will be of service to amateurs and diligent readers of the Journal like myself, if it should elicit the opinion of recognised authorities on Grape culture. It is a question that has been exercising my mind for some weeks past. I cannot help thinking it a mistake to cut off the foliage while still grass green, in the wholesale manner that must prevail when the bunches are cut with a portion of the lateral, and I am intending, for my future guidance, to mark my Vines and observe the effect next year on the produce from spurs where the laterals have been so shortened as compared with those left at greater length until the leaves have fallen.

May I also say a word on your reply to a correspondent (who is about to enlarge his vinery) on the subject of pegging down the stems? You may be, and probably are right in advising him not to do it. My experience, however, is in favour of the practice, particularly in the case of Vines where the roots can easily run away from the prepared borders.

My Vines have been planted eleven years; the borders inside and outside were all made but not confined. The Vines are vigorous and annually produce heavy crops of good fruit, and I have consequently never troubled about the roots. They are grown on the extension system, and some of the Vines have half a dozen main rods.

Two years ago, in order to get a rod into a more convenient position, I pegged it down in the borders just within the house. Roots were at once made, and this year the berries on the bunches on that particular cane have been far finer than from any other on the Vine, or on any other Vine in the house. I presume the new roots of this cane are all in the border proper, which gets a good annual top-dressing, while probably many of the feeding roots of the others are quite beyond the border. My intention is to treat several other rods in a similar manner next spring.

For the encouragement of brother amateurs I may say, that although confined to the desk every day until five o'clock, I manage, with assistance only in thinning the berries, to grow annually about 500 lbs. of Grapes, and sixty to seventy dozens of good Peaches and Nectarines—plenty of work, but a "labour of love."—E. BROWN, *The Grove, Lincoln*.

[We are well aware of the advantage that often results from layering Vine rods, but every case must be judged on its merits, and there is danger of overcrowding resulting from great luxuriance in a very small house. We have this year observed most satisfactory examples of layering Vine rods by Mr. Bardney at Norris Green, who has made weak Vines strong by that method, and in the place of a light crop of small Grapes produced a heavy crop of first-class fruit;

but with Vines strong to begin with, and the roots working freely in a new border, it by no means follows that layering the rods would be advantageous, and especially where there is little roof space for the growths to cover. We congratulate our correspondent on his success, and are glad to publish a letter so encouraging to amateurs.]

MALT AND KILN DUST.

WILL you allow me to correct a slight mistake in one of your answers to correspondents—"Vectis"—in last week's Journal. You state that malt dust is not the root growth of the Barley in process of malting, but is what passes through the kiln perforations whilst drying. This is not so. Malt dust is the root growth of the Barley screened from the finished malt after it is thrown from the kiln, and is a valuable food for cattle. That portion of the rootlet which passes through the kiln floor in the turning of the malt, and which is mixed with the dust from the fire, is termed kiln dust, an excellent and most valuable manure, much sought after by gardeners and farmers.—JAS. BARTLETT, *Warminster Brewery*.

[Our correspondent is quite correct, the word "malt" was accidentally inserted instead of "kiln." We have used both malt and kiln dust for the purposes indicated, and found both very good.]

CULTURE OF HYACINTHS IN BEDS.

It has now become quite general in both large and small gardens to have one or more beds of Hyacinths out of doors, and very welcome their flowers are in the early spring before the beds are needed for summer plants. A few hints upon the subject may therefore be useful, especially as planting time will soon be here, and bulbs should be procured at once.

SOIL.—To grow Hyacinths well in beds the soil should be rich, light, and deep, supposing the soil of the garden is a sound loam and well drained. Then fix upon the beds intended for these bulbs and excavate it to the depth of 15 inches. Level the bottom, and place a layer of small stones or brick-ends broken small, 2 inches thick. Cover this drainage with 2 inches of littery dung; then mix the soil that has been thrown out with some well-decomposed cowdung, some leaf mould, and plenty of river or sea sand, well screened. The proportions to be one part cowdung, one part leaf mould, to six parts of loam. Should the substratum be clayey or gravelly, that part must be wheeled away and as much good loam added as will replace it; then mix the compost well together, and fill the bed with it; let it be 4 or 5 inches above the former level, to allow for settling; lay it perfectly level, so that it may have the full benefit of the rain that falls upon it. This preparation of the beds should be done immediately. If there is time it would be all the better for a turn over before planting. I may just remark that if cowdung cannot be procured hotbed dung well decayed will do; but I greatly prefer the former, because it is of a cooler nature, and, generally, has less straw amongst it. I have used cowdung gathered out of a pasture with capital success.

PLANTING.—The best time for planting is the first week in October, though if the weather is mild they may be planted as late as the middle of November. Much depends upon the weather and the state of the ground. It should by all means be moderately dry, and therefore it is better to wait a week or two should the season at the right time of planting be wet. To prevent treading upon the bed at that time lay upon it a narrow piece of board long enough to reach across it, or have the board strong enough to bear the planter's weight, and raise it up at each end high enough to clear the bed; then procure a dibber to plant them with, which should be thick enough to make a hole as wide as the largest Hyacinth is in diameter, and the end that is thrust into the soil should be cut across and a mark made just as far from the bottom as the bulbs should be covered with soil; the proper depth is 3 inches from the top of the bulb. Anybody with a saw and a knife could make such a one. Having a fine day and the board and dibber ready, then bring out the bulbs and place them on the bed just where they are to be planted. Each Hyacinth should have at least 5 inches to grow in, but 6 inches would not be too much space for the leaves to expand, especially if the same bulbs are to be planted again the following season. If the colours are to be mixed place them so that the colours will succeed each other in rotation, as, for instance, 1, red; 2, blue; 3, white; 4, yellow; then 5, red, and so on till the bed is full; or if there are several beds, and it is desirable to keep the colours separate, so that one bed shall be red, another blue, another white, and another yellow, then plant them accordingly. For a geometrical flower garden the latter mode will be preferable. As soon as one bed is placed with bulbs, then fix the board across at one end, and proceed to plant them. As the planting proceeds have some of the compost ready sifted through a coarse sieve, and fill up the holes with it. This is much better than levelling the holes with a rake, because they are when so covered sure to be at the right depth. When all is planted, then rake the bed very lightly, and the operation is complete.

SHELTERS.—The Hyacinth is hardy enough to bear a moderate degree of frost; but it is advisable to cover the bed with about 2 inches of spent tanners' bark, to be removed early in spring before the shoots appear above ground. Where this is scarce, half-decayed leaves would answer the same purpose, or a mat or two thrown over the bed would be protection sufficient. These shelters are for such Hyacinth beds as may be in an ordinary flower garden on the lawn, or in beds in a geometrical flower garden, with Box or other edgings and gravel walks. If an amateur or florist cultivates the Hyacinth in long common beds like Tulips, a per-

manent shelter should be put up in the form of the bed, or the beds might be sheltered with hoops and mats. These kind of shelters can be used when the bulbs are in flower as a protection from sun, wind, and heavy rains. If so protected, the season of bloom will be considerably prolonged.

WATER.—As the season of the Hyacinth's growth takes place during winter and early spring it very seldom happens that they require much water at the roots, but during dry parching winds which sometimes occur in March, a slight sprinkling over the beds will be acceptable to the rising buds. In frosty weather this should be applied in the morning only; but if there is no appearance of frost, then water in the evenings also, previously to putting on the shutters for the night. This sprinkling may be continued with advantage till the blooms begin to expand. As soon as the bloom is over the old flower stems should be cut off, but not quite down to the ground, the covers removed, and as soon as the leaves turn yellow the bulbs should be taken up and laid upon a mat to dry. By being laid upon a mat they can be lifted easily under shelter in heavy rains, which would injure them much if allowed to fall upon them. When the leaves are all quite decayed dress them off carefully, without bruising the bulbs, and then put them away in a dry cool room till the planting season comes round again.—T. Y.

KITCHEN GARDEN.

WEEDS.—These always appear very plentifully in kitchen gardens at this season. Those which were allowed to bloom and seed in the fore part of the season are responsible for the abundant crop now, and we could not point to anything more convincing as to the evil and mistake of allowing weeds to seed than the trouble experienced with those young weeds now. In the hot weather it was easy matter to run the Dutch hoe through them, and they would die in a few hours, but now that the soil is moist and the atmosphere cool, hoeing has almost lost its advantage. After hoeing, the rough of them should be raked off. Should they persist in growing, hand-weeding must be resorted to, and this is both tedious and expensive, but it only tends to still further illustrate what we detest, the folly of keeping a dirty garden. If allowed to go on now the weeds will destroy autumn-sown Onions, Spinach, &c.

LATE POTATOES.—We are pushing on with lifting these. Nothing can be gained by allowing them to remain in the ground now. Choose fine days for taking them up, and get them under cover as soon as possible. Many complain of their late Potatoes not keeping well, but this cannot be expected unless they are treated properly at lifting time. Many think if they only escape disease when stored it is all right, but in our opinion Potatoes stored while damp have never the same excellent flavour as those placed in quite dry. Too much importance cannot be paid to this. So long as they are dry and in the dark there is no danger of their deteriorating in any way. Webb's Improved Schoolmaster is the best of all our late Potatoes this season. We are digging fine crops now from between rows of Broccoli, and in quantity and size it is excellent, while the sample we cooked the other day were all that anyone could desire. Our Potato supply until the new ones come again is safe.

RHUBARB.—The whole of the leaves on this have nearly disappeared. The crowns are thoroughly well matured, and forcing the roots in November and onwards will be an easy matter. The decayed leaves, however, are no use. They should all be cleared off, and place a quantity of good manure over the crowns. The finest Rhubarb we ever possessed came from roots which were fed more in winter than summer.

CAULIFLOWER.—Veitch's Autumn Giant is now turning in. None equals it in size or quality. It is superb in every way, and is distinct and good in every way. Those who try to substitute any other variety for it make a mistake. It has no equal, and should be grown in all gardens for an autumn supply. The other day we heard someone say they were cutting heads now from plants raised from seed sown last autumn. This is superfluous. We are cutting from plants from seed sown in the open border in March last. Young plants now a few inches high, and being raised for the first supply next spring, should be taken up and planted in frames or under handlights to stand the winter. They must have good soil and a sunny position. We treat a few thousand plants in this way, and numbers are left in the seed rows, where they often keep in good condition and prove very useful in spring. Those put into frames should be kept 3 inches apart, and the lights should not be put over them until there is danger of their being injured by severe weather. Anyone having no handlights or frames, but plenty of Cauliflower plants, should dibble a quantity of them close to the bottom of a hedge or wall where they will be slightly protected. Should a severe winter be experienced, break the leaves over recently formed heads when frost is expected.

TOMATOES.—Early frosts soon injure these, and as they are too much valued to allow them to be spoiled for want of attention, frame lights should be stood up against those growing on walls. We cut ripe fruits in November last year through adopting this simple plan in time. As soon as the fruits become in the slightest way coloured, cut them at once and place

them in a warm dry room to ripen. They will lose nothing in flavour by this. Where fruits are very abundant they ought to be taken to the kitchen and converted into Tomato sauce. We had lately some plants growing in a cool pit on which a heavy crop had just formed, and as these were growing in pots they have been moved into square boxes a little larger than the pots and placed in a warm Cucumber pit. Others have been put up on the back shelf of a Pine stove, and we feel pretty sure of having plenty of ripe fruit to the new year at least.

LETTUCE AND ENDIVE.—Neither of these is quite hardy, and it is always a safe and good plan to have a quantity of them in frames to keep up the supply when those in the open fail. Plants about half grown in the open quarters now should be lifted with good balls of soil attached to the roots, and be planted in cool frames 10 inches or so apart each way. They will soon become established and grow large, and be more useful than those which may be lifted and stored away when fully grown. Store Pea sticks, which will be of service next year. Clear out places ready for storing Carrots, Beetroot, &c., and do not allow any useless vegetables to remain growing.

FRUIT FORCING.

FIGS.—*Early Trees in Pots.*—As soon as the early Figs in pots have cast all their leaves the trees should be pruned, well washed, and properly dressed preparatory to tying them in to new stakes. If repotting is considered necessary, no time should be lost in getting it done and everything made ready for a new start. The Fig, unlike many other kinds of fruit under pot culture, seems to become prolific in proportion to its age, every short spur being literally covered with embryo fruit ready to start into activity when heat is applied to the trees. In course of time the trees become too large for removal from the house, as, for instance, when they are in 18 or 20-inch pots, in which it is best to leave them on the permanent brick pedestals, and build solid walls of new turf and old lime rubbish round each pot from the base of the pedestals to the rim of the pots, which should be done so soon as the trees are cleansed and tied. When the time arrives for forcing, fermenting Oak leaves and fresh stable manure well worked together should be used for filling the pit. This soon draws the new roots into the turf, and more turf should be added as the roots show on the surface, and the mass being properly supplied with liquid manure, the trees will scarcely lose a fruit when the change takes place for ripening, besides the steady growth which the cramming and high feeding induces results in a steady succession of fruit throughout the early spring and summer months.

Succession Houses.—Permanently planted trees will now be sufficiently advanced for lifting and replanting where they are too strong and show an inclination to make gross unfruitful wood. When dealing with these trees the principal points are—good drainage, rough calcareous compost, and firm ramming to insure the even passage of water.

Late Houses.—The trees in these are still producing good fruits, but they must now have the water supply lessened or withheld, encouraging them to ripen up the wood and go to rest. The house should be kept well ventilated constantly, but if the wood does not ripen kindly, allow the temperature to rise to 80° or 85° from sun heat by closing early, and before nightfall admit sufficient air to insure a circulation.

PINES.—As a fermenting material tan is the best heating medium for the roots of plants such as these, and where it can be procured at a reasonable price it may be considered the most effective, indeed superior to others for this particular purpose. In the case of rootless suckers it may be solely used as the means of artificial heat, especially for bottom heat, and for succession as well it has no equal. Beds composed of this material occasionally require to be renewed by an additional supply of fresh material about this period, and this should be attended to at once before the season is too far advanced and too precarious for such operations to be safely performed. The effect resulting from 12 to 18 inches of fresh tan being well worked into the rest will be the production of sufficient warmth to afford new life for a considerable period onwards, and without the danger of its being afforded too profusely. This is also the proper time to make new tan beds, which in the first instance should be made 3 to 4 feet in thickness. The tan for this purpose should be prepared by laying it in a shed dry and airy, where it can be turned over a few times, as it by that process becomes drier, and the risk of violent heating is to a great extent diminished. When made into the beds daily supervision must be made of the beds, or much mischief may happen at the roots of the plants plunged therein before it is discovered. The season is so advanced that artificial heat must be steadily increased. Although we do not advocate a high night temperature, sudden transitions in temperature are to be deprecated at any season. For rooted suckers 55° to 60° at night will be sufficient to keep them gently moving, 60° to 65° for successional plants, and about 70° in the fruiting compartments, with 10° to 15° rise from sun heat.

CUCUMBERS.—The first batch of plants which were raised from seed sown about the second week in August have nearly covered the trellis with short-jointed wood, and are showing fruit freely. These, however, provided the supply from other sources is equal to the demand, and there is ample scope for root-action, should be removed forthwith to enable the plants to thoroughly establish and strengthen themselves for producing and maintaining a supply of fruit about Martinmas onwards; but on the other hand, where the roots are confined to pots or boxes and are filled with roots highly fed, one or a couple of fruits per plant should be allowed to swell and so prevent the stored or pent-up sap from becoming stagnant and disease result. Ventilate the houses freely on all favourable occasions, so that they may make a short-jointed and consolidated growth, which will, all other points duly attended to, enable them to pass through the

igour of winter satisfactorily. Avoid cold draughts, and husband sun heat by early closing.

Where there is a second house the plants from seeds sown at the close of August or early September will have reached the first wire of the trellis, to which they will need to be trained in the usual course. Add more soil to the hillocks, as the roots protrude through the surface of the soil, and afford water when necessary. Those in pots and boxes will need a copious supply frequently. Attend to the stopping, thinning, and tying of the shoots as necessary. Maintain a genial condition of the atmosphere by syringing early on bright afternoons and damping available surfaces two or three times a day. Should green or black aphides be troublesome fumigate with tobacco paper of good quality moderately a couple of evenings in succession, when the foliage is dry, being careful not to give an overdose, which will prove highly disastrous if not fatal.

PLANT HOUSES.

Calla æthiopica.—Where a system of planting out has been practised these must be lifted and placed into pots at once. It is a great mistake to leave them in the ground until early frosts compel them to be lifted and housed. They become established in their pots much earlier outside than under glass, unless there is special provision for them. It is not necessary to lift the plants with large balls of soil attached, but as many fibry roots as possible should be retained. The greater part of the soil may be removed from the roots so that they can be placed in from 6 to 10-inch pots according to their size. Strong plants can be accommodated in the smallest size, and these are most useful for decoration. A few large crocks only are needed at the base of the pots for drainage, and the plants should be potted in a compost of good loam and decayed manure, about one-third of the latter may be used with advantage. After potting, well soak the soil with water and syringe the foliage for the first week. If this is done, and the plants stood in a shady position, they will soon commence rooting afresh, and in about a fortnight will be ready for housing in any cool airy position. They should, however, be left outside as long as the weather remains favourable.

Solanums.—The varieties of *Solanum capsicastrum* that have been planted out must also be lifted. Only reduce the ball of soil sufficiently to allow of placing them in suitable pots. If lifting and potting is not done carefully the foliage of these plants is very liable to turn yellow, and when this takes place their value is destroyed. The healthier and darker the foliage can be retained the more beautiful are the plants. This can be accomplished by careful treatment after lifting and potting. The soil and their foliage must be kept thoroughly moist, even a dry atmosphere must be avoided until the formation of fresh roots, when they may be gradually removed to a lighter and more open position until it is necessary to place them under glass. Plants that have been plunged in soil, ashes, or other material can now be lifted, removing all the roots that are outside the pots. Afterwards give the same treatment as advised for those that have been planted out; no injury will then result from the removal of the roots, and the foliage can be retained in a healthy condition.

Bouvardias, *Salvias*, *Eupatoriums*.—These and similar plants that have been placed out during the summer should be lifted and established in pots ready for housing at the approach of frost. They soon establish themselves in a shady position outside if given the same treatment as advised for *Callas* and *Solanums* until they commence rooting freely. When lifted and stood together they are much more readily protected from slight frost than when growing in the borders outside. Do not remove them indoors until established, and in case of frost they can easily be placed on their side and covered with mats or tiffany. Slight protection like this is ample, and allows of the plants being left outside longer than would otherwise be possible.

Lilacs and *Guelder Roses*.—Where these are retained in pots and forced every alternate year they will now possess bold prominent flower buds on moderately strong growths. Some of the terminal buds of the former are showing signs of starting again into growth, which frequently is the case when heavy rains or frequent showers follow long spells of hot dry weather. Growth was brought to a standstill early in the season, and to preserve the buds in good condition the plants must be lifted from the soil in which they are plunged and all roots outside the pots removed. This will check the plants sufficiently to prevent further growth.

THE FLOWER GARDEN AND PLEASURE GROUND.

Lifting Old Bedding Plants.—While the beds remain fairly bright and ornamental some diffidence is felt in lifting any old plants that may be required for stock purposes, but if they cannot be had from the mixed borders they must be taken from the flower garden before they are injured by frosts. If a sufficient number of cuttings of such kinds as *Coleuses*, *Alternantheras*, *Iresines*, and *Heliotropes* have not been struck, an attempt must be made to pot up a number of old plants, and these if safely wintered will afford abundance of cuttings in the spring. Only small balls of soil should be taken up with the roots, especially when the soil in the beds is rather heavy, and clean well-drained 5 inch and 6-inch pots are quite large enough for any of them. All should be placed in a warm frame, pit, or house, and shaded from bright sunshine for a time. These lifted plants must be very carefully supplied with water, and the three first named are best wintered on shelves or stages in a forcing house. The *Heliotropes* may be kept in a warm greenhouse. Dwarf *Lobelias* are best propagated in the spring by division of stocky old plants, these sturdy little plants thus easily obtained being of much better habit

than the best of seedlings. A considerable number of plants well furnished with growing shoots may well be lifted (as there is almost certain to be a number of losses), and these each with a fairly good ball of soil and roots may be packed thinly in ordinary shallow *Pelargonium* boxes, using good loamy soil. They may be stood in a shady position for a time, or be placed in a cold frame or pit. A cool dry house or a pit in which heat is turned on in either very damp or very frosty weather best suits them during the winter, both excessive heat and dryness, or cold and damp, being most injurious. Choice variegated and Zonal *Pelargoniums*, of which the stock is limited, ought also to be potted, every uninjured shoot, if preserved during the winter, being available for striking early in the spring. No attempt should be made to secure a ball of soil, but care should be taken to damage the roots as little as possible. They may be placed singly in 3-inch pots, or five or six plants may go in an 8-inch pot. When they are thus crowded together it is advisable to pick off the bulk of the old leaves, as these are liable to damp off and spread decay all round. Supposing the plants are given fairly moist and good loamy soil, but little water will be needed, especially if they are stood in a cold house or frame. If placed at first in a slightly heated pit they will recover more surely and quickly from the check received.

Begonias.—When the beds are broken up before a severe frost has been experienced, these are frequently still blooming freely. All will lift readily, and when carefully potted and stood in a shady position, either in a conservatory or greenhouse, they will continue to bloom for some time longer. *Begonia weltoniensis* lifted from the beds are very effective for a time, and the same may be said of the tuberous varieties. None of them should be kept very dry when at rest, nor, on the other hand, must they be stood under the drip of various plants on a staging overhead. If the tubers are left in the ground later than October many of them are liable to decay during the winter, but we have seen them wintered in the open ground, the position in this case being warm and the soil of a light nature.

Propagating Shrubby Calceolarias.—Shrubby *Calceolarias* have been surprisingly bright and effective this season, but cuttings are rather scarce. Fortunately they will strike if put in any time during October and till late in November, but it is not advisable to defer propagation very late or severe frost may spoil the cuttings. A cold frame or pit is the best place for striking and wintering the cuttings, and if a heated pit is used the heat in the hot-water pipes should be turned on in frosty weather only, the aim being to keep the plants alive but not in active growth. A fairly dry and well-drained position should be selected for the frames or handlights. No heating material whatever should be used, but the frames may be stood on a shallow firmly built bed of spent manure and leaves, more of this material being placed in the bottom of the frames; on this to be put about 6 inches of fairly good loamy soil, finishing off firmly and evenly with half that depth of light sandy soil, a surfacing of sand completing the bed, and this should bring back the cuttings when inserted to within 6 inches or less of the glass. Hard "wiry" cuttings are not suitable, and the preference should be given to those that are flowerless, short-jointed, and fairly but not over-succulent, and they should be trimmed and put in at once. All should be about 3 inches in length and cut to a joint, the lower pair of leaves only being trimmed off. They may be dibbled in about 3 inches apart each way, every cutting touching the bottom of the hole made and firmly fixed. A watering through a fine-rose watering pot to be given, and the frame, pit, or handlights, as the case may be, kept close and shaded from bright sunshine till the cuttings are rooted, this taking from six weeks to two months to accomplish, after which time they should receive abundance of air on all favourable occasions.

Gazania splendens.—Cuttings of this good old-fashioned edging plant may be put in at the same time as the *Calceolarias*, and in precisely the same manner, but in this case spring-struck cuttings are equally as good for bedding out as those struck in the autumn. Consequently only half the required stock need be struck now, and these will furnish a number of good tops in the spring, which will strike readily in a little heat.

Dahlias.—Only the best of the seedlings are worth preserving, and these should be marked before frosts cut them down. All the sorts, if not correctly named, should be labelled, in order that their respective heights and colours may be known in the spring. When the soil is of medium texture and the plants not too large they may sometimes be safely potted. If the attempt is made to secure a large ball of soil and roots large portions are apt to break away, and failure is the result. We have frequently succeeded in establishing large lifted plants in 12-inch pots, and these, after being stood in a cool shady position for a few days, have been transferred to a conservatory, where they continue to flower till *Chrysanthemums* are abundant. *Constance* or the *White Cactus* lifts fairly well, and the blooms thus secured are of great service. *Juarezii* is apt to grow too large to be lifted safely, but the smaller and very showy *Glare* of the Garden is well adapted for pot culture.

Marguerites.—These also can be readily potted, and if kept shaded from bright sunshine for a time will continue to blossom for some time longer. They are very stocky this season, and are more floriferous as well as more easily lifted accordingly.

AMERICAN BLACKBERRIES.—I believe Mr. Muir is right in his estimate of the value of these. The Parsley-leaved Bramble has been growing in the garden here for some years, and annually produces a good crop of fruit, which I consider decidedly inferior to that of the common Bramble growing about the place. This variety is worth growing as an ornamental

plant. A large bush of it trained to a few iron stakes has a very pleasing effect. Visitors scarcely ever fail to notice our plant. After the glowing accounts given of some of the newer varieties we planted some of Lawton, that being recommended as a good variety, but it turns out to be no better in quality than the Parsley-leaved Bramble, and without the ornamental foliage of that variety.—E. B.

THE BEE-KEEPER.

USEFUL HINTS ON BEES.

SYRIAN BEES.

THE Syrian bees have some good qualities, and but for their spitefulness and tenderness during cold weather would prove a good variety of bee. Like the Cyprian crosses the Syrian ones crossed with the Carniolian drone have already proved themselves good honey gatherers, and, as is usually the case with crosses, partaking of the nature of the male, and are therefore very docile. The pure Syrians I observe are capital sealers of their honey; they do not, like some varieties, have much loose honey in their hive. These good features palliate their stinging propensities, which I am inclined to think climatic influence will lessen. It is premature to speak on that point positively, but my experience with several indicates it. Where there is a will there is a way, so I find there is a way of manipulating the Syrian bees, as there is with others, by "flinging a bone in the devil's teeth." While manipulating several hives of pure Syrians lately I was savagely attacked by them, but having my knife in hand cut a piece of their honeycomb. Their propensity for honey being so great they at once ceased the attack and flew to the honey, when I was allowed to have my will while they had theirs. I have more to say about these Syrians, but wait till I have more data.

THE HEATHER HARVEST.

Owing to the continued low temperature, the honey harvest from the Heather this year will not be great. Favoured localities may have yielded a fair quantity, but in many it is nil. In the south of Scotland I hear of 50 lbs. being stored, but in the north it is a failure. From statistics I should say the average gathering throughout Scotland will not exceed 15 lbs.

CONDEMNED BEES.

Where surplus bees were utilised in July and then joined to others, they will have served the purpose of gathering much surplus honey to their master, and now there will be no condemned bees to dispose of; but where this was not attended to there will be some. There are two ways of putting these to use. The one is to put a swarm on to another stock hive, thereby strengthening it; but this system of joining, particularly when done in the usual haphazard way, has its drawbacks, because unless both queens are young the old one may be the one saved. Therefore, care should be exercised to depose the most worthless queen, and otherwise use every precaution for the safety of the most youthful and prolific of the two.

Manipulating bees so late in the season is not only difficult but liable to cause fighting and robbing, so every care should be taken to guard against it. Manipulating within doors is not always practicable. When that cannot be done the operator should either have a portable tent to place over the hive, or have in readiness a cloth to cover the hive at any time bees are observed about.

Searching for the queen being the principal object, a spare hive should be provided, also a case having glass on both sides of the proper width and depth for frames, and a ventilating lid. Into this case drop a frame with combs and bees from the hive the queen is wanted. The moment the frame is removed protect it from robbers, and search for the queen on the frame in the glass case until she is found. When the queen is not found on the first frames examined,

lift it into the spare hive, protecting it also from robbers by cloth coverings. This case is fixed in a frame of such a height that the bee-keeper may not have to stoop when searching for the queen. There is sometimes a difficulty in catching the queen from a straw hive where the bee-keeper wants experience. A very simple plan to make this easy is to have a race made with wood on one side and glass on the other, and about an inch between, having two slides to stop the passage and imprison the queen when she is observed. This race requires to be attached to a board covering the hive when inverted, the race leading into an empty one into which the bees ascend when being driven; but it is better that the whole thing be fitted to a frame made for the purpose. A practical bee-keeper does not require such tackle, but to a novice it is not only useful but interesting. A second and good plan of utilising condemned bees is to give them comb foundations to work out for next season's use.

YOUNG QUEENS AND QUEENS IN RESERVE.

Not only should bee-keepers study to have young queens at the head of all stocks, but should keep a few in reserve in case of any casualty occurring in any of the hives. If not wanted for that purpose they are useful for putting at the head of the stock swarmed next summer or to sell.

SMALL SUPERS.

Those who can sell supers readily should now set to work and have them in readiness for next year. The market here is glutted with sections, but there is a demand for well-filled small supers.

COVERING HIVES.

I again advise covering the crowns of all hives well with meadow hay or sphagnum, pressed firmly, but not covered with any material unless the roof, which must admit of a free circulation of air over the top of hay. Avoid placing non-porous material on the top of the hay.

GENERAL REMARKS.

See that all hives have a full supply of meat to last till May. Protected against admitting wet from outside as well as being protected from condensed moisture inside through too much contracted doorways, or in the absence of a ventilating floor. In windy situations guard against the hives being blown down by a wire pegged to the ground and fastened to a screw-head in the side of the hive. Plenty of good security against storm and being kept dry are the secrets of success, if I add let them alone until the spring.—A LANARKSHIRE BEE-KEEPER.

"LABOUR LOST—A PROTEST."

MR. THOMAS WILDMAN, after he had given some instructions as to the proper management of bees, concludes the chapter in words which were intended to parody the reply, as he tells us, of C. F. Cresinus when arrayed before the Curule Edile. "These, Britons! are my instruments of witchcraft; but I cannot show you my hours of attention to this subject, my anxiety and care for these useful insects; nor can I communicate to you my experience, acquired during a course of years." Very true is the impression here conveyed. We can teach, if neighbours show those who desire demonstration, and by other means we can assist others to attain that measure of success to which we have ourselves attained, but we cannot relieve them if we would of anxiety nor after-attention which a careful management necessitates. We cannot give them that practical experience so necessary to prove the value of the teaching we desire to inculcate; but if only those who desire to obtain assistance will strictly carry out the instructions given them in the articles in various books and periodicals, the result will be that a success, probably greater than their most sanguine expectations lead them to hope for, will follow from an experience gained by putting theory into practice, and proving by actual experiment the truths they are in their novitiate obliged to accept, not being in a position to refute.

Here lies the essence of the advice I desire to give, for there is evidently great need for an emphatic protest against the course taken by so many of our friends who are desirous to learn from the *Journal of Horticulture* and the *Bee Journal* the way to manage their apiary and to conduct the different operations necessitated by the possession of a few stocks of bees, if the greatest amount of pleasure and of profit is to be obtained from the study and care of these insects. To give an instance: Our country friend desires to unite the bees driven from a stock to the one standing by its side. He accordingly refers to back numbers of this *Journal*, and

finds exactly what he requires. He reads the instructions most carefully through, and proceeds to put them into practice, but as "the town" is some distance away he has no essence of peppermint or other strong-scented substitute, so forgetting what he has read about the different odours peculiar to each stock, he reckons "it doesna' matter," and thinking to get done in good time, about four o'clock in the afternoon he proceeds to unite. An hour makes no difference, and as for that "bit o' essence" it will matter nothing he seems to think—and in skilful hands it might not be of much moment. In other respects he carries out the instructions, but is amazed in the morning to find that a serious fight has taken place, and that thousands of bees lie dead upon the floor, and that instead of his stock being strengthened by the union, it is reduced to a most deplorable plight. Everybody knows the sequel. Hot abuse and vituperation of new-fangled ways of books and book-learning, vows never again to venture out of the ruts of custom into the paths of knowledge. He never blames himself for omitting the essence. No he. He never thinks that evening is the time when he is told to perform the operation; but thanks the person who was kind enough to instruct by abusing him and all his ways. This is no exaggeration. It is in one form or another of far too frequent occurrence. Let me ask, is it fair? In the name of common sense is it reasonable, first of all, to neglect instructions, then abuse the instructor when failure follows the departure from the rules given for guidance at such times?

There is no more common abuse prevalent—not only amongst bee-keepers, but amongst gardeners and other classes—than this, shall I say impertinent misuse of books. Books and papers are written to instruct. Some use the instruction; many abuse it. Few are so clever as to need no instruction. More there are who are ashamed to acknowledge ignorance, and many are to be found who may, if they will to do so, gain from the writings of others a knowledge of the subject they wish to understand, which even if it be but a poor apology for practical knowledge, is still a great assistance and a material help when, instead of years, but a few months only can be spared to gain an efficient idea of how to manage even so apparently simple a business as bee-keeping. It is in such cases that a feeling of despair comes over the minds of those who, at no little trouble to themselves, try to assist others. How many times does "A Lanarkshire Bee-keeper" draw attention to the most salient features conducing to success, and yet getting up from reading this advice, and going to some cottage bee-keeper who reads his Journal regularly, there seems to be an absolute determination not to take advantage of the excellent opportunities offered for improving the value of his stocks and doubling and trebling their annual yield? On the other hand, how gratifying to see the result as shown in the apiary of a wise man who, following the teaching he thinks most profitable, carries it out until he feels able by experience to improve upon the teaching he has followed, and at last is able not only to manage his own hives, but to give sound advice to those around him.

Five hundred years of bee-keeping will teach some men nothing, while as many days will give others a knowledge of no superficial kind. To conclude, let me ask one and all who come to books or to papers for advice, to carry out the instructions there given *in toto* until they feel confidence in their own power. Then always remember, in case of failure, that it is not the books at whose door the fault must be laid, but at the door of experience, a hard taskmaster, who often requires many failures ere the high road to success is reached, and even then often throws across the comparatively smooth path of the wayfarer obstacles of so serious a kind as to need more than one attempt to surmount them. It is then time to blame instructors when their instructions have been carried out, not in letter only, but in spirit also, and failure has been the result. Condemnation before fair trial disgraces those who utter it, and fails to strike those who do not deserve it. Criticism is indeed a blessing, and is necessary, but to criticise some knowledge of the subject under consideration must be possessed; and as one who feels he is not either better informed or who cannot see some transparent fallacy in the advice given for his assistance, is entitled, before trial at any rate, to deride the means pointed out to him as the surest way of successfully performing a necessary operation.

Men who know most condemn least; those who know little condemn much.—FELIX.

TRADE CATALOGUES RECEIVED.

Thos. S. Ware, Tottenham.—*Catalogues of Bulbs, Daffodils, and Lilies.*
Lambert and Reiter, Trier, Germany.—*General Catalogue of Plants.*
Richard Gilbert, High Park Gardens, Stamford.—*Little Catalogue of One Dozen Specialities.*
L. Jacob-Makoy et Cie., Liège, Belgium.—*Catalogue of New Plants for 1885.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or

members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Addresses for the "Horticultural Directory" (W. L. B. and others).—The information has arrived too late for insertion, and no more names can be added this year.

Lifting Turf (F. T. D.).—It is impossible that questions such as yours, that arrive just as we are preparing for press, can be answered in the current issue.

National Chrysanthemum Society's Show (A Constant Reader).—The prizes named by you, and respecting which you will find more particulars on another page under "Chrysanthemum Notes," will be offered at the Exhibition to be held at the Royal Aquarium, Westminster, November 11th and 12th. There are two classes, and only one prize in each class.

Seakale (E. D. B.).—The roots and crowns to which you refer are raised from portions of smaller roots or thongs, these being cut into lengths of five or six inches in the autumn, stored in soil or ashes, where they form terminal buds, and are planted in the spring. Seakale for forcing is largely grown in market gardens near London.

Caterpillars in Garden (A Ten-years Subscriber).—Though you sent the caterpillars in a tin box it was so bruised below the lid that some of them squeezed through into the letter, and the others were crushed. You may imagine the state of the paper when we state that part of it was almost like pulp. This is through no fault of yours, but the box must have undergone very rough usage in transit. The caterpillar is the larva of one of the Dart moths (Noctua). It is a most destructive pest and difficult to destroy. When Cabbages and other plants are seriously attacked it is often found necessary to dig the soil from each plant and fill in the cavity with soot, and also to place a ring of gas lime or guano round the plants, not close to the stems to form a barrier, the caterpillars travelling from plant to plant at night. Watering the ground with diluted ammoniacal liquor from gasworks has been found serviceable; failing a supply of this a wineglassful of petroleum mixed in a large garden can of soapsuds might have a good effect. Gardens infested with these caterpillars should be cleared of all weeds, and the ground turned up roughly for the winter.

Peaches and Nectarines for Market.—Trellises for Peach House (J. C.).—Market growers have regard to colour and freedom of fruiting, growing a good many Red Magdalen and Royal George, but are guided in the selection of kinds by the time the ripe fruit is required. For early, Alexander, Hale's Early, and A Bec. For ripening in June and onwards, Royal George, Stirling Castle, Crimson Galande, Belle Bance, Bellegarde, Dymond, Violette Hâtive, Barrington, and Late Admiral. Nectarines are not much grown. For early, Hunt's Tawny and Lord Napier, and to follow those Elruge, Violet Hâtive, Pittaston Orange, and Pine Apple. It would be best in a house 10 feet wide to have a low curved trellis to allow of trees being grown in front as well as on the back wall, but the front trellis must not be taken higher than half the height of the back wall, and kept quite 4 feet 6 inches from it, so as to allow of the trees on the back wall having light to their base.

Climbers for Cool Greenhouse (C. E.).—The following will endure a little frost, and will probably succeed in an unheated greenhouse in your district:—*Lapageria rosea* and *alba*, *Solanum jasminoides*, *Passiflora racemosa cœrulea*, *Berberidopsis corallina*, *Clematis indivisa*, with any of the hybrids of the Jackmanni type, *Akebia quinata*. Roses suitable are besides *Marechal Niel* and *Gloire de Dijon*, are *Reine Marie Henriette*, *Cheshunt Hybrid*, *Isabella Sprunt*, *Climbing Devonensis*, *William Allen Richardson*, *Rêve d'Or*, *Perle de Lyon*, *Jean Ducher*, *Madame Berard*, and any other free-growing Tea-scented varieties.

Keeping Late Grapes (W. M. G.).—We are not surprised at the Grapes not keeping, as you state they are not ripe yet. This alone is sufficient to account for their decay, and is a very common defect. Late Grapes, to keep well, should be thoroughly ripe by the middle of September, which can only be effected by assisting the Vines in spring and early summer with gentle fire heat, so as to have them sufficiently early for ripening the fruit by the time indicated. The Grapes should be allowed to hang on the Vines until the leaves have fallen, when they should be cut with a sufficient length of wood below the bunches, to allow of that part being placed in bottles of water, and all the wood above the bunches should be retained, at least it is best so to do, as cuts increase the evaporation. The bottles should be about three-parts filled with clear rain water, and a piece of charcoal placed in each. The bottles should be placed on a rack, so that they slope to an angle of about 45°, so that the bunches will depend clear of the bottles. The bottles will need replenishing as the water wastes, and the Grapes should be examined occasionally for decayed berries, which should be removed as they appear. The most suitable place for keeping the Grapes, failing a Grape-room, is a rather dry room, which can be kept at a temperature of about 45°, or ranging between 50° as a maximum and 40° minimum. The viney is not a proper place, for, if they will not keep on the Vines, they certainly will not in bottles of water in the same house; but the cause of their not keeping is, as before stated, their not being sufficiently ripened, or whilst the sun has sufficient power to develop the saccharine matter essential to their keeping.

Insects on Chrysanthemums (Salopean).—Your plants have been infested with a species of aphid belonging to the *Rhopalosiphum* group or section, and allied to the black species that frequents the Bean and other leguminous plants, though somewhat different in structure and habit. It is probably a species only to be found upon the Chrysanthemum during the

later summer or autumn, the first broods of the insects being reared upon docks and other common weeds. Your method of extirpating them with softsoap and tobacco water is a good one, and something may be done in the way of stopping their migration to the Chrysanthemums, as by the inexpensive means of syringing the plants occasionally in summer with a decoction of quassia, in which a little softsoap is dissolved. The bitter is unpalatable to the aphides, and the soap hinders them from obtaining a firm foothold. We are informed that this destructive species of aphid was introduced with Chrysanthemums from America, and it has given much trouble to some growers of the plants in this country.

Lichens on Apple Trees (E. J. F.).—It is best to remove the cause—namely, a too wet soil and want of vigour in the trees. The remedy for the first is efficient draining of the ground, putting in pipe drains 18 feet apart and 3 to 4 feet deep. The drains should, of course, have proper falls and outlets. If the trees are on grass—i.e., in orchard—we should apply in winter a good dressing of the *débris* of the rubbish-heap, which can be thrown into a heap now along with one part of quicklime to six of the rubbish. The woody portion of the rubbish should be picked out, and, when sufficiently dry, charred, and added to the compost, which should be turned after it has laid six weeks, and in six more it may be applied to the ground as a surface dressing at the rate of thirty-six cartloads per acre. If the trees are in cultivated ground they should have the surface soil scraped from about them as far as a majority of the roots extend, but without injuring them, giving a top-dressing of the material above named, to which has been added a fourth of good turfy loam if it can be obtained, and mulch with a couple of inches thickness of fresh manure, covering this lightly with the soil scraped off, and the remainder may be spread over the surrounding ground. The trees should have the stems scraped as well as the thick branches, so as to remove the lichen, and then washed with a brine formed of salt, which should be sufficiently strong to float an egg. The parts that cannot be reached with a brush may be syringed with the brine, but it must be only at midwinter, when the trees are dormant, and when the weather is mild and dry. If the trees are bushes or pyramids they may be dusted whilst wet or after a shower with quicklime, and if done efficiently it will destroy the lichen. The lime should be applied when the trees are dormant.

Large Mushrooms (W. B.).—The specimen sent is one of the *Boleti*, possibly *B. edulis*, but we are not certain, as it was imperfect; and, at any rate, it is not poisonous provided it is cooked in a fresh state, stale examples being more or less injurious. The following is the description of *Boletus edulis*, extracted from "The Eatable Funguses of Great Britain":—"A handsome Fungus, often attaining a considerable size, much exceeding that of any other of the genus. The pileus is brown, convex at first, but becoming plane in maturity, and sprinkled with fine powder. The flesh is pure white. Neither it nor any other part of the plant turns blue when wounded, as is the case with the deleterious species. The tubes vary in colour at different stages of maturity: at first they are white, then lemon colour, then of a full dull yellow; they turn olive colour when bruised. The stem is thick and solid, white in youth, but turning brownish in maturity; it is covered towards the summit with a fine network of pinkish veins. The spores are olive green, and after they are shed the Sap-ball sinks quietly to decay. This species is pretty frequently present in woods, especially under Oak trees in the south of England. It appears during the summer months or early in autumn, and a succession of plants follow one another till checked by the frosts. To recommend the Edible Sap-ball as merely wholesome is to inflict upon it the injury of half praise. Ancient and modern gastronomists unite in pronouncing it "excellent" and "delicious." It was well appreciated by the ancient Romans, though the *Amanita Cesarea* was accounted more fashionable by them, and Pliny describes it as an article of diet. It is sold under the name of "Porcins" during the winter in every market of modern Italy. In Lorraine it is called the "Polish Mushroom," because the use of it was there introduced by the Poles. In Russia it is preserved by drying until the annual fasts, when, simply boiled, it becomes an article of welcome variety. There are but few edible species in the *Boletus* group, and, though M. Vittadini asserts that all are wholesome if dried first and then cooked by stewing, we would rather not venture to eat them. The *Lurid Boletus* has an especially evil look. The Germans record their suspicions regarding it by the popular name they have bestowed upon it—"Satan's pilz;" and we should object to eat it were it ever so dry or ever so well stewed. In seeking, therefore, to obtain the luxury of a dish of the Edible *Boletus*, we must be on the watch for the points of distinction between the wholesome and deleterious species. The latter turn blue when wounded. None of the edible species turn blue. The delicious Edible *Boletus* is distinguishable from the undesirable Chestnut one (*B. castaneus*) by the stem; that of the latter being covered with cottony fibre, and that of the former with smooth netted veins. The specimens should be gathered in the immature stage, when the tubes are lemon colour. To cook the Edible *Boletus* you must first scoop out the tubes with a silver spoon or knife; cut them in pieces, and lay them in a dish, with butter, pepper, and salt; cover the dish close, and bake for one hour. Persoon gives a more elaborate receipt:—"They may be cooked with white sauce, with or without chicken, in fricassee broiled or baked with butter, salad oil, pepper, salt, chopped herbs and bread crumbs: to which some add ham or a mince of anchovy. They make excellent fritters. Some roast them with onions (basting with butter); but as these take longer to cook than the *Boletus*, this must not be put down till the onions have begun to soften." Paulet gives a receipt for *Boletus* soup made in Hungary:—"Having dried some *Boletus* in an oven, soak them in tepid water, thickening with toasted bread till the whole be of the consistence of a puree; then rub through a sieve, throw in some stewed *Boletus*, boil together, and serve with the usual condiments." Caution.—The *Boletus* which has the worst character for its poisonous qualities is the *B. luridus*. In this species the pileus is brown, and generally covered with white or grey bloom, which disappears in age, and leaves the pileus smooth or sticky. The stem is stout, inclining to bulbous at the base, of a dull pale vermilion colour, dotted or lined with a darker shade. The tubes are also dull vermilion at the mouth, but if the Fungus be cut in half the upper part of the tube is seen to be of a yellow colour. It changes to blue when bruised. *B. satanas* is a very nearly

allied species, the pileus becoming pale after maturity, and the red stem being without markings. Both are handsome and accounted poisonous."

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*High Broom*).—No one here can read your name now you have sent it. We named all the fruits received with letters accompanying them, on and up to September 23rd in our last issue, except some from "A. C.," and the names of these are as follows: (A. C.).—PEARS.—1, probably Beurré Bosc; 2, too unripe; 3, Fondante d'Antonne. APPLES.—1, Cobham; 2, Irish Peach; 3, Ribston Pippin. (T. W. G.).—1, Flanders Pippin; 2, Cornish Gilliflower; 3, Blenheim Pippin; 4, Autumn Pearmain; 5, Hoary Morning, small specimens; 6, Ord's Apple. (J. F. W.).—Williams' Bon Chrétien. (F. R.).—Swan's Egg. (H. W.).—The Grape in Gros Maroc; the Apple we do not know. (*Grower*).—Plums: 1, Tardive de Chalons; 2, Pond's Seedling; 3, Morocco. The Pear is Louise Bonne de Jersey. (A Subscriber).—1, Not known; 2, Vicar of Winkfield; 3, Louise Bonne de Jersey; 4, Uvedale's St. Germain; 5, Jersey Gratioli; 6, Catillac. (*Bromborough*).—Beurré Hardy. (T. E. F.).—We are sorry we cannot identify either of the Apples. It is most difficult to determine the Apples of Yorkshire, of which there are so many local varieties. (C.).—Pears: 1, not known; 2, Duchesse d'Angoulême; 3, Beurré Capiaumont. Apples: 1, Winter Strawberry; 2, Adams' Pearmain.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (J. C., *Wavertree*).—1, *Selaginella Kraussiana* Browni; 2, *Selaginella apus*; 3, *Plumbago Larpetae*; 4, *Adiantum cuneatum*; 5, *Astilbe rivularis*; 6, *Clematis Jackmanni*. (P. J.).—1, *Crataegus coccinea*; 2, *Carya porcina*; 3, We received no specimen with this number; 4, *Bryonia dioica*; 5, *Polygonum aviculare*; 6, The specimen was an unsatisfactory one, but it resembles *Thunia occidentalis*. (D. A.).—The Orchid is *Dendrobium Dalhousianum*, and is quite distinct from *D. formosum giganteum*, which has large white flowers. (J. H.).—1, *Solidago virgaurea*; 2, *Lychnis diurna flore-pleno*; 3, *Euphorbia cyparissias*; 4, *Pyrethrum uliginosum*; 5, *Veronica Andersoni* variegata.

COVENT GARDEN MARKET.—SEPTEMBER 30TH.

OUR market still well supplied, prices inclined to improve.

SOME LESSONS OF THE PAST.

HARVEST is over. With the exception of roots the crops are all cleared from the land, and the results of another year's work are before us. Each year brings its peculiar lesson, and now that Michaelmas is here and the farmers' year is ended and begun again, we may well give some thought to our work and its results during the past twelve months. What is our object in doing this? It is to weigh well the cause of success or failure, to see if our plans made last Michaelmas

bear the test of results now; to strive to pick a few golden grains out of the sands of time to add to our treasury of knowledge—knowledge that may be well termed golden, for it has been purchased at the cost of another year taken from the brief span of our lives.

The weather continued fine till late in autumn last year; did we turn the rare opportunity for cleaning the land to full account? Some did, but many a farmer did not, as we know to our cost, for we have recently had to let two farms at reduced rents owing in some degree to the foul condition of the land. Low prices for farm produce press heavily upon us now, but do not let us make bad worse by slovenly farming. Full advantage was taken of the fine autumn to sow green crops for early feeding in spring as well as winter corn; how invaluable were the earliest of those crops in the late spring of this year! Yet how many farmers had no such crops to fall back upon, and what a serious matter the late spring was for them, for the hay crop of 1884 was a light one upon many a farm, especially where pastures were inferior. We recently had an application from a tenant for a reduction of rent because he found hard times press so heavily upon him. Well, his plea was met by a reasonable concession, but we could not accord him unqualified sympathy, for we knew he was a bungler who either through ignorance or carelessness failed to turn his farm to best account, and who was wont to complain of hard times, yet had no thought that it was possible for him to do more for himself than he used to do when Wheat was 50s. or 60s. a quarter, and mutton could be sold by the carcass at 1s. a pound to the butchers. Last April, when we called at his farm, his hayricks were almost finished, his store of roots running low, his cows turned out on bare pasture, his sheep upon the last field of Turnips, and there was no Thousand-headed Kale, Cattle Cabbages, or Rye upon the farm. We feel bound to add that in our opinion such poor practice and practitioners must soon become numbered with the things of the past.

In the application of artificial manure to winter corn the plan we have so frequently recommended of giving a half dressing in the autumn at the time of sowing, and the other half dressing in February, was followed with complete success both for Wheat and winter Oats. The straw was stout and tall, but it was not so at the expense of grain, for it bore fine ears of well-developed corn. When the formula for these dressings was first published exception was taken to it on the score that the quantity of nitrate of soda and nitrate of potash given in it would induce a rampant straw growth with a deficiency of corn; this we are glad to say proved decidedly erroneous, and results justify our strong recommendation of the dressings. By sowing artificial manure upon the grass in February we had a full crop of hay last year notwithstanding the drought, and similar practice this year gave results that were really wonderful, for our hay crop was fully double the bulk of that of last year, and the quality of the hay is excellent. No doubt late spring rain did much for the grass, and the extraordinary crop of hay was a result of favourable weather and judicious culture, nature and art in perfect accord. If only we could always insure such perfect conditions, then should we indeed be able to grapple with our difficulties. At any rate we will keep on trying, doing all we can to improve our culture, avoiding extravagant expenditure, but doing all that is necessary to render and keep the soil fertile. This last point is worthy close attention. Are we to retain our cattle yards, to go on breeding and rearing animals solely for the manufacture of farmyard manure? or is it possible to avoid this slow and costly process by the use of artificial manures? After some five years' careful comparison of them we are bound to say that the manure carts must go, and so, too, must the special mixtures of the manure dealers. We must procure pure artificial manure from a reliable source, mix them ourselves upon the farm, and give close supervision to the time and manner of using them. To do this in the right way a farmer must know all about the soil and its requirements and it is precisely the

man who will set himself to acquire the knowledge that will enable him to master this important step in farming, who will be most likely to overcome other difficulties arising from low prices and foreign competition.

Regarding the soil simply as a medium for conveying food to plants, and not as an animal that will tire and require rest, we have only to take care that it always contains an ample store of sound and wholesome food, known under the comprehensive designation of fertility to insure full crops provided other points of culture receive equal attention. We must know, therefore, what elements of fertility each crop extracts from the soil, and in what proportion, too, if we are to apply manure correctly and economically. But we must not depend entirely upon purchased manures, rather striving to avoid all expenditure of money upon them that we can by growing our own manure in the form of green crops.

(To be continued.)

WORK ON THE HOME FARM.

Trifolium seed under the genial influence of moist warm soil was so quick in germination that the plant is up and growing freely. Rye and winter Oats are sown, ploughing for Wheat goes briskly on, but the rain has much hindered the cleaning of foul land. No opportunity of doing this should be missed, for land cleaned in autumn is at our disposal for early cropping in spring. Left foul till spring it cannot usually be got clean and ready for cropping till May or June. Land drains should be put in hand at once, for the soil is softened sufficiently by rain to render the work easy, and we strongly commend the plan of doing a certain quantity of draining yearly upon all wet land, for wet soil is a serious hindrance to work as well as to the healthy growth of any crop, no matter how heavily it may be manured. Let this be clearly understood, that undrained soil is fettered just as though a foul demon held it in its clutch. Cold, sluggish, and inert plants may live, but they cannot grow freely in it, for not only is the soil cold, but the temperature of the atmosphere close to the surface is lowered by excessive evaporation. Set free the water by drains and how great is the change! Superfluous rain water passes quickly through it, air enters freely, for its pores are open, and it can now receive and absorb the fertilising gases from air and water and become charged with nutriment suitable for plant food. We have been threshing some corn for food, seed, and market. Peas and Barley of good quality bring a remunerative price now. Barley secured in good time is a bright, heavy sample, but late Barley is much discoloured and must be used for home consumption and for grinding. On some exposed land the crops suffered severely from high winds, a considerable proportion of the ears being beaten off, so that we are as yet unable to determine what is our average crop per acre. We have grown Barley this season upon five farms in light, medium, and heavy soil, and it will be interesting and useful to note and compare results later on. Except for home consumption no Wheat will be threshed at present, for we hope still that it will answer to withhold it from market for a few months. The most reliable statement that we have of the Wheat crop of the world shows a probable deficiency of 9,000,000 quarters, and this quantity ought to exercise a healthy influence upon the markets of this country eventually. The nights grow cold and store cattle must be taken in the yards and let run out by day. To expose cattle now to cold wind, early frost, and heavy rain, is to risk a heavy loss, for they cannot sustain exposure to inclement weather with impunity.

REMARKS.

20th.—Fine bright day.
21st.—Rain early; afterwards fine and bright.
22nd.—Fog early; afterwards fine bright to warm.
23rd.—Cloudy morning; wet afternoon and evening.
24th.—Fine and bright.
25th.—Generally fine but cloudy, with a slight shower about noon.
26th.—Fine, bright and cold.

Cooler than the average, and about 5° below the previous week, but drier and brighter.—G. J. SYMONS.

YUCCAS, OR PALM LILIES.

THERE are few plants which in bold characteristic beauty can equal these in garden scenery. They are not, however, so frequently seen in gardens of a picturesque character as their merits entitle them to be, and they seem to be forgotten by planters and landscape gardeners. What is more stately or effective when judiciously planted in bold masses? or what is more productive of tropical effect than these Yuccas? Their value as flowering plants also should not be overlooked, for their giant panicles of creamy white bell-shaped flowers contrast most favourably with the various low-lying shrubs and Coniferous plants, which, unfortunately, are only too seldom found bearing them company. One of the finest groups known to me is that in the garden of Bitton Vicarage, which is very handsome, not three or four in formal assemblage. This group is in itself a great feature in Canon Ellacombe's garden, and one which might advantageously be imitated in gardens generally, where diversity of foliage would lend additional charms to the landscape. There are many places in the garden suited to display these to advantage—such, for instance, as on the margins of large shrubberies, in prominent positions on the lawn, or on the summit of a mound, where the pendulous-leaved species may, perhaps, be most useful. The large rock garden also affords positions in which such plants would be perfectly at home, and in the construction of a spacious fissure might be left for the purpose. If memory serves me there are some examples of this style of planting on the large rockery of Dr. Latimer Clark of Sydenham Hill, whose garden, it may be remarked, illustrates in a variety of ways the value of judicious selection and planting. Then there are one or two species of smaller dimensions, which are by no means out of place in the small rockery amongst Sedums, Sempervivums, or similar plants.

The genus itself is noted for the somewhat slow growth of all its members, and in many cases it takes years, depending much, however, on the soil and situation, before they make handsome specimens. When once planted they should remain undisturbed, for they are somewhat impatient of much interference at the root. They are increased by seeds or by offsets, which in some species are found rather numerous about the bases of the plants. These should be stripped off with a heel attached, and if examined previously a root or two may be found attached in some cases. They are also increased by "toes," which are the long white fleshy roots which protrude from the main body, that if left alone would ultimately produce suckers. When moving the plants these roots may be detached and placed in boxes of earth in slight warmth, where they will soon commence growth; or in the case of valuable and rare species or varieties they may be cut into several pieces after the manner of the stems of *Dracenas*, and if placed in gentle bottom heat the majority will break into growth.

Some of the Yuccas are among the oldest inhabitants of our gardens, and in the case of the well-known *Yucca gloriosa*

it is now verging on three centuries since its introduction from North America, and notwithstanding this great lapse of time it still remains one of the noblest, adapted either for grouping or isolated positions. Its general aspect is somewhat rigid. It attains large proportions, and is rendered conspicuous by its massive bearing, the flower stems not unfrequently attaining a height of 6 feet or more. The panicles are large, bearing a great number of white flowers. A very distinct variety known as *glaucescens* is equally ornamental in all respects. The leaves are broadly concave, and assume a pleasing glaucous hue. The flower stems are not so tall as in the type. Another variety with narrow leaves is *angustifolia*.

The next useful species for outdoor decoration is *Y. recurva*, a very graceful and exceedingly handsome plant. This grows about 4 feet high, the leaves of which are well recurved. Small plants of this are very serviceable for large vases in the terrace garden or for various similar purposes of decoration. The flowers are arranged in panicles, and are creamy white slightly tinged with red on the outside. It is certainly one of the best and most ornamental of the group. *Y. flaccida* is very distinct and noteworthy, as it forms clumps. It is not unusual to have three or four flower stems annually from one clump, the height being about 2 feet.

Yucca filamentosa and its forms afford a very pleasing variety. The typical plant is an old inhabitant of gardens, and comes from Virginia, height about 3 feet, with creamy flowers. *Y. filamentosa antwerpensis* is a distinct form of the preceding, with long narrow erect glaucous leaves, having only few filaments on the margin, the flowers sulphur tinted with green. The variegated-leaved form of this plant has no equal among hardy plants in the open ground, being perfectly hardy, and when placed among greenhouse plants fills a position of equal prominence. A large bed of this has stood unprotected for several years in the Chilwell Nurseries. It makes an excellent bed, and where sufficient exists it might with advantage be thus employed, filling the spaces with spring-flowering bulbs, such as *Scillas*, *Chionodoxa*, *Dog's-tooth Violets*, *Anemones*, and a group or two of *Liliums*. This *Yucca* succeeds in equal parts of peat and turfy loam, a mixture which will well suit the plants I have named; and such a bed when well established would no doubt be productive of good effect. It may be best to employ coloured *Liliums*. *Colchicums*, too, among autumn bulbs would be very useful in this way.

A noble plant is *Y. Treculeana*, which is of Mexican origin, and allied to *Y. canaliculata*. Its general habit is more erect, with narrower leaves. The flower stem attains a height of 4 feet, and is much branched. These are furnished with long varnished yellow and white flowers with reddish bracts. This is still an uncommon plant in gardens, and is one of the most desirable of this genus. *Y. canaliculata* is still a very fine species, and one whose value must not be underrated; indeed, it is sometimes regarded as synonymous with *Y. Treculeana*, though quite distinct from it. The leaves are long, broad, much concave, and of a dark green margined with red. It is very ornamental. Very distinct and rare is the small-growing *Y. Whipplei*, suited for the rock garden in a good sunny position. The leaves are rather narrow, somewhat tapering, and of a glaucous hue. Not having seen any very large examples of this I am not sure of the height which it usually attains. Nearly related to it is *Y. stricta* from Carolina, which seldom exceeds a foot in height. It also is adapted for association with the one previously named.

In *Y. aloifolia variegata* we have one of the most conspicuous of greenhouse foliage plants, and one equally well suited for sub-tropical arrangements out of doors in summer. All the year round it is attractive. Distinct from all existing forms is its thick Aloe-like leaves, which are somewhat fleshy. Being comparatively hardy it does not require much artificial heat—indeed, it is even more hardy than the type in this

respect. Its thick rigid leaves beautifully variegated, generally white or cream-coloured, though not unfrequently it assumes a bronzy red hue, which renders it unique. Another remarkable species is *Yucca baccata*, the leaves of which are short, stiff, and erect, bordered with broad filaments, and not narrow and wavy as in some species; flowers Tulip-shaped and borne in panicles. There are still many more equally distinct, and in their way equally good, such as *longifolia*, *De Smetiana*, *filifera*, *stenophylla*, *Ghiesbreghtiana*, *albo-spica*, and others. Those noted above, however, will be found most serviceable of this picturesque group.—J. H. E.

INTERNATIONAL POTATO EXHIBITION.

TRIAL CULTURE OF SEEDLING POTATOES, 1885.

By generous permission of the Royal Horticultural Society the seedling Potatoes entered for International Exhibition have, as in former years, been grown at Chiswick under the superintendence of a sub-committee. Mr. A. F. Barron has carried out the views of this sub-committee to their complete satisfaction, and they have made a report which will serve as the basis of action for the Judges at the Exhibition.

The seedlings sent for trial numbered forty-two. They were planted in good time on a well-prepared plot of ground, fully exposed as regards light and air, but having the advantage of shelter sufficient to ward off light spring frosts. They suffered no check from frost, and throughout the season there has not been seen upon the shaws the slightest sign of disease. But the long-continued drought with a frequent low night temperature delayed growth, the early liftings being in many cases insufficiently matured for a sufficient comparison of merits. The later liftings were for the most part satisfactory—rain had improved the crop without causing injurious second growth, but a few sorts were noted as so far promising as to be worth special attention next year.

From the forty-two sorts in the trial four were selected for the highest award in the garden—namely, three marks for heavy cropping and three marks for high table quality. The names of these are:—

Faith (Fenn).—Top growth neat; tubers white, round, neat, uniform, ripening early. One of the best in this trial. Crop three marks, table three marks.

New Fluke (Ironside).—A white kidney in the style of the old Fluke, but with a finer skin and a bolder form, the tubers being mostly of exhibition standard. Crop heavy, and the quality fine. Crop three marks, table three marks.

General Gordon (Fidler).—A white round in the way of Schoolmaster. Top growth strong, tubers handsome. Crop three marks, table three marks.

The Colonel (Johnson).—A capital white-skinned variety in the style of the old Fluke, rather late, but in every way first-rate. Crop three marks, table three marks.

The following were found to be productive and worthy of commendation for the present, but the awards made were not sufficiently high to bring them within range of certificates in the present season:—

Salisbury (Ironside), General Gordon (Fletcher), Charity (Fenn), Reading Giant (Fidler), a great cropper; Bountiful (Fidler); Farmer's Pride (Hill), Emblem (Ross), Snow Queen (Fidler); White Beauty (Ironside), extra heavy crop; King of Russets (Lye), a heavy cropper of good quality in the way of Adirondack; Burton Hall Favourite (Johnson); May Queen (Dean), likely to be especially useful for early produce.

GRAPE "JOHN DOWNIE."

ON reading the report of the Fruit Committee of the Royal Horticultural Society upon the above Grape (page 293), the question that occurred to my mind is, Can there be more than one variety of John Downie in the market?

I am desirous of asking this question, because a gentleman from the north called here the other day, and he assures me that there are two distinct forms of "John Downie" growing at Dalkeith Park. More, when my friend was there it so happened that the raiser of "John Downie" was at Dalkeith also, and had come purposely to see it as grown by Mr. Dunn. The remarkable thing is, that after being shown both Vines and having closely scrutinised the Grapes he expressed his inability to say which was the Simon Pure. Perhaps Mr. Dunn will say if I am correctly informed in this matter.

When "John Downie" was sent out the gentleman in whose honour it was named sent me a Vine with a request that I would give it a trial in a late vinery. This sapling was duly inarched on

to a Lady Downe's Seedling, and at the present time carries four good-sized bunches. In the same house is growing Alnwick Seedling got direct from Mr. P. Bell of Alnwick. On comparing the two together, fruit, leaves, and wood, I can come to no other conclusion than that they are not distinct varieties.

While on this subject I would also like to ask if any Grape growers have ever noticed the similarity that exists between Alnwick Seedling and Trentham Black—the peculiar marbling in the bark when the young shoots are running out, and also the red blotching on the leaves when dying off are very similar. I am of opinion that if these two sorts and "John Downie" were grown side by side they would be found much akin if not identical.

For your inspection I beg herewith to send you samples of all three. Your opinion upon them will be valued by more than—J. MCINDOE.

P.S.—I ought to add that Trentham Black is taken from a Vine started in January, and was ripe in July; the other two are from Vines started in March. I have grown the Trentham Black for nearly twenty years.

[We cannot see any difference between the bunches and foliage of Alnwick Seedling and those of John Downie which have been sent us by Mr. McIndoe, and they both confirm the judgment of the Fruit Committee that the two are identical. We cannot form so decided an opinion of Trentham Black, the berries of which being highly ripened and shrivelled had lost their normal form. The true Trentham Black which we had from Mr. Fleming when he was at Trentham was a distinct Grape from Alnwick Seedling, the bunch being longer and more tapering and very much earlier; in fact it came in about the same time or soon after Black Hamburg, and about the same time as Black Prince. We should like to be informed where and by whom the Grape John Downie was raised.]

HINTS ON PREPARING FOR WINTER.

THE shortening days and cold nights remind us that before October is out preparations for winter must be completed. There are requirements in all departments which should have attention, and it is much better to be a little too early than too late in having half-tender plants under cover, storing crops which are liable to be injured by frost, and providing protection. When the season gets advanced the weather cannot be trusted, and a wet evening may lead to a sharp frosty morning. Greenhouse and conservatory plants of a half-tender character which may have been placed in the open air for the summer will be amongst the first to suffer, and they should be moved in without delay. Where there is no danger from frost the wind must be considered, as the gales we experience now will cut the foliage and do more harm than a few degrees of frost. A plant which is much blown about in the autumn will never prove satisfactory in winter. Place Cinerarias and Primulas in a frame or house where fire heat can be applied, and Orange trees in the greenhouse. The pots or boxes in which the plants are growing should be washed outside before they are placed in their winter quarters. Plants which have been exposed to the autumn rains will not have many insects, but where any do exist sponge or syringe them off.

All greenhouse plants which have been put out in borders during the summer may be lifted and potted at once. Pot the bulbs desired to flower from the end of November until March. Stake Chrysanthemums firmly and neatly, and take them into an unheated house. Where the plants are trained the final tying must be done. If abundance of flowers are wanted do not thin off any of the buds. Where specimen blooms are desired only allow one bud to remain on the top of each shoot, but we prefer the clusters of flowers in winter. Autumn-rooted cuttings of Pelargoniums can be put into frames. Heaths, which are always benefited by a sojourn in the open air in autumn, should be left out no longer.

A general cleaning of plant houses must take place. Weakly plants, which may dwindle on all winter and die in spring, had better be thrown away at once. We have many old Pelargonium plants which have been blooming profusely since May, but they are almost over now. We also have spring-rooted cuttings of all of them just coming into flower, so instead of keeping the old ones for the sake of the few flowers we might obtain from them we shall throw them away and give up the space to the young ones. Tuberous Begonias, Gloxinias, and Caladiums need not be kept in the best quarters now. They must not, however, be placed in a cold place, as this would cause them to decay. A warm corner will suit them, and they may be stood close together, as plenty of room can be given to the plants which are developing. As soon as the leaves have decayed shake out the plants and store them in leaf soil or sand in boxes or casks, and keep them in a dry place during the winter. Clear off all dead leaves from plants at this time. Cleanliness of the foliage and sweetness of the atmosphere are important

aids to the successful culture of all plants in winter. Shading is generally very beneficial in summer, but it is injurious in late autumn and winter. Remove every particle of it from the glass now.

The weather is not very suitable for repairing and painting in October, but leakages are productive of much evil and must be stopped. Fireplaces, pipes, and boilers must be in the best of working order. Flues may not have been used since last spring. They are seldom cleaned when done with, and it is not until a frosty night comes and someone goes to light a fire that it is discovered that the smoke channel is full of soot and leaking. The flue ought to be cleaned out from end to end before frost comes, a fire put on, and the joints tested, any damage repaired, and the whole dried before it is really wanted.

Few plants require so much water at the root or in the atmosphere in winter as during the longer days, and the gradual withholding of it should begin at once. We find our Pine Apple plants in houses rather deficient of heat keep very much fresher on the dry side than when too moist, and often our finest successional plants do not receive any water from a can or syringe from October until February. Many are astonished that our Orange trees, &c., keep so green in an unheated house during the winter, but we attribute this to careful watering. Prepare winter protectors. If the mats are worn buy new ones, but do not use them just as they come to hand, but tie the ends neatly, and they will last as long again. If straw is scarce save the best of it which is thrown out from the stable, dry it, and store it away for use. Wild Fern or bracken is very useful. Wherever it can be conveniently had cut it largely and stack it. It may be used for throwing over glass lights in the time of severe frost. It ought to be cut before it begins to wither, as when too far advanced much of it crumbles away, and nothing but the stems remain.

Store herbs and roots in quantity. Parsley is as good for flavouring in a dried state as when green, and as much of it dies off in cold weather gather and dry it largely. Onions should be dried and cleaned in a cool airy shed, and then stored in a dry room. Carrots and Beetroot may both be drawn, put into an open shed for a few days to dry, then store under ashes or sand in a cool shed or cellar. If Turnips are not likely to remain good much longer store them in a heap under cover. The Swedish and the yellow Turnips will bear some frost, but the white and purple sorts may become pulpy if left out. Parsnips are very hardy, and need only be stored to last over a period of severe frost. Clear away all dead leaves from winter greens, such as Cauliflower, Broccoli, Brussels Sprouts, &c. Some may think that dead leaves will afford protection, but they more often cause decay, and are unhealthy. Fruit trees do not need any special preparation for winter. Well-ripened wood will enable them to pass through the most severe weather without injury. Keep Vines, especially those on which fruit is hanging, free from decaying leaves and berries. Atmospheric moisture must be avoided and frost excluded.—A KITCHEN GARDENER.

THE PRIMULA.

(Continued from page 270.)

P. AURICULATA, Lam.—Although an extremely free-growing and profuse-flowering species, this is unfortunately rarely met with in gardens; and where we do find the name it is generally represented by *P. luteola*, a plant entirely different in all its characters. *P. auriculata* is nearly allied to *P. farinosa*, and this may account in a measure for its being sometimes called *P. megellanica*, Duby, which is a synonym of *P. farinosa*. The present plant (fig. 49) is, however, quite free from powder, the under side of the leaves being the same as the upper, quite green. They are as long again as *P. farinosa*, broader, and more erect. It grows from a few inches to a foot in height, with a clean stout scape, carrying a large head of closely packed flowers, varying from bright rose to rose and lilac-tinted, as large as a sixpence; leaves slightly denticulate, broad lance-shaped, bright shiny green, and with a prominent whitish midrib showing its whole length. It requires a shady cool place, on the rocky north-western aspect preferred, where it flowers freely and proves perfectly hardy. A variety called *rubra* has been lately introduced by Max Leichtlin of Baden-Baden, which promises to be a great acquisition. They are readily increased by the offsets or by seed. Native of Caucasian Alps, Olympia, Bithynia, &c. Syn., *P. longifolia*, Curt. Bot Mag.

P. BALBISII, Lehmann.—There seem to be two forms in cultivation, nearly allied to *P. Auricula*, and of which the type is considered a variety by many botanists. From experience in cultivating the plant I am inclined to keep up the separate specific name, as it differs widely from *P. Auricula* in a garden sense, and in a living state, whatever it may appear on comparison of dried specimens.

It will be found a more difficult plant to cultivate than *P. Auricula*, and great attention must be given to it during the winter, as it is liable to damp off when over-supplied with water. It is at the same time very impatient of drought. The compost I employ consists of three parts limestone, the other part being a mixture of loam and finely chopped sphagnum. It forms a thick fleshy root-stock, and care must be taken in wedging the stones round the collar not to injure it. Plenty of water is required during the growing season, but at other times must be kept rather dry. The plant seems to like a half-shady position, a west aspect being preferable. Although not often met with in the Alps, though not by any means rare, it is also found in Styria, and also between there and Indicien. Obrist says it grows in Indicien in the very deep regions, though not very plentifully. In habit it resembles *P. Auricula*. The leaves are, however, smaller and rounder on the cultivated plants. The glossy foliage is also a distinguishing feature, as well as their leaves being quite free from meal dust, which is one of the characters of the other. The flowers are large, shining golden yellow, with a hairy throat, and having no perfume. It is one of the rare plants of the Baldo, Villarsa, and the Alps of

Fig. 49.—*Primula auriculata*, Lam.

Southern Tyrol. It flowers May and June. Syn., *P. ciliata*, Morretti, non Shrank; *P. Auricula* var., Spr. *P. Balbisii* seems to be the one extreme, *P. Auricula* the other, with *P. similis*, Stein, and *P. Obristi*, Stein, intervening; crosses between the two, the one sub and the other super-Balbisii × *Auricula* of Stein in both cases.

P. BELLUNENSIS, Venzo.—One of the most recently introduced of the new Primulas from the neighbourhood of Belluno, a large town in the government of Venice. It is said to be a distinct species, which I doubt very much, as it has a near affinity to *P. Balbisii* and others, and more likely to be a cross between that and some other species, perhaps *P. Auricula* with super-Balbisii. It has flowered with us, however, and there cannot be a question about its value as a garden plant. When thoroughly established it is of freer growth than *P. Balbisii*, although having much of the habit of that plant. It differs in having longer and more oval-shaped leaves, showing the veins more prominently; the margins are deeply and evenly indented, rough, and densely ciliated, the winged petioles being about as long as the blade of the leaf. Flowers larger than a shilling, well formed, of a handsome golden yellow colour, and often with a slightly frosted throat. The compost used is the same as that recommended for *P. Balbisii*, with the addition of finely powdered mussel shells. Flowers during May. A fine rocky plant where it can be kept comparatively dry during winter.

P. BERNINÆ, *A. Kern*.—A hybrid between *P. hirsuta* × *viscosa*, *A. Kern*; *P. graveolenti* × *villosa*, *Obrist*. The plant as yet is small, and I have not been able to judge of its merits, not having seen flowers. According, however, to Mr. Stein, who saw it at Stendner's place at Munich, it is very fine. The leaves are much smaller than *P. viscosa*, slightly crenated edges, and covered with small glandular hairs, almost as broad at the base where it sheathes the stem as in the middle of the blade. We grow it in free sandy soil wedged between pieces of limestone. It is healthy and vigorous.

P. BIFLORA, *Huter*. (*P. Floerkeana* × *minima*, *A. Kern*).—A rare little gem among Primroses, surpassing our little *P. minima*, to which it is nearly allied. The leaves are, however, larger, more sheathing at the base, and more distinctly serrated. The flowers are large, in pairs on the short stem, deep rose, and extremely handsome, covering the whole plant, which is seldom more than an inch or so high. It inhabits about the same locality as *P. minima*, and flowers at the same time. It thrives well on limestone, with plenty of water during the growing season.

P. BOVEANA, *Décadise*.—The Abyssinian or Whorl-flowered Primrose belongs to a comparatively limited group, comprising among others, and perhaps best represented in gardens generally by the well-known *P. japonica*. It is nearly allied to *P. verticillata*, and according to Jaubert and Spach it is the plant that does duty for the latter-named Primrose, which, says Stein, is not in cultivation in gardens at all at the present time. The plant named *P. verticillata* var. *simensis* by Dr. Masters, which was introduced some years ago by Messrs. Veitch of Chelsea under the provisional name of *P. Courti*, I consider perfectly distinct from *P. Boveana*, although Stein has included it in his synonymy of that species, which is quite distinct from Richards' *P. Boveana* in the "*Abyss. Flora*," ii., 15, the latter being the same as the var. *simensis*, *Mast*. It has a much nearer affinity to *P. verticillata* than to *P. Boveana*, much larger flowers than the latter, and is altogether a more important garden plant.

Of *P. Boveana* the leaves are nearly erect, broad spatulate, with winged petioles. The margins are incised, and these again are minutely serrated. The stalks are erect, from 6 inches to a foot in height, carrying from three to five whorls, with about a dozen or more flowers in each, pale soft yellow and slightly perfumed. The most characteristic mark in this species is its sharply serrated calyx segments, which are about half the length of the corolla tube. The whole plant is powdery or mealy. Unless in extremely favoured localities this plant will not stand out of doors in this country during severe winters, and even in cold frames it often succumbs to the damp close atmosphere consequent on the lights being closed. It may be safely carried through mild winters outside, however, where it can be kept perfectly dry and free from stagnant moisture. It flowers from March until June, and may be readily increased from seed, which it ripens freely. Native of Mount Sinai, &c., and is reported to be found growing near the spot where Moses struck the rock for water. Syn., *P. verticillata*, *Bot. Mag.*, t. 2842. First introduced from Berlin about the year 1825.

P. CALYCINA, *Duby*.—This belongs to and may be taken as fairly typical of the section *Arthritica*, including *P. spectabilis* and others remarkable for their perfectly smooth glossy foliage. *P. calycina* (fig. 50) has been long known in gardens, where it is often confounded with *P. Wulfeniana*, a totally different plant, and from which it is easily distinguished, even without the aid of flowers, by its longer and very irregularly margined leaves. It grows readily enough on the rockery in almost any position, but unless in exposed situations is rather a shy flowerer, and I can only manage to flower it by giving it a good roasting during the summer months, meanwhile supplying water very sparingly. It seems to prefer being wedged between hard pieces of granite in a rich stiffish soil. It forms rosettes of long ovate-lanceolate leaves, of a half-weathered green colour, perfectly glabrous and shining, with a curiously wavy margin. Flowers large, of a beautiful clear lilac, generally three or four together on short stalks, at the base of which are long linear bracts. Calyx about an inch long, with narrow bluntish sepals. It is a native of the southern Alps, flowering with us in May and June. Syn., *P. glaucescens*, *Morett*; *P. lavigata*, *Duby*; *P. integrifolia*, *Wulf*.

P. CAPITATA, *Royle*.—The Round-headed Mealy Primrose is perhaps the finest of this section, and closely allied to the better known *P. denticulata*. It was first introduced to cultivation by Sir J. D. Hooker, who found it growing on gravelly banks at Lachen, Sikkim Himalaya, at an elevation of 10,000 feet above sea level. It has also been found common in the Hariab district in boggy and spongy meadow ground that is watered by springs at elevations of 8000 feet. Although a true perennial in its native habitats it can hardly be regarded as such in our gardens; for although a few will continue to flower the second, and even the third year, this is excep-

tional, and the majority of them die after having flowered once. It ripens seeds fairly well in good seasons, and a succession may be had in this way; but if the seedlings are raised in pots it is always safest to plant them out as soon as they are ready to handle, as their chance is greater than when kept in pots or boxes. Even when planted out I consider it lucky to have safely wintered half the plants in the south of England. A north exposure should be chosen, shady but open, and employ a mixture of rich loam and peat in about equal proportions. In dry weather they should be kept well watered; indeed they should never be allowed to get dry at the root, and as much care as possible must be taken to keep the water off the leaves. The seed may be sown as soon as ripe in the autumn, or kept until spring. The latter we think the safest, as the plants gain strength enough to carry them through the winter without showing flower until the second year, unless the situation be too hot.

P. capitata grows about a foot high, each plant bearing two or more scapes, and each carrying a large globular head of flowers not unlike a Sea Pink or an Allium. The flowers are sessile, closely packed together, deep purple, set off to the best advantage by the mealy dust that covers the whole plant. The leaves are radical,

Fig. 50.—*Primula calycina*, *Duby*.

about 6 inches long, oblong lanceolate, rugose, with sharply serrated margins. From seedlings two good varieties have been lately introduced under the names of *cœrulea* and *atroviolacea*, the latter being by far the best colour we have ever seen. Another called *grandiflora* seems to be a hybrid. It has distinct leaves, and improves on the type in the size of its flowers. They flower about June.

P. CARNIOLICA, *Jacq*.—About this very little seems to be known in gardens, although its merits are such as to entitle it to a first place amongst hardy alpinists. It also has the advantage of growing with remarkable freedom on the rockery, where it can get a dry bottom and plenty of sunshine. It will do well in an almost perpendicular position, with just sufficient soil to cover its roots. The large loose rosettes of leaves are very pretty during summer. They are about 2 inches long, ovate lanceolate, but again broadening where they clasp the stem, perfectly glabrous, and shining as if varnished on the upper surface; sub-repand, not cartilaginous at the edges. Flower stalk about 3 or 4 inches in height, carrying from three to eight flowers about an inch in diameter, pale or deep lilac, with a silvery white centre. Though thin-textured they last a considerable time in beauty, the contrast against the pale greenish foliage being very striking. It flowers May and June, and is a native of the Alps of Carinthia and Carniola. Syn., *P. integrifolia*, *Scop*; *P. Freyeri*, *Hladn*; *P. Jellenkiana*, *Frey*; *P. grandiflora*,

Bast. There are varieties named multiflora and multiceps, the latter being in cultivation.—D.

(To be continued.)

THOUGHTS ON CURRENT TOPICS.

To all readers and writers who have been good enough to make inquiries concerning me I make my bow, and step to the front once more. I am credited with having enjoyed a "long vacation," certainly a novelty to a gardener; rather let me say I interpreted the editorial note on page 135 (August 16th), that "sufficient had been said at present" on a subject then under discussion, as a hint that I should "take a rest," and I took one, and here let me say I am so averse to being obtrusive that if I had not been invited to do otherwise some "thoughts" would have been kept to myself that will now be made public for what they are worth.

THE subject of the cracking or splitting of Grapes was a very prominent topic when the editorial curb was put on. I do not say it was not prudent to "draw the rein," it probably was. When Galileo was compelled to make his historical recantation as to the movement of the earth, and was impelled to say it did not revolve round the sun, he did so to "save his neck," but in an undertone to his friends he committed his real convictions—"but it does." So in the case of the rupturing of certain Grapes, my belief remains the same, that the evil is mainly in the atmosphere—an excess of moisture, which passes through the skins, and not primarily at the roots. There, the die is cast, and my opponents can hang me—metaphorically—if they like, as the Grapes will split all the same if an opportunity is afforded them by too much moisture in the air of the house.

OF what shall I "think" next? It shall be on the subject suggested—gardeners' vacations. These are necessary in moderation, instructive, or ought to be, and profitable alike to master and man. It is one thing for a gardener to desire to indulge in gadding about from place to place without any particular matter of duty calling him from home, but quite another thing for a man to have no relaxation from absorbing and often laborious work from year's end to year's end. I am able to speak with authority on this matter, having had to work for five years without a holiday, and often during that time swinging the scythe at three o'clock in the morning, and watering plants at nine o'clock at night, or eighteen hours, and no pay for "overtime." That was in the "good old times;" but the work, though hard, was done cheerfully, as it ought to be, or let alone, and the term of incessant labour won confidence, when freedom followed. This certainly would not have been continued if the wage-payer found his garden degenerated or his interests suffered. He found just the reverse, and so far "improved" as to defray my expenses at least once a year to any part of the country where I could gain knowledge for investing in his property.

THERE are numbers of hardworking gardeners and faithful servants who have well earned a few days' holiday, and must still go plodding on because those whom they serve do not think—for it is nothing but want of thought in many cases—to afford them an opportunity of "gettin' away" for a little time for rest and instructive recreation. But let it be remembered that no man has a right to expect such encouragement until he has proved his worth by his zeal and ability.

AT no period of the year can gardens be left with more confidence that nothing will suffer than during the present month. Propagating is completed, plants are made safe for the winter, fruit is gathered. On the 21st the great Pear Congress opens at Chiswick, and the Editor has been good enough to suggest the occasion opportune for the acquirement of knowledge by gardeners on the most important of all hardy dessert fruits. Railway excursions are numerous, travelling cheap, and once in London the collections can be seen every day for sixpence, and then the great Inventions Exhibition, with the brilliant evening fête for a shilling, except on Wednesdays. Let me venture a word respectfully to all who have worthy gardeners in their service to encourage them, so far as can conveniently be done, to lay down the shovel and the hoe for a few days and share in that which will benefit them without anyone or anything being the worse, but on the contrary the probability, amounting almost to a certainty, that all will be the better in the end.

ONE of the most prominent topics under discussion in the Journal during the past month has been the judging of fruit. I think all must recognise the thought and labour that have been

devoted to this subject by Mr. W. Wilkinson in the preparation of the exhaustive paper that was read by him at Dundee and published in the issues of the 10th and 17th ult. When I read that production, for which a vote of thanks is due, I had an impression that it would evoke little or no discussion, because of its being too elaborate. Good the plan may be in determining the relative merits of competing dishes, but I suspect there is not one collection of fruit staged out of twenty where really competent judges would find such a system of judging necessary; and to adopt it through the classes would be so tedious that the work would not be completed in anything like the time at disposal.

I AM inclined to think that by far the greater number of mistakes that occur in awarding prizes are traceable to three primary causes—1, Indefiniteness in the conditions or description of classes in schedules. 2, Late staging and, consequently, want of time for close and careful examination of the products staged. 3, Inexperienced judges—that is, persons not having special knowledge of the exhibits in the classes to which they are appointed. Some men are selected because they have a "friend in camp;" others because they reside near and are regarded as cheap. Local judges, however honest they may be, are accused, often unjustly, of favouritism at local shows; and "cheap" judges are often ruinously dear in the end, for horticultural societies soon lose character and degenerate if exhibitors have not confidence in the adjudicators. "Judges should receive no pay for their work" says Mr. Williamson; in that case the best of them cannot be had, for men of wide repute are retained for months in advance—in some instances a year—and the alternative appears to be that instead of the "great unpaid" we should have the little unpaid, and it is doubtful if this would be a decided advantage. In this, as in other matters, I think the rule holds good that "the labourer is worthy of his hire."

IN more than half the classes at exhibitions judging by points is needless, and would be a positive waste of time; in very close competition it is essential, and in no other way can the merits of the products be ascertained with exactitude. Two or three men can quickly decide on a standard of merit, jot down the "points" accordingly, and make an addition sum on the back of a schedule. To enter their "remarks" on cards would waste precious time with no corresponding advantage, for if the observations were not published, of what use would they be? While if they were published they would form lengthy texts for ten times more wrangling and disputations than are prevalent now, and there is quite enough of "that sort of thing" to satisfy the most hypercritical, especially when, as a rule, the most noise is made by the most ignorant. Given, then, clear conditions, a reasonable amount of time, good men, and judging can presumably be accomplished with less ceremony than your able correspondent advocates, and well-founded causes of complaint will be reduced to a minimum. As it seems a pity the comprehensive paper alluded to should not have the honour of criticism, I have ventured to "set the ball a rolling."

RELATIVE to the controversy on awarding prizes for Grapes at exhibitions, the whole question turns on the purpose for which the objects are staged. In most cases this purpose is to make an imposing display that will attract the public and bring "gate money." This being so, as I think it is, late varieties of Grapes cannot be excluded from summer shows. If they were the exhibitions would be meagre in an important department, and not only would general visitors be dissatisfied, but even gardeners would be disappointed.

WELL-GROWN and coloured bunches of Alicante, Mrs. Pince, Gros Colman, Gros Maroc, Alnwick Seedling, and Gros Guillaume, at what are termed summer shows, or shows held before the month of October, though the quality of the fruit may not be developed excellence of culture is nevertheless displayed; the examples, consequently, are both interesting and instructive to numbers of gardeners who would not see them at any other time, and therefore deprived of recognising how far they are behind and what they have to strive for in the production of first-rate Grapes. For these reasons it is very questionable if it would be prudent to encourage no other "black" varieties than Black Hamburgh and Madresfield Court even in August. It is also questionable in my opinion if the second condition proposed that "all Grapes shown must be in season," were unreservedly applied that the effect of it would meet with anything like general approbation.

THOUGH I am thus far at issue with Mr. Iggulden and his supporters, I do not despair of bringing myself in harmony with

them. At any rate, I will suggest a compromise for their consideration. It is not practicable to give prizes for the best examples of different varieties of Grapes at all shows, and at most of them held in summer the usual classes for Black Hamburgs and "any other black variety" will have to suffice but where the finances permit it is very desirable to have a class for encouraging the better and more extended culture of Madresfield Court. Now, why is the Black Hamburg taken as the type of black summer Grapes? Obviously because it is "in season." Should not, then, other varieties that are associated with it and placed in competition in the orthodox classes be "in season" too? That, to my mind, seems both logical and reasonable, and I would have a note appended in the schedule that the prizes in these classes should be awarded for "appearance and quality." If the Alicante, Gros Colman, or any other in those respects excel let them have the prize, not otherwise. It is true there may be a clashing of virtues, for bunches of Alicante may excel in appearance, Madresfield Court in quality. What then? Let experienced cultivators and competent judges determine which they would prize the most if they had grown them, and which they would choose for a high-class dessert, and there would be so few mistakes that grumblers could be ignored.

Now to the Grapes not "in season." These should, indeed must, be included in the classes for four, six, or more varieties, and be in appearance fit for table, a note being inserted in the schedule that the prizes in these classes be awarded for "excellence of culture." Growers having these Grapes in presentable condition previous to October could then stage them, have the recognition they deserve, while the best possible displays of Grapes would be provided for inspection and instruction. This is one way out of an admitted difficulty; but the better way, as above suggested, would be to have classes both for the Black Hamburg and Madresfield Court, then another for "any other variety." At numbers of shows this could be done, and this fine summer Grape is deserving of encouragement. At present, quality is often swamped by size, according to the peculiar fancies of persons appointed as judges, and the absence of any instruction in schedules to guide them in awarding the prizes. For instance, a gardener staging Madresfield Court in a "variety class" would vote for Mr. Gguldén as a judge, but if exhibiting Alicante he would hold up his hand for "A Kitchen Gardener." Good prizes should be offered for late Grapes at winter and spring shows.

THE active gardener last mentioned and Mr. J. Muir appear to estimate the merits of what is grown on diametrically opposite principles. Because we are "accustomed to hear Stephanotis and Gardenias praised so much" and they are grown so extensively, Mr. Muir would discard those plants; or rather their popularity is not regarded by him as sufficient evidence of merit, and he is disposed to throw them away. "A Kitchen Gardener" reasons otherwise in respect of Alicante Grape, and submits that because it is so extensively grown as to be everybody's Grape it must of necessity be good, and he accordingly advocates its culture. In one case the "public instinct" is trusted for giving a sound verdict, in the other it is not. Which is right is more than can be said by—A THINKER.

PEARS AND GRAPES CRACKING.

So much has been said in the Journal on the cracking of fruit, that it has induced me to try and find out the cause of the evil. Having a fine crop of Van Mons Léon Leclerc Pear, and knowing how subject it is to crack, made me keep a close watch on the tree. Every Pear was sound on the 23rd of this month; the three following days we had heavy showers, and my fine Pears went wrong. Out of 4 stone gathered from the tree I could only pick 1 stone of sound fruit, all the rest being cracked. All the damage was done to the Pears in six days. I believe that if I had gathered these Pears before they were quite ready or before this rain, I should have kept them all sound. The question is, What caused them to crack? Was it caused by the overflow of the sap from the roots owing to the rains, or was it caused by the sun's rays coming in contact with the Pears before they got dry? My opinion is that these are the two causes of the Pears cracking. First the overflow of sap from the root, second the surface of the Pear being rough holds the wet, which softens the skin, and cracking ensues; but why should this Pear crack more than others?

It is the same with Grapes, only we have not the same excuse because we have vineries, and Grapes crack just when they begin to colour, we have to give some reason for it. This is not so with the Pear and other fruit which is grown outside, as

owners of gardens, as a rule, will pass the cracking of this as a natural cause, but not so with the Grapes. In one of my vineries I have Alicante, Black Hamburg, and Foster's Seedling. The latter is the only one that has ever shown any signs of cracking, and it is worse this year than previously. To prevent this going very far I put a gentle fire on with plenty of air night and day. I found this answered very well, so much so that a gentleman from one of our largest estates in West Norfolk said he never saw anything like them before, and by taking a drive round to several places myself I find that where Foster's Seedling is grown with other Grapes there is the one fault of cracking. Why should this Grape crack so much while the black Grapes give no signs of cracking? Is it because the skin is so fine that it cannot resist the flow of sap which appears to be supplied in extra quantity just when the fruit begins to ripen? or is it from letting the moisture settle on the berries through not ventilating early enough in the morning? If this is the case, which I believe it is, why should it not be the same with the Pear? It seems to me that the cracking arises from the same causes, only the gardener is held responsible for the Grapes, while the Pear is passed with little notice.—J.W., *The Elms*.

[The Grapes accompanying this communication were good, but much crushed by the Pears. The Pears were also fine fruit, but the cracks in them have not been caused by the sun shining on the fruit when wet, because the fissures are on the shaded side, just where the fruit thickens and where the moisture remains the longest. This is a delicate-skinned Pear. It appears that fire heat and a free circulation of air checked the cracking of the Grapes, and perhaps if the air had been dried sooner the evil would have been averted. There is the same difference in the texture of the skins of Grapes as in those of other kinds of fruits. We know a garden in which the soil is very sandy and dry, and Pears grown in it can only be prevented from cracking by copious applications of water and thick mulchings of manure to check evaporation and keep the roots moist. Without this assistance the fruit cracks so seriously as to spoil the crop. In this case, dry and poor soil appears to be cause of the evil; but we are not prepared to say that a great influx of sap caused by heavy rains is not a predisposing cause of Grapes cracking, though we apprehend more danger from a damp atmosphere at a critical time. Delicate-skinned Grapes on Vines in pots stood on hot-water pipes and the roots kept purposely dry have cracked seriously through the effects of atmospheric moisture and syringing.]

PROPOSED INTERNATIONAL HORTICULTURAL SHOW IN 1887.—A Meeting of the Council and Committees of the Royal Horticultural Society is summoned for October 13th with a view of ascertaining the possibility of holding an International Show in 1887.

— THE first meeting of the FLORAL COMMITTEE OF THE NATIONAL CHRYSANTHEMUM SOCIETY will be held at the Royal Aquarium, Westminster, in the Organ Gallery, on Wednesday, Oct. 14th, at 2.30 P.M. precisely, when new or rare Chrysanthemums or other subjects may be submitted. Certificates will be awarded according to merit. Exhibitors can obtain admission to these meetings by signing the attendance book at the staff entrance of the Royal Aquarium (next to the theatre). Exhibits should be staged not later than 2.15 P.M. Parcels (carriage paid) may be directed to Mr. William Holmes, Honorary Secretary, care of F. Cates, Esq., Royal Aquarium, Westminster. Exhibitors need not be members of the Society.

— MR. GEORGE BUNYARD of Maidstone has sent us specimens of TRIOMPHE DE VIENNE PEAR. They are large handsome fruits, some of them upwards of 4 inches in length. It is a deliciously flavoured Pear when caught at the right time, for it is one of those varieties that decay treacherously at the core while the surface is sound. We have also received specimens of that beautiful and valuable Apple Lady Sudeley.

— "W. D." writes:—"In reply to your correspondent's inquiry about MIGNONETTE MACHET in last week's Journal, I may say that it is a new variety which I received from Germany in the spring, and I regard

it as a very fine variety, of close-growing robust habit but short stature, with dense large spikes of flowers with brightly coloured stamens, and most fragrant. It is a great acquisition, and a thorough pot Mignonette. Out of doors the plants should be a few inches apart. This, Golden Queen, and Miles' Spiral, are three first-class Mignonettes."

— A FINE AUTUMN FLOWER BED.—One of the most effective October flower beds that has perhaps ever been seen is in beauty now in the grounds of Hampton Court Palace. It consists simply of a mass of Madame Desgrange Chrysanthemum banded with Aster Amellus bessarabicus. The bed is 25 yards long and 5 yards wide, and except the margin is a fleecy cloud, like a mass of creamy white flowers, so numerous as to appear as if piled in heaps. The plants are about 4 feet high, and the Aster edging about 18 inches high and broad. The thousands of deep lilac flowers of this, one of the most attractive of the Michaelmas Daisies, are displayed to the greatest advantage in contrast with the mass of white in the centre of the bed; in fact, one plant enhances the beauty of the other. Both these are hardy autumn-flowering plants of the first merit, and should be grown in quantity wherever an effective mass is desired at this season, and where flowers for cutting are in great request during the shooting season, after Dahlias have been cut by frost, and before the late October and November Chrysanthemums are plentiful. The bed in question has been in beauty for about a fortnight, and will last far into the present month. It is well worthy of inspection, and most persons who see it will determine to grow the two easily managed plants referred to, at least those will who have gardens and wish to have armfuls of flowers at this late period of the year.

— MR. A. HARDING writes from Orton:—"Two LARGE POTATOES were shown me by a cottager last week of the variety White Elephant that he dug in his garden. I never saw any so large. The two I put in the scales were over 6 lbs., the largest 3 lbs. 5 ozs. They looked like ninipins. He states that he has had several which weighed 2½ lbs. each."

— "SOLANUM" observes: "In my notice of the HAREFIELD GROVE COLLECTION OF TOMATOES last week, page 290, the Harefield Grove Red was described as highly corrugated. It should have been slightly corrugated."

— WE find we were in error when we stated, on page 272, that the young shoots of GRAND DUKE PLUM are downy. We have received specimens from Mr. Rivers, and find that they are smooth.

— IN Cheshire the gathering of BLACKBERRIES for Liverpool and Manchester markets now provides profitable occupation for the country people. Enormous quantities are being sent away. A mother and three children will earn 10s. and 12s. weekly Blackberry picking. Dealers from Manchester attend and give 1d. and 1½d. per lb.

— AN association for the PROTECTION OF WILD PLANTS has been started at Geneva. The object is to preserve alpine rarities from the extermination with which the annually increasing number of hotanists, collectors, and mountaineering tourists generally is said to manacle them. The projectors of the association announce that they are going to cultivate the flowers of the Alps in nurseries, and sell them at such low rates that it will not be worth anyone's while to dig up the wild plants.

— AT the recent meeting of the British Association in Aherdeen, Professor Gilbert, LL.D., F.R.S., contributed a NOTE ON THE CONDITIONS OF THE DEVELOPMENT AND OF THE ACTIVITY OF CHLOROPHYLL. This gave an account of some experiments made in conjunction with Dr. W. J. Russell, which show a close connection to exist between the formation of chlorophyll and the amount of nitrogen assimilated by plants; the amount of carbon assimilated is not, however, in proportion to the chlorophyll formed, unless a sufficiency of mineral substances required by the plants is available. In cases where both nitrogenous and mineral manures were applied a lower proportion of nitrogen assimilated and chlorophyll formed over a given area was observed, which is no doubt due to the greater assimilation of carbon and consequent greater formation of non-nitrogenous substances, although the amounts of nitrogen assimilated and chlorophyll formed were as great, if not greater.

— MR. JAS. CARRUTHERS, Gardener, Hillwood Gardens, Corstorphine sends us a few blooms of EARLY-FLOWERING CHRYSANTHEMUMS, and remarks "that he disbudded a few plants of Madame Desgrange to twenty flowers, and they average about 6 inches across. The yellow

sport is equally free. Mrs. Cullingford is, I think, one of the most useful Chrysanthemums grown." The blooms of Madame Desgrange were as fine as good examples of Elaine. La Vierge was also compact and pure white, Mrs. Cullingford being rather smaller but very handsome. The Golden Madame Desgrange was of charming colour and good substance. The bright rosy purple-tinted variety, Aureole, was represented by two beautiful blooms.

— MR JOHN C. MONTGOMERIE has recently been awarded a gold medal at the London International Exhibition for a collection of the excellent "TAM O' SHANTER" HONES we have previously noted in these columns.

— IT is said that a number of women and girls are now employed in France in GRAFTING FRENCH VINES ON AMERICAN STOCKS, and that a woman can graft as many as 300 Vines a day in the spring months. Some men are also engaged in the work, and these graft 600 or more in a day.

— THE Commissioners of Her Majesty's Works and Public Buildings intend to distribute this autumn, as usual, among the working classes and the poor inhabitants of London the SURPLUS BEDDING-OUT PLANTS in Battersea, Hyde, the Regent's and Victoria Parks, the Royal Gardens, Kew, and the pleasure gardens, Hampton Court. If the clergy, school committees, and others interested will make application to the superintendent of the park nearest to their respective parishes, or to the Director of the Royal Gardens, Kew, or to the Superintendent of Hampton Court Gardens, in the cases of persons residing in those neighbourhoods, they will receive early intimation of the number of plants that can be allotted to each applicant, and of the time and manner of their distribution.

— MR. J. MALLENDER sends his monthly SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for September, 1885:—Mean temperature of the month, 53.5°; maximum on the 15th, 73.0°; minimum on the 26th, 28.7°; maximum in the sun on the 5th, 124.3°; minimum on the grass 26th, 22.9°. Warmest day the 15th, mean temperature 62.4°; coldest day the 26th, mean temperature 40.8°. Mean temperature of the air at 9 A.M., 54.5°; mean temperature of the soil 1 foot deep, 54.9°. Nights below 32° in shade, one; on grass, four. Total duration of sunshine 150 hours, or 40 per cent. of possible duration. We had two sunless days. Total rainfall 1.77 inch. Maximum fall in twenty-four hours 0.22 inch. Rain fell on nineteen days. Wind mostly from S.W. to N.W. points; average velocity 10.2 miles per hour. Exceeded 400 miles on four days, fell short of 100 miles on three days. It has been a cold, bright, and showery month; temperature lower than seven out of the last nine years, while the minimum on the 26th is the lowest yet recorded. Rainfall less than the average, but a good many showery days.

— AT the recent Antwerp Exhibition Messrs. Rawlings Bros. were awarded, by acclamation, the GOLD MEDAL FOR FIFTY DAHLIAS, and the silver medal for twenty-five Dahlias. Mr. J. West, gardener to W. Keith, Esq., Brentwood, was also awarded the first prize for twenty-five Dahlias.

— MR. WILLIAM HUGHES, who is CELEBRATED AS A FRUIT PAINTER, has gathered together a collection of his works in the Burlington Gallery, Old Bond Street, to show the public that he is quite as much at home in landscapes and other subjects as in the department of art with which his name is more familiarly associated. The fruit pieces will, of course, come in for first notice. First, then, the visitor to the Burlington will look at the extraordinary mountain of fruit that is intended to represent Pomona's gifts to Italy. "So skilfully is each fruit form painted that the Grapes seem bursting out of the canvas, and the moisture of the open Melon seems to glisten in each ruptured fibre." Another large fruit piece is a tempting show of ripe Peaches, Pears, and other fruit heaped up on a marvellously painted rug. But perhaps the most perfect work of all is to be seen in the smaller work called "Nature's Jewels," in which a huge bunch of White Currants is depicted with such glossy transparency that they look as if they could hardly stand touching without dropping off the branch.

— THE monthly packet of MESSRS. CASSELL'S PERIODICAL WORKS just to hand contains the following:—Part 80 "Familiar Garden Flowers," with plate of Genista sagittalis, the Winged Broom, and Clarkia pulchella. This part also gives the title page and contents for vol. iv. and a synopsis of the genera noticed. Part 3 of "Familiar Trees" is devoted to the Plane, and has two coloured plates, one of a large tree and the other showing the catkins with foliage. Part 18 of

"Popular Gardening" contains the subject previously referred to, and has a very instructive chapter on propagation. Part 21 of the "Encyclopædic Dictionary" contains from "Cost" to "Croop," page 513 to 576. Part 18 of the "Book of Health" has, amongst other subjects, an important chapter on "Travelling and its Influence on Health." Part 42 of the "Illustrated Book of Canaries and Cage Birds" has a coloured plate of the green woodpecker, the jay, and the nuthatch with descriptive matter.

— A CORRESPONDENT writes that he has "a plant of *LILIUM AURATUM* which had thirty stems, 7 feet high, and bearing 275 flowers. The flowers were 8 inches in diameter, and the plant has not divided for eighteen years." Such a specimen is certainly remarkable, and it would be interesting to learn in what soil and position the plant is growing.

— GARDENING APPOINTMENTS.—The following appointments have been recently made through Messrs. John Laing & Co., Forest Hill Nurseries, London, S.E.:—Mr. Jas. Ford, as head gardener to Captain Elliot, Farnborough Park, Hants. The undermentioned have also been appointed through Messrs. James Carter & Co.:—Mr. Robert Leadbetter, as head gardener to A. G. Hubbuck, Esq., Elmstead Lodge, Chislehurst; and Mr. James Church, as head gardener to Sir William Parker, Bart., Melford Hall, Suffolk.

— THE Editor of the *Tropical Agriculturist* gives the following notes on THE QUEEN OF FLOWERS IN CEYLON.—"On many upland estates in Ceylon we have seen not only garden plots, but hedges brilliant with a wealth of Roses. But until the receipt of a basket from Mr. A. Whyte of Kandy, a few days ago, we had but an imperfect idea of the perfection of form, colour, and fragrance to which the very finest species of Roses can be brought in our island by careful and intelligent cultivation. When the basket was opened, a scene of exquisite beauty was suddenly revealed, the many-petalled, compact and large blossoms displaying every shade of crimson, pink, glorious golden-yellow and white. The basket was more than half filled with damp moss, and in this were placed a number of porous earthen pots which held the bouquets of Roses, the stems of the flowers being also in damp moss, with which the pots were half filled. So packed, Mr. Whyte told us, he was able to send his Roses in good condition to distances so remote from Kandy as Galle."

— A CORRESPONDENT states that a paper was lately read at a meeting in Dresden, giving an account of the INTRODUCTION OF THE POTATO INTO GERMANY and the gradual spread of its cultivation. It was first brought into Germany from Italy in 1585. The first seed Potatoes in Saxony were presented by the Landgrave of Hesse to the Elector of Saxony in 1591. In 1647 they were grown as exotics in gardens at Leipzig. They were re-introduced into Saxony from Brabant in 1717, and they were soon in general cultivation, their culture being much developed in the famine of 1770-71. In the year 1882 over nine million acres were devoted to the cultivation of Potatoes in Germany, the produce amounting to 23 million tons.

— "INSTIGATED by the threatened dearth of the Gutta Percha Tree (*Isonandra gutta*)," says the *South of India Observer*, "M. Hæckel has sought a substitute and claims to have found it in the *BIRTYROSPERMUM PARKII* (Kotschy) of Equatorial Africa, and abundant in latitudes between Upper Senegal and the Nile; especially in the forest of the Niger and Nile regions. It affects the argillaceous and ferruginous soils of Bambaris Boure and Fenoa-Djalon, where the Africans gather its fruit, which yields a grease called karite. The juice or milk is obtained by incision from the bark, and on evaporation resembles gutta percha. M. Hæckel states that he has sent seeds to various French colonies, and also to England, in the hope that the latter country will try the experiment of introducing the tree into her vast tropical possessions. M. Hæckel also calls the attention of English botanists and chemists to the divers India Bassias, as he is led by analogy to infer that they might furnish milky products similar to the *Bassia Parkii*."

— THE WEATHER. — A Westmoreland correspondent writes: "Frost has unfortunately visited us unusually early. On September 24th, at 12 P.M., the thermometer registered 8° of frost, sufficient to cut down Dahlias, Marigolds, and tender bedding plants, also Runner and Dwarf Beans. When we consider the very late spring and scorching summer no wonder that many feel this to have been a somewhat blank season, especially those who have to depend upon many such tender plants for their little display as amateurs and cottagers have to do. Single Dahlias

especially were just at their best. In 1880, September 29th and 30th were two very severe nights. At 12 P.M. on the 29th the thermometer registered 15° of frost. With these exceptions frost this year has come much earlier than usual, but in 1880 the spring was very early, and the best summer remembered in this part."

— TO KEEP AWAY SLUGS.—"Anyone troubled with slugs eating *Lapageria* growths or other choice plants," writes "E. B.," "will find Gorse cut when hard and strong in autumn and chopped into 3-inch lengths or so answers this purpose well. Spread it over the surface of the soil or between pots on stages when the plants do not touch."

— "In the many articles on the cultivation and selection of Tomatoes," writes Mr. E. Burton, "I do not notice mention of TOMATO CARTER'S RED CURRANT. More especially is this brought to my mind in consequence of the many callers here, who do not appear to be much acquainted with it. It is, as its name suggests, very similar in growth of fruit to the ordinary Red Currant, but rather more than twice the size of the finest Currants. Nothing is more esteemed here than this brisk-flavoured variety. It is eaten uncooked from salad oil, and anyone wishing to cultivate a taste for Tomatoes need only grow this. It is of free slender growth, very prolific (more so than any other), and is also particularly ornamental as a roof plant, and equally free throughout winter."

— PARAGRAPHS have been going the round of the daily and local newspapers containing marvellous accounts of the FRUITING OF *ARAUCARIA IMBRICATA* IN THE ISLE OF WIGHT, which seem to have been occasioned by a specimen of this Conifer in Steephill Castle Gardens, which is about 40 feet high and has had nearly forty cones, each twice the size of ordinary Coconuts, this season. It is not uncommon for this *Araucaria* to bear cones, and plants have been raised from seeds produced in England.

— THE PHYLLOXERA CONVENTION has been joined by Greece, and that country now forbids all trade with North and South America, Australia, Africa, the coast of Asia Minor, and Europe, except Holland, Belgium, Denmark, Sweden, and Norway in trees and plants of every kind, fresh fruits and their foliage, fruit juice, in natural or mixed state; flowering bulbs, and fresh fleshy roots of every description, Vine stakes which have been used in vineyards, and hay in bundles.

— WE regret to learn that the noted botanist M. EDMOND BOISSIER died after a very short illness on the 25th ult. at Valeyres. He was chiefly known for his "*Flora Orientalis*," but he was also the author of several other works, especially his "*Voyage Botanique dans l'Espagne*," an illustrated work which appeared at intervals from 1839 to 1845, and recounted his travels in Spain during 1837. He botanically explored various parts of South-eastern Europe and Asia Minor, and published, separately, diagnoses of the large number of undescribed species he found from within the limits of his "*Flora Orientalis*," the first volume of which appeared in 1867, and the last in 1881.

— MR. STEPHEN CASTLE, West Lynn, wishes to second "A Surrey Gardener's" proposition for the National Chrysanthemum Society to add a GRAPE CLASS IN THE JANUARY EXHIBITION. "This will meet the approval of a host of Grape-growers, the money prizes need not be large, and medals would perhaps cause greater competition. The Society offers very liberal prizes at the November Show for Apples, Pears, and Grapes, which classes have always proved very interesting to the visitors, yet while they have a special certificate for prizewinners in Chrysanthemums the fruit exhibitors are left out. I think even now it is not too late for the National to move in the matter. I should be pleased to give my support to a Grape class or classes. What say others?"

— MUCH useful work has been executed in the SINGAPORE BOTANIC GARDENS during the past year. Upwards of 70,000 forest tree nursery plants were propagated, and have been sent to the forests of Singapore, or to the forests of the neighbouring British settlements. The trees comprised Teak, Mahogany, Serayah, Gum Copal, Merbau, Toon, Illippi, Rain Tree, and mixed native trees. Of the plants sold to the public, a large number were *Fourcroya gigantea* or Mauritius Hemp; the remainder were principally ornamental trees, shrubs, Orchids, &c. "Coca" (*Erythroxylon Coca*), appears likely to prove profitable in Singapore.

— THE Committee of the York Floral Fête are endeavouring to make arrangements for holding an ANNUAL DAHLIA SHOW IN THE NORTH

OF ENGLAND, and Mr. John Wilson, the Secretary, has been entrusted with the negotiations. It is intended to offer £250 in prizes for Dahlias and other flowers, and that a guarantee fund of £400 should be formed by subscription. It is also proposed to term it the National Dahlia Show, Northern Section, and to hold the exhibition at the end of August or early in September next year, if satisfactory arrangements can be made.

— THE members of the WOOLHOPE NATURALISTS' FIELD CLUB will meet at Hereford to-day (Thursday) for their annual foray among the funguses, which will take place on Risbury Camp and the park and lawns of Hampton Court, Leominster. In the evening Dr. Bull will introduce as a subject for discussion "The Effect of Fungus in Destroying Tree Life." Dr. Bull will also give the solution of a New Zealand botanical mystery, and Mr. William Phillips, of Shrewsbury, will contribute "Some Notes on British Puff-balls."

— AN exhibition of CHRYSANTHEMUMS AT DEVIZES will be held on November 17th in the Corn Exchange of that town. It is held in connection with a bazaar, and the profits are given to a local benevolent society. The Show was promoted by the lady district visitors, but the arrangements are under the charge of Mr. Thomas King, Devizes Castle Gardens. The prizes in the fourteen classes vary from £3 to 5s., and a challenge cup is also offered for the exhibitor who gains the greatest total number of points.

— THE AYLESBURY CHRYSANTHEMUM SOCIETY will hold their exhibition on November 19th. Forty classes are provided, and the prizes in the leading classes are liberal, ranging from three guineas to 10s. The summary of accounts for 1884 shows a balance in the Society's favour of £82, which is a most satisfactory indication of the support it has received.

— CULTIVATORS of market garden crops in this country frequently have heavy losses, but they are not alone in their misfortunes, for we learn that during a recent heavy rain at Kalamazoo, Michigan, United States, PLANTATIONS OF CELERY were injured to a serious extent, the computed damage amounting to 100,000 dollars, about £20,000. Fortunately we do not find Celery suffer much from heavy rains in this country, and the plantations by the side of the Thames can frequently be seen with the water standing in the trenches.

— AN INTERNATIONAL FRUIT SHOW AT BUDA-PESTH is announced to take place October 15th to the 30th, at which money prizes and medals will be awarded. Programmes of the arrangements can be had from Wilhelm Gillemot, Gruppen Commissar, Landes Ausstellung, Buda-Pesth.

— IT is estimated that the loss to the United States through FOREST FIRES is now not less than 300,000,000 dollars a year, which is occasioned by the carelessness of boys and hunters.

— A WELL-KNOWN plant in many gardens is MAURANDYA BARCLAYANA, and a little history respecting its name given by Mr. T. Meehan in the *American Gardeners' Monthly* will therefore be interesting to some readers. Replying to an inquiry respecting the Barclayana Vine, as the plant appears to be known in the United States, Mr. Meehan observes:—"Dropping the name of genus for that of the species, it looks like a determined effort on the part of flower lovers to ignore the honour to a lady which this pretty Mexican genus was intended to establish. The author of the name, Ortega, says it is for 'Donna Catherina Pancratia Manrandy, wife of Don Augustin Juan, Professor in the Royal Botanic Garden of Carthage—a learned lady, a sharer, if not indeed a leader in her husband's botanical labours.' But all our text books give the honour to 'Dr. Maurandy, Professor of Botany in Carthage.' It is remarkable that after the botanists should have dropped the lady, ladies themselves, whom we supposed started 'Barclayana Vine,' should have also given to a man the honour intended for the Professor's wife."

ARUNDEL CASTLE.

To the student of early English history the name of Arundel is very familiar as being associated with some of the leading events occurring between the ninth and eighteenth centuries, and the venerable Castle and its gardens are also known to many readers of gardening literature; but notwithstanding this fact there are many new readers of the Journal to whom a few descriptive notes will be welcome.

Arundel Castle has been the principal residence of the Dukes of Norfolk and their ancestors for more than 800 years. The Castle has, however, a history dating from the ninth century, and it is conjectured

by eminent historians that the present "keep" (which is shown crowning the summit of a steep knoll in the centre of the engraving) was built prior to that date by the redoubtable and energetic Saxons as one of their many strongholds of defence against the incursions of the Danes. It is a remarkable structure, and although it has had to bear the vicissitudes of so many centuries, it is still in an excellent state of preservation. The immense knoll on which the keep is built was evidently thrown up by the builders as a formidable means of defence, and this was crowned with the castellated tower, the walls of which vary in thickness from 10 to 15 feet. When the Castle was under siege, and its occupants had to fly to the keep for protection, it was necessary to have a supply of water as well as food to subsist on for perhaps months and years, consequently in the centre of the keep was a well, supposed to be over 300 feet deep. During the Cromwellian wars General Waller, after vainly trying to subdue the Royalist garrison therein, mounted his guns on the tower of the parochial church, and finally succeeded in dislodging the masonry, which fell into the well, thus cutting off the water supply, and forcing the gallant defenders to yield. Local tradition affirms that the illustrious Saxon, King Alfred, dwelt here for some time, and a fireplace is still to be seen which to this day bears the latter monarch's name. Later on King John resided here.

Adjoining the keep is the ancient clock tower, built over an archway, which was originally the main entrance into the Castle.

The residential portion of the Castle is of an extensive character, which is undergoing a thorough renovation. The site of the Castle and keep is on a high position, formed partly by Nature and partly by art. The earthworks on the eastern side are thrown up to an immense height, and the gradient is so steep that it is impossible to climb without the aid of zigzag walks. The whole face of the latter is covered with ancient Oaks and other trees, and looking from the highest summit the scenery of the surrounding country is such as can scarcely be equalled. Nestling at the foot of the Castle grounds is the quaint and ancient borough of Arundel, with its overhanging upper storeys, narrow streets, town pump, and other venerable buildings, including the remains of an ancient priory, and the magnificent new Roman Catholic Cathedral, erected by the present Duke at a cost of £100,000 sterling, with the River Arun following its tortuous course through the verdant meadows and town.

Stretching far away on the verge of the horizon are the grey outlines of the Isle of Wight, to the south-east the famous South Downs of sheep fame, whilst southward may be seen the charming fishing hamlet of Littlehampton, and looking northward we behold the richly wooded park, which has a circumference of twelve miles, and is said to contain 11,000 acres. The soil of the park is very shallow, the substratum consisting of chalk. Just outside the limits of the garden is a magnificent lake known as Swanbourne Lake, which, with its surroundings, cannot be surpassed for natural beauties. This has been the favourite sketching grounds of Constable, Turner, and other famous masters of landscape painting, who have delighted to portray its beauties on canvas. Thus far we have described the interesting points of the Castle and its park, because we think its ancient history and associations, with the leading events thereof, demand more than a passing notice.

Turning to the gardens, we find these not less worthy of interest. After inspecting the Castle and other buildings, we pass through into the flower garden, which occupies the site of the ancient upper court of the Castle, and is flanked on each side by an ancient and formidable-looking wall, also at the end similarly. At this end there is a series of terraces, each about 6 feet wide, rising a few feet one above the other, with divisional walls. These are known as the ramparts, and are reached by a series of steps. Hardy plants of various kinds are planted in each of these terrace gardens, whilst the walls, which rise one above the other, are covered with Myrtles, Peach and Apricot trees, hardy Fuchsias, and Vines. As will be seen from a glance at the engraving, the beds are of a geometrical pattern, with gravel walks between. These beds are filled with hardy plants only, in accordance with the wish of the Duchess of Norfolk, who is fond of this class of plants. Beds of Lilies of various species, Tigridias, Pentstemons, Marigolds, Anemones, and other plants, looked very effective when we saw them. It is intended to do away with the present beds, which have become out of shape and crowded, and introduce a more simple and less formal style. There are some fine specimens of the topiary art in the shape of severely trained Yews, Bays, Laurustinus, &c., which will perhaps disappear with the beds, as they are sadly out of place.

Passing through the clock tower we enter the outer and more picturesque grounds of the Castle. The pleasure grounds are of considerable extent, and extend a long distance away. Rambling over the slopes and dells we come upon remarkably fine examples of noble trees. In one dell not far from the Castle we found a number of Camellias planted out and thriving. Close by, a handsome specimen of the Kentucky Coffee Tree (*Gymnocladus canadensis*), with beautiful pinnate foliage. A little farther we come upon a couple of gigantic examples of *Cupressus macrocarpa*, measuring not less than 60 feet high, and 30 feet in the spread of its lower branches. We do not know their age, but were told by our guide that they were planted by the late gardener, Mr. Wilson, who, it will be remembered, died a short time ago, after thirty years' service as chief of the Gardens. These specimens will soon be cramped for want of room, and extensive alterations will be necessary to afford such, as they are bounded on one side by an ancient road, and the other by an immense terrace, on which are growing very large trees and shrubs. A little farther on we note a few ancient-looking Mulberry trees, a fine specimen of the Judas Tree (*Cercis Siliqua-trum*), *Catalpa bignonioides*, the curious *Pavia macrostachya*, and Junipers of various kinds. The shrubberies are

FIG. 51.—ARUNDEL CASTLE, GARDEN, AND KEEP

delightful, the majority of the shrubs having attained a great size. It is remarkable how well the *Quercus Ilex* thrives on the chalk, as the trees attain an immense size, and form valuable shelters for the numerous Conifers planted here.

Continuing we come to the arboretum, which may justly be termed an historical one, as the whole of the trees have been planted by various distinguished personages. On a label in front of a fine tree of *Cedrus atlantica* we read that it was planted by the Rev. Canon Tierney in 1830; another, a sturdy pair of British Oaks, by Queen Victoria and the Prince Consort in 1846; a noble specimen of *Cryptomeria japonica* by Her Grace the late Duchess of Kent, in 1848; a large *Quercus Ilex* by the Princess Elise of Hohenlobe in 1848; a splendid pair of *Wellingtonia gigantea* by the Rev. Father Faber and the Earl of Arundel in 1859; and many others too numerous to mention here. Lying in a group on the ground in one corner of the arboretum are the remains of ancient sculptures, said to represent King Alfred and his first jury. Seed of various trees, such as the Sycamore, have, however, fallen amongst the latter, and have germinated and grown into good sized trees, consequently, unlike the system he is supposed to have primarily inaugurated, they are left to moulder and decay. We noted several fine specimens of *Pinus insignis* and *Abies Pinsapo*, but were somewhat surprised to see that *Araucaria imbricata* did not succeed.

A few minutes' walk through woodland glades, the paths of which were fringed with a continuous line of the Hart's Tongue Fern (*Scolopendrium vulgare*) with here and there a break in the foliage revealing the charming scenery of the beautifully undulated and diversified park, and the pellucid water of Swanbourne Lake reflecting the shadow of the adjacent foliage, as in a mirror, at our feet, we arrive at the dairy garden, so called from the close proximity of the ducal dairy, which has gained more than a local fame as a handsomely built and fitted structure. The garden surrounding the dairy is kept very neatly, there being a number of tastefully arranged beds of bright showy flowers. There are also several very large specimens of *Magnolia grandiflora*. The situation in which they are growing is a damp one, being close to the banks of the river Arun, hence why they grow so freely, this species being a native of the swampy regions of North Carolina. A little further on is a fruit and vegetable garden, used chiefly for growing the culinary kinds of fruit and coarse vegetables. There are also close by several small ponds made for the purpose of collecting ice.

Leaving this farther limit of the gardens we have to cross a public road which passes along the base of the Castle heights, enter a door, and ascend the latter by means of a zigzag walk, a task not easily accomplished, and passing across the Castle grounds we arrive at the principal fruit and vegetable gardens. The fruit garden is about two acres in extent, and is thickly planted with venerable-looking Apples and Pears, Filbert, Plum, and Fig trees. Many of the former are in the last stage of decay. There is a dense undergrowth of Currant and Gooseberry trees, which we were told were not very profitable, and it is the intention to renovate this ancient fruit garden or orchard by removing the Currants and Gooseberry trees and allowing the larger trees to have the full benefit of the soil. Some Brown Turkey Figs were carrying a capital crop of fruit, which were just beginning to ripen in the early part of September. In an out-of-the-way corner of this garden a large and lofty orangery has been built. The designing of this building was entrusted to the architect of the estate, and, as is generally the result in such cases, a structure is built wholly unsuitable to the growth of plants. The sides and portions of the ends, with the exceptions of long narrow windows in the south side, is built with brick. The sides run up to a great height, consequently the roof is lofty, which, although glazed with glass, has such massive timber used in its construction as to exclude the greater part of the light so essential to the growth of plants. The back wall was proposed to be covered with creepers, but no provision was made for this when the heating apparatus was fixed, as the pipes occupy the width of the path which runs close to the wall.

Descending a steep gradient through a tunnel we find ourselves in the principal vegetable garden. This contains about seven acres, and is only walled in on one side—the south—planted with large, healthy, and free-fruited examples of Amsden June, Goshawk, and Royal George Peaches, and Pine Apple and other Nectarines. Large plots of Celery, Brassicas, Potatoes, and other useful and indispensable crops were looking in the best possible condition, although the roots of the adjoining Elms are such arrant robbers of the virtues of the soil. Heavily laden trees of Golden Pippin and other useful Apples were growing on each side of the walks. Within a few yards of the latter is another smaller vegetable garden devoted principally to growing Strawberries. In this enclosure, too, are the plant and fruit houses. The majority of the houses are not of modern construction. There is an old Peach house containing veteran trees of Royal George and Noblesse and a couple of Pine pits in course of repair. There are also a couple of large span-roof metallic vineries, said to have been built over sixty years ago and still as sound as ever, in which fair crops of late Grapes were ripening; a couple of metallic lean-to's containing Muscats and Hamburgs; a couple of wooden lean-to's in which the earliest crops had been growing, and a lean-to metallic Peach house.

The plant houses are not numerous, but nevertheless there is a heavy demand on their resources in the way of keeping up a daily supply of cut flowers for the decoration of the altar in the Cathedral, which is within a stone's throw. One house is devoted to Eucharis. The plants looked wonderfully healthy and free from disease, and as a constant supply of these flowers has to be kept up it requires more than ordinary skill to manage to attain this object. *Stephanotis*, the Elvaston variety, is largely grown here; also *Gardenias*. These were planted out and

doing well. Smaller houses were filled with all sorts of useful plants for decorative purposes, and pits of Violets, Poinsettias, Primulas, and Cinerarias. Strawberries are forced here to the extent of 3000 plants, the favourite varieties being Dr. More, James Veitch, and the Vicomtesse. Hard by is a large specimen of Fig known as the Petworth variety, but although it fruits so freely it has never ripened one out of doors. A similarly large specimen grown at Petworth under glass bears abundantly, and the fruit is said to be very delicious. Our best thanks are tendered to Mr. Burberry for the great kindness he showed in making our visit a pleasant and interesting one.—T. W. S.

JUDGING GRAPES.

I PERFECTLY agree with all Mr. Iggulden has written on the above subject, and the only addition I thought necessary to make those comments perfect was that he should add Muscat Hamburg among the varieties to be in season during July and August.

I think it is almost hopeless to look for the framers of prize schedules to state that only particular varieties are admissible in certain seasons, as that would be the means of deterring such exhibitors as could not comply with them from exhibiting altogether, which is the farthest from the desire of such committees, their object being to produce as good a show as possible with the small means at command. I perfectly agree with keeping a class for Black Hamburgs, and a class for any other black variety, and the corresponding class for Muscat of Alexandria and any other white variety. I once had the good fortune in contending the point against an overwhelming majority as to the desirability of making these four classes, to have the satisfaction of seeing it adopted. I think exhibitions of very moderate pretension should endeavour to provide these four classes, as Mr. Iggulden justly remarked. Where classes are offered for each variety, of course the work of judging is simplified, but it is not in the power of many societies to do thus; and perhaps it is not always a matter of regret that they do not, for where handsome prizes are not offered to attract exhibitors from a distance, very poor examples indeed will sometimes carry off leading honours. A considerable scope in the case of the generality of Grape classes must be given to the judges to use their own discretion, and for my part the man who holds Mr. Iggulden's ideas is the one I should prefer to judge my exhibits.

Your correspondent "S," page 268, seems quite to have left out Mr. Iggulden's mention of the Chrysanthemum shows as being the best opportunity of exhibiting late Grapes, and surely there are enough of them springing up in different parts of the country to satisfy anyone. I should hardly think "S." exhibits very much, or he would never think of securing for himself the Grapes, or whatever else he may stage. I think such expressions are calculated to prejudice employers against exhibiting, and if "S.'s" employer does not mind him taking for himself the produce he exhibits, I feel sure he is almost, or quite, alone in that matter.

Judging from the whole of "S.'s" remarks, it would appear that he wishes to encourage the growth of late Grapes for summer and early autumn shows, and he would have the judges take into consideration that they would be good six months hence, and all that they have to look at now is, Are these Gros Colmans or Alicantes finer in bunch or berry, of a more symmetrical outline, better colour and bloom, than So-and-so's Black Hamburgs and another's Madresfield Court, and if so they are entitled to the first place? If this was the only course of judging adopted at July and August shows, I think we should less often meet with Black Hamburg and Madresfield Court. For my part I should like to see a special class for Muscat Hamburg in the schedules of horticultural shows to encourage the growth of high-flavoured varieties, and not that constant craving for appearance only.—C. WARDEN.

[We think that if there were such a phenomenon as a gardener "securing for himself" the Grapes of his employer after exhibiting them, he would scarcely proclaim the fact in a public journal. "S." is quite correct in stating that many Grapes are shown that are never intended for their owner's table, as they are sold with the immediate sanction and by the request of those whose property they are. This is the plain meaning of the remarks on which our correspondent has put a different interpretation.]

THIS important subject seems to be attracting the attention it deserves, and if any alterations can be made in prize schedules which will afford satisfaction to those writers who seem to think that such will be beneficial generally, it is to be hoped that the outcome of the present expression of opinions may be that they will be carried through without delay. I for one fail to see how autumn shows can be carried on without prizes for such widely and largely grown varieties as Gros Colman, Lady Downe's, and Alicante being offered. There are other varieties, such as Gros Maroc, Alnwick Seedling, Mrs. Pince, Gros Guillaume, &c., which are not at their best at autumn shows. Are all these to be excluded from September shows? If the rule laid down by some writers is to be strictly carried out, all the aforementioned Grapes should not be seen on our exhibition tables till November at the earliest, and some of them not till much later on in the season. Are there shows enough held from November to March at which all who desire to show can have opportunities of doing so? Are there enough prizes offered in the country generally during these months at what few shows are held then to enable growers to withstand the temptations offered at shows held at the end of August and September?

Until we have prize schedules entirely re-arranged, all late Grapes excluded from autumn shows, and other opportunities offered for their

displayed at times when they are in greater perfection as regards dessert qualities, we must expect growers to bring forward their Alicantes, Gros Colman, Lady Downe's, &c., and cannot wonder if they should exclaim against being put in the background simply because time alone is wanting to make them perfect.

"A Kitchen Gardener" defends Alicante vigorously, and ably states his reasons for so doing. There can be no doubt that what he says is true. Alicante is, and ever will be, I think, more generally grown than Madresfield Court; it is a free cropper, a fine free grower, and grand keeper, and its qualities of bloom, bunch, and berry have been so often displayed at shows that they must be patent to all. It has no fault of cracking to perplex and annoy, and though not possessed of the flavour which Madresfield Court attains, is still by no means to be despised for that, as it has a peculiar crispness, which makes it, when used in January, February, and March, very pleasant and refreshing.

I can endorse "A Kitchen Gardener's" remark on the colouring of Grapes this season, at least in regard to some varieties. Gros Colman has coloured much more quickly than for some seasons back, and that with an extra heavy crop. If "A Kitchen Gardener" had seen a bunch of Duke of Buccleuch which Mr. Kirk exhibited at Edinburgh lately he would have seen one the very reverse of "ragged and small." The bunch was large and the berries enormous. Indeed all the Duke of Buccleuch shown there was characterised by the solid appearance of the bunches and the regularity of the swelling of the berries.

Golden Champion was also far from "ragged;" it, too, was compact and regular.

Mr. Jenkins remarks that it is a pity "that prizes are not offered solely for Madresfield Court at our summer shows." Certainly it is a pity if this is not done, and all societies really anxious that Grapes should be shown "in season" should do so. Mr. Jenkins also remarks that by so doing societies "would greatly encourage growers to persevere with it;" and also that "many who have almost lost heart on account of the berries splitting, would, by paying more attention to atmospheric conditions, eventually succeed." If such can be effected by means of societies offering prizes "solely for Madresfield Court" at the summer shows it is to be hoped that all will speedily do so.

The question of the division of Grapes into summer, autumn, winter, and spring varieties at our shows must be taken up and carefully considered if opinions such as those expressed by Mr. Iggulden and others are to prevail. Hard-and-fast "rules and regulations" as to when each particular kind is to be shown must be laid down, and who will be able to do this in such a manner as will please all? I am afraid that some latitude must always be allowed, and where there are Grapes shown superior in every respect save their condition for the dessert table—which time alone is required to remedy—to others more "in season," then the word should be in favour of the former.

"A Kitchen Gardener" has made this plain enough in his remarks on "A Young Exhibitor's" ideas. As he says, shows would need to be held far more frequently than at present if "A Young Exhibitor's" ideas of "in season" and "out of season" are to be acted upon. Many able gardeners and first-class Grape-growers have in times past adjudicated at hundreds of shows where common sense guided them in their awards, where no hard-and-fast line of being "in season" was allowed to warp the judgment, but where, every condition being duly weighed, results satisfactory to the majority of exhibitors were arrived at. A very great change indeed will have taken place if in the future all late Grapes are debarred from autumn shows, as some writers seem to desire.—S.

I THINK Mr. Iggulden and a few others are writing too strongly against the Alicante Grape and giving too much praise to Madresfield Court. It is only in a few places that Madresfield Court does well, otherwise we should see it oftener at our shows. We all know it is a good Grape when well done, but seldom do we see it. And why should a had example of that Grape be placed before others? My advice would be to beginners, Plant ten Alicantes to one Madresfield Court if a quantity of good Grapes is wanted. In eight localities out of ten Madresfield Court will not do well. I have grown it here for ten years and tried it in different ways. I have not yet been able to cut a bunch fit for our local show. I have six other varieties in the same house, and have exhibited bunches from each of them; the Alicante proves the best. I start my house the 1st of February. I should like to know if Alicantes are not fit for exhibition in August when started at the time named. If we follow Mr. Iggulden he will shut out all who have only a house or two at their command, and give scope to those gardeners who have many houses, almost enough to grow each variety of Grape separately. The gardener who has only space to grow a few hundredweight of Grapes has to compete with those that grow Grapes by the ton.—H.

"MODIFIED" EXTENSION VINE TRAINING.

THE claim put forward this week by "J. W." on Mr. Taylor's behalf, that he is only "a modified" extensionist, will not "hold water." He is by his own showing "a confirmed extensionist." He mentions 12 feet in his book as the length of cane that may be left at pruning time, and he clinches the case by declaring that "cutting down the stem of a Vine does not add to the vigour of the growth." Of course, no extensionist approves of the practice unless the wood is well ripened. That was laid down as an essential condition of the extension system long before Mr. Taylor wrote a word on the subject, and that condition really goes to the bottom of the matter, because (except in cases where it is a matter of

accommodation or convenience) if a Vine is well ripened here is no limit to the length of cane that may be left. Why should not 20 or 30 feet be left as well as half a dozen or 12 feet? The logic of the argument is clear and undisputable, and practice has proved its correctness.—J. S. W.

TUBEROUS BEGONIAS OUT OF DOORS.

It is often regretted that more diversity is not introduced in the bedding decoration of parks, public and private gardens, but it seems that at least one group of plants has not yet been employed to the best advantage for this purpose. Tuberous Begonias have been frequently recommended in the past few years for bedding out, but their merits have not been fully recognised at present; and though they have obtained a prominent position in public favour as greenhouse or conservatory plants, they are yet regarded by many as of doubtful value for beds or borders out of doors. This is quite a mistake, for the plants are evidently well adapted for such a use throughout the greater part of Britain. We have seen them in many districts of England and Scotland, but as examples two widely separated gardens may be noted—namely, Drummond Castle in Perthshire, and Heytesbury in Wiltshire, for in both of these we have seen admirable beds of brilliantly coloured Tuberous Begonias at a time when the beauty of the Pelargoniums was waning. In both wet and dry climates these Begonias succeed, for the succulence of the stems enables them to resist more drought than many other plants, while rain does not seem to injure them in the slightest. In heavy storms the flowers droop slightly, so that the rain runs off the outer surface of the petals without affecting the colour. It is remarkable that such plants should endure excessive rain so well, but it has been abundantly proved, and it is one of the strong points in their character.

Few who have not seen the Begonias in beds at Messrs. J. Laing and Co.'s Forest Hill nurseries this season could form an adequate idea of the wonderful effect produced by 90,000 plants in flower. Scores of beds 100 feet long and about 4 feet wide were closely packed with seedling Begonias in separate colours, formed a display which, for brilliancy and richness of colouring, could not be equalled by any other plants at the end of September. A most important step towards popularising these plants has been made in procuring fixed strains of different colours which can be depended upon to come true. Messrs. Laing & Co. have now twelve shades—namely, rose, pink, scarlet, crimson, dark crimson, white, yellow, bronze, orange scarlet, violet red, blush, and crimson red, and they have had huge beds of each that showed most satisfactorily how true they were to their respective colours. Another interesting point was the time required to produce such vigorous flower-laden plants as those named. The seed was sown in heat on January 20th this year, and after the usual gradations of pricking off and potting, the seedlings were ready for planting out the first and second week in June. The soil is naturally heavy, but it received no special attention beyond a top-dressing of road sweepings, old manure, and cocoa-nut fibre, in which the plants were placed, and there during July, August, and September they produced their massive flowers in thousands. It is found, however, that the seedlings flower even better the second season, as they then assume their best characters of colour and floral size, and if any are left after the enormous demand is satisfied, we may expect to see some still more beautiful beds next year.

As to the general quality of the varieties it is almost needless to speak, for so much attention has been paid to Tuberous Begonias at Forest Hill during recent years that it is difficult to imagine how they can be farther improved. Nine-tenths of these seedlings are as good in size, substance, and form of flowers as varieties which a few years ago were named and certificated, amongst them many being observable that even now seem worthy of designations. Those, however, that are now honoured in this way must be superlatively good, and Mr. Laing has a Royal Family group of what he considers his finest varieties, and of which a handsome coloured plate is being prepared. These constitute the types of the highest development in Tuberous Begonias, the flowers being finely rounded, the petals nearly equal in size, and forming a beautiful even outline. The varieties are named Queen Victoria, Prince of Wales, Princess of Wales, Duke of Edinburgh, Duchess of Edinburgh, and Prince Albert Victor, and the colours are extremely rich shades of rosy salmon, dark maroon, bronze yellow, scarlet, orange scarlet, and violet rose. The last-named tint, which distinguishes the Princess of Wales, is a decided step towards purple or violet, and it seems as if there might be some chance of obtaining that desideratum, although experiments have not hitherto been very satisfactory.

The named varieties, both single and double, raised in the last two or three years are very numerous, and their merits are testified by the first-class certificates awarded for them at the leading horticultural shows in Great Britain.

POTATO MAGNUM BONUM.

I SENT you yesterday a small box containing five Potatoes, Magnum Bonum. When I weighed the five the weight was exactly 8½ lbs, the largest being 1 lb. 3½ ozs. I have read so much about the Potato crop being almost a failure in some parts, that I thought it might interest you to know that on our heavy lands we have a magnificent crop, though, of course, owing the early and lasting drought, followed by warm rain, the shape of the tubers is not all that could be desired. I have harvested about 2½ tons—2 tons of Magnum Bonums, half a ton of Bresee's Prolific, a variety well suited for our soil and situation. Soil, a stiff whitish clay;

situation, high; land with a steep slope facing south and south-west.—
JOHN A. WILLIAMS, *Alderminster Lodge, Stratford-on-Avon.*

[The tubers were wonderfully fine, not hollow, and they cooked well, one that was baked proving particularly good.]

CROWN ANEMONES.

WRITING to the *Times* respecting the above plants Mr. F. W. Burbidge thus describes his method of treatment. "The many variations of the *Anemone coronaria* are so universally thought of as spring flowers only that, in the interest of a rapidly increasing class of amateur gardeners, I wish to say that they flower most luxuriantly at the present season in many localities if the precaution be taken of raising plants from seeds sown in the open air in early spring. Gardening has been described as an art 'which does mend Nature; change it rather;' and so it comes that in mild localities near the sea this Windflower of the Greeks may add beauty to our gardens in this, the Dahlia, season, even if not also in company with the Chrysanthemum and the Christmas Rose.

"The ordinary method of *Anemone* culture now practised in most gardens is confined to the autumnal planting of French or Dutch-grown roots for blooming during the following spring days, and this plan, if not actually 'as old as the hills,' dates from the days of Shakespeare. Parkinson, in his '*Paradisus*,' published in 1629, indeed tells us that the spring-blooming *Anemones* vary as much from seeds as do the Tulips; but, as far as I have been able to gather from books, no attempt was made in the olden days to treat the Crown *Anemone* as an autumnal-flowering plant, as is now quite possible. There is no magic in the method I recommend. The woolly seeds are rubbed up together with dry sand or earth so as to separate them thoroughly, and during February or early in March they are sown very thinly on a bed of earth well enriched below the surface with cowdung, the seed and sand being sprinkled on the surface together. After sowing, water during dry weather, and when the seedlings appear thin them so that those remaining are fully 6 inches apart. During July and August the growth of the young plants may be strengthened by the application of weak liquid manure or soot water. The first flowers begin to appear during September and October, or say seven months after the seeds are sown, and near the seashore or in warm sheltered localities flowers are produced during mild weather all through the winter months, the finest flush of blossoms coming in March and April.

"The flowers sent herewith are pulled from a seed bed sown so late as March last. This system of obtaining brilliant flowers of the Crown *Anemone* during the autumnal and winter months is so ample, and the results so satisfying, that it seems to me to merit the attention of flower-loving amateurs.

"In former years our finest Pears were reared from seeds in Belgium; even the garden varieties of our national emblem, the Rose, were reared for us in France, and now our bulbous flower-roots come from Holland. But foreign competition has, of late, taught us many things, and so to-day we at least know that it is possible to raise the finest of fruits and of flower-roots on English soil. English varieties of Queen Rosa now equal, even if they do not surpass, others; and last, but not least, it is fairly proven that the same statement is true in the case of the double and semi-double varieties of the Crown *Anemone*."

EFFECTS OF EARLY PRUNING ON VINES.

In the *Journal* of September 24th, page 274, there is an article on the above subject by your valuable correspondent, Mr. Iggulden, which will interest all those who are in the way of showing Grapes, as well as that greater number who are in the habit of shortening laterals. I will venture to say that there has already been many a spur marked from which part of the lateral has been cut with the bunch, and not a few will remember that it was but last week they shortened the laterals in a vinery in order that they might let in more light to the Chrysanthemums that have to be put inside.

From what I can gather from Mr. Iggulden's article he is of opinion that the practice of shortening laterals to about 6 inches or so is injurious to the Vine, and in support of this he mentions a case where the Vines in the centre of a Muscat house had been heavily cropped, and a considerable number of bunches were cut therefrom with parts of the laterals attached to the bunches; the result in the following year being that the Vines made a weak break, and the cause of this is attributed to the shortening of the laterals. Now, I think it would have been more reasonable to attribute the cause of the weak break to the heavy cropping of the Vines instead of the shortening of the laterals. It seems to me that this case does not support his views, because we have always the heavy crop to be considered. I have not given the subject as much attention as Mr. Iggulden has done—

—judging from what he says his observations have been for "the past three seasons," but this I can truthfully assert that in a certain early vinery where Grapes are grown for the market the laterals are always shortened to about 6 inches, "while yet the Vines are in full leaf." The Vines are about nine years old, and this year they finished what any reasonable individual would call a splendid crop, and certainly showed no signs of that "slowly" going to ruin which Mr. Iggulden would expect to see. Again, I am acquainted with a somewhat famous house of Vines where there are from fifteen to twenty bunches of Grapes cut for exhibition every year, having of course a good piece of the lateral along with them. Now, all this being cut from some ten rods yearly ought, according to Mr. Iggulden, to be telling upon them, as it has been going on for at least five years. But instead of their falling off I see this year's beautiful crop being praised in the *Journal of Horticulture*.

The subject, I think, is a most important one; for if it can be proved that shortening laterals at this stage is weakening to the Vines, there are thousands of gardeners about this time who will be injuring their Vines, but if it does no harm those who practise it and find no evil results would do well to give us their experience, as the shortening of laterals is very serviceable where space for winter-flowering plants is limited.—R. GILCHRIST.

THE PRIMULA CONFERENCE.

FROM a copy of the programme of the Primula Conference, to be held on the 24th of April, 1886, under the auspices of the Royal Horticultural Society, it appears that an exhibition of these interesting plants will be held in the conservatory at South Kensington on the 23rd and 24th of April, 1886, in conjunction with the Exhibition of the National Auricula Society. The President of the Conference, John T. D. Llewelyn, F.L.S., and the Chairman of the Committee, Dr. Michael Foster, F.R.S., are supported by a numerous Committee of gentlemen interested in the subject in this country, both amateur and professional, as well as by the representatives of a large number of the chief botanical and horticultural gardens and museums abroad. It is proposed that the plants to be exhibited shall be arranged under eleven classes—namely, I. The Primula. II. The Primrose and Polyanthus. III. Varieties of *Primula Sieboldi*. IV. Varieties of *Primula sinensis*. V. European species, varieties, and hybrids of the genus *Primula*. VI. Himalayan and other Asiatic ditto. VII. Chinese and Japanese ditto. VIII. American ditto. IX. Plants allied to the genus *Primula*, such as *Cyclamen*, *Dodecatheon*, *Androsace*, *Cortusa*, &c., of the species only, not garden varieties, will be admitted. X. Primulaceous plants grown to illustrate special modes of culture, &c. XI. Specimens, models, and drawings illustrative of the structure and mode of growth of Primulaceous plants.

In order to assist in the arrangement of the European Primulas at the Exhibition, Mr. J. G. Baker, F.R.S., has kindly drawn up for the Committee a list of European Primulas, classified in three groups, published as an appendix to the programme, which may serve as a preliminary basis for the discussion at the Conference, and also as a guide, as far as possible, to the exhibitors in giving names to the plants they exhibit.

The provisional programme of the Conference on April 24th, 1886, includes—1, The origin and history of the florist's Auricula, on which subject an introductory paper will be read by Mr. Shirley Hibberd. 2, The directions in which efforts should be made with the view of improving the florist's flowers belonging to the genus *Primula*; introductory paper by Samuel Barlow, Esq., J.P. 3, The nomenclature of Alpine Primulas; introductory paper by Mr. J. G. Baker. 4, Culture of hardy Primulas; introductory paper by Dr. Maxwell T. Masters on root structure and mode of growth as affording indications of the probable best culture.

This Conference following closely, as it does, on the heels of the Apple Congress and the Orchid Conference, and with a Pear Congress in course of arrangement, together with the active part being taken by the Society in housing and caring for growing plants to be shown in the forthcoming Colonial and Indian Exhibition by the various colonies, gives evidence that the Royal Horticultural Society, under the energetic management of the present Council, not only still holds, but has taken a step in advance of its well-known position as the horticultural authority in this country.

FERNS IN VINERIES.

I AM no advocate for filling vineries with plants, yet having a partiality for Ferns I grow a few, which improve the appearance of the houses. The vineries being 20 feet wide I have a row on each side, and these being 8 feet from the stems of Vines I am not afraid of their conveying insects to the Vines. The culture of Ferns is very simple, and

they do well under the shade of Vines. Having but little fire heat after Christmas it is late in spring before I get a good young growth, but they are potted in April or May, using a good portion of loam. We never repot a Fern until it is growing. The following are what I am growing, and they are doing well:—*Dicksonia antarctica*, two young plants, are pretty, though they are inclined to be affected by thrips; how long they will do here I do not know, but in a young state they are very useful decorative plants. *Blechnum brasiliense*, the most perfect plant I have, this wants room to show it off, so I stand it at the end of the house on a tub. The *Adiantums* are very useful. *A. cuneatum*, so well known, is always a favourite. I thought at one time *gracillimum* would supersede it, especially for bouquet and buttonhole work, but I find it is not so. Both are useful either as dinner-table or vase plants. *A. decorum* is, however, by far the most useful in small pots, say 48's. *A. concinnum latum* is another noble-looking erect variety with much larger fronds than the preceding. *A. farleyense*, very beautiful, but I have great difficulty in keeping it through the winter; this requires higher temperature than I can give it. *A. Legrandi* is more curious than beautiful, and if the foliage is kept dry it will do. *A. tinetum* is always very pretty, its pink tints on young fronds making it very distinct; its habit, however, is rather loose and straggling. *A. Paccottii* is my favourite. One of the best of the later introductions, it should be in every collection; it appears to be hardy, and its growth is very compact, of a dark green. *A. mundulum* is very dwarf and distinct, making good bushy plants in small pots. *Adiantum fulvum* is quite distinct from any I have named, and is a useful hardy variety.

Asplenium Hookerianum is a very pretty graceful plant, very distinct and useful. *Lomaria gibba* is too well known to need praise from me. This is very effective for general use, the only time it looks shabby is when the fertile fronds go off. *Lastrea aristata variegata* is a fine companion for *Pteris argyrea*. *Pteris tremula* is a free-growing Fern, very useful for so many purposes. *Lastrea prolifica* is a decided curiosity, and free in growth. *Asplenium bulbiferum*, though old, should not be lost sight of, it being useful either as large or small plants. *Nephrolepis exaltata* is another well worth growing in a collection. *Cyrtomium falcatum* is a very bright dark green large-growing variety, hardy, useful for halls and lobbies. *Nephrodium molle corymbiferum* is distinct and hardy. *Pteris cretica* is a well-known useful Fern. *Pteris cretica albo-lineata*, the variegated form of the above, is distinct and free in growth. *Pteris serrulata* is common, but indispensable in a collection. *Pteris serrulata cristata*, the crested form, very dwarf and pretty. *Aspidium trifoliatum* is worth growing for the sake of its fernlike fronds.

All the above do well, the unsatisfactory varieties being omitted.

With the Ferns *Asparagus plumosus nanus* succeeds well, being easy to grow and very telling in a collection. The cut shoots and branchlets are very lasting. Do not err in potting the plants too soon, let them be in full active growth before potting or dividing.—STEPHEN CASTLE.

THE SOUTHWELL NURSERIES, NEAR NOTTINGHAM.

SOUTHWELL is easily reached from Nottingham on the Retford and Lincoln line, and the good old minster is well worthy of a visit. Close to the town is Mr. Merryweather's extensive nurseries, which the rosarians of the district know so well, and where Roses are grown by the thousand, and Tea Roses out of doors are most extensively cultivated and thrive well. Towards the end of September the Teas were in great beauty and flowering profusely. The Roses are also largely grown under glass there, and Mr. Merryweather has a large stock of the beautiful new Tea *Etendard de Jeanne d'Arc*, which under glass is veritably a white *Gloire de Dijon* of great beauty and of excellent habit, whilst out of doors it grows well and flowers most profusely, but in the open air affects greatly the type and appearance of *Souvenir de la Malmaison*. *Sunset* is another favourite, an improved *Madame Falcot*; and *Madame de Watteville*, a very lovely Rose of *Homère* style. *Princess of Wales*, extra fine; *Miss Edith Giffard*, *Innocente de Pirola*, and climbing *Madame Eugène Verdier* are all regarded here with great favour. The new Rose *Henry Bennett* is not regarded with favour, and judging from a bloom I saw it will not take a high place amongst our Teas, a class of Roses which is now very rich indeed in fine varieties.

Hardy ornamental trees and shrubs are extensively grown, and fruit trees, especially Apples, are grown in large quantities, the Southwell and Halam districts containing extensive Apple orchards. There is a remarkably productive fine variety peculiar to this district, and said to have been raised there, named *Bramley's Seedling*, and I believe it obtained a special distinction at the Apple Congress. It is undoubtedly a very first-class variety of stiff close habit, with healthy distinct foliage, an enormous and certain cropper, and everybody's Apple. It is all that can be desired in quality and grows to a good size. Herbaceous plants also secure here more than ordinary attention, and a very fine collection is well cultivated. I noticed a pretty and seldom met with plant, *Hypericum Coris*, with its Heath-like habit and charming yellow flowers. *Helianthus multiflorus major*, one of the finest of all the single perennial Sunflowers, and *Veronica subsessilis* are two very desirable border plants. *Montbretia Pottsi*, with its bright orange slender spikes, was very bright and beautiful. *Lobelia syphilitica* was at home and in full beauty, and a mass of *Rudbeckia Newmanii* showed what a grand thing it is for autumn decoration, especially in masses, and yet it is an old plant not known as it should be. Mr. Merryweather speaks highly of Mr. Ingram's *Saxifraga ligulata* as a decorative plant, a strong-growing variety, but it blooms earlier in the year. Two large beds of *Saxifraga granulata flore-pleno* in luxuriant growth must be a sight in the spring.

Spring-bedding plants are cultivated here, and a very large stock of double hardy Primulas grow well here, and a good collection of Alpine and other hardy Primulas do so well here. Pansies do well, as also do Violas, that fine variety *Countess of Kintore* being a special favourite. Violets luxuriate, and all the newer varieties, as well as the older ones, are grown here largely; but Mr. Merryweather places a very high value as a market variety upon *Willsiana*, sent out from Slough, a close erect-growing variety of excellent habit, with large single blue flowers, and a fine pot or frame variety. Amongst the doubles *Comte de Brazza* and *Marie Louise* are the favourites here. That very fine double variety *Lady Hume Campbell*, which is a special favourite at Harefield Grove, near to Lady Hume Campbell's estate, and is a great improvement on the old *Neapolitan*, and of the same habit and colour, is to be added. Altogether the Southwell Nurseries afford an excellent opportunity to old hardy-plant lovers of brushing up their memories and reviving old associations by seeing so many of our finest, and in many instances rare old favourites in the plant world.—VIOLEA.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 4.

AN appeal was recently made to the Duke of Westminster, as the freeholder, to secure the opening to the public, at least in the dull season of London, of those West End squares that are situate in what is styled Belgravia. As far as the inhabitants of Westminster are concerned, they might be said to have some ancient right to enter the enclosures now so jealously guarded from the commonalty, for they occupy part of the open space that during some centuries was free to the Westminster folks, young and old, for some months of the year, and was commonly known as the "Five Fields." At the present time the people of the districts near Belgravia cannot be said to be badly off for open spaces, with the wide range of West End parks and Battersea Park within easy access. Out of deference to the wishes of the privileged, however, the Duke had to refuse, although personally willing, but an exception was made in respect to one-half of the central plots of Grosvenor Gardens, which is opened temporarily.

The Five Fields, which yielded to mansions and gardens soon after George III. ceased to reign, have left us little or no traces of their former history. Their boundaries are lost; we only know they were situate north of Ebury Street towards Knightsbridge, the now hidden streamlet, the Westbourne, flowing between them and Chelsea, crossed by a bridge of mere planks, called "Bloody Bridge," as associated with some act of violence committed by the robbers who lurked at night behind its sand or mudbanks. There was a Willow Walk, too, but the soil does not favour at present the growth of this tree, which, unfortunately, graceful as it is in its different kinds, can but seldom be induced to grow about the metropolis, because it wants much moisture and dislikes smoke. I once hoped to find in some of the squares, after the ground had been turned over, specimens of the wild Clary (*Salvia verbeniaca*) or the Bitter Cress (probably *Cardamine hirsutum*), which it is recorded the old herbalists plucked in the Five Fields, but they did not appear. Though to my surprise I found the Red Valerian (*Centranthus ruber*), only a straggler it is true, yet possibly it formerly grew on the higher slopes of this ground, just as we now see it sometimes along railway banks, chiefly in chalky districts. This open space seems to have been a part of the farmland of Ebury or Aybery, and Lammass-land, that is open in some months of the year and closed during others. Towards Knightsbridge, however, and about the site of Belgrave Square was ground always under cultivation by the Chelsea gardeners of the Georgian times, where they raised such vegetables as Melons and Asparagus, the soil being formerly suitable for them and other plants that are lovers of moisture. The last vegetable I saw flourishing under culture in Belgravian bounds was—Rhubarb!

To proceed. Grosvenor Gardens, then, small in extent, is as yet the only West End square free to all (at least it is in August and September), but under some singular regulations, for one thing "shouting" is prohibited within its sacred limits, as well as speech-making. Not a space much resorted to by the poorer class, it offers to any semi-suffocated passenger who has just emerged at Victoria Station from the miseries of underground travelling, a spot where he can breathe a purer air and gaze on greenery. Wisely but a small number of trees have been planted. A double row of young Sycamores cross the centre from north to south; probably these in time will prove to be too near each other, close planting being often noticeable about London, I suppose for the reason that some are sure to die off. But Sycamores do not look well if placed too near together, owing to the size of the leaf, and on the whole it is a species that bears a London life better than many trees. Here is a central bed, with a moderate display of summer flowers, and paths run off from the centre at

right angles to the four points of the compass, the corner spaces thus made are occupied by grass plots. These paths are edged with Ivy, according to a fashion much favoured by the layers-out of town gardens, and all round the garden is a fringe of shrubs, amongst which Lilacs and Hollies predominate.

Eaton Square, without going into exact measurements, may claim, I believe, to be one of the largest of the metropolitan squares, and its open ground is divided into six parts, the two central gardens being the larger, and through it runs the King's Road, extending on to Fulham, and along which in former times were the many nurseries of Chelsea, all of which have succumbed to the builder save Little's Nursery; this, though closed, is not yet turned into rows of houses. An examination of the trees of this square shows pretty conclusively that none of them are older than 1827 or '28, when the ground was laid out, so that possibly this part of the Five Fields did deserve the title of "barren waste," bestowed upon it by a poetaster of last century. Towards Knightsbridge there were old trees scattered here and there. The three large Sycamores of Chesham Place must have been planted before the houses were built; so, too, several scattered about Belgrave Square, and there are memories of ancient Elms of Stuart times which have perished through insect enemies. For many years Eaton Square has been noticeable for its Almond blossoms of the early year, and its Laburnums and pink "Mays" of a more advanced season; but lately the Almonds have been scant of flowers, and the Hawthorns, pink and white, being mostly near the railings, have suffered from those meddlesome youngsters who do needless damage to obtain flowers. The gardens on the north side of this square have more trees than those on the south; as one consequence the grass there appears to be more patchy. Probably of all British trees the Ash exercises a most obvious influence upon the plants that may happen to come under its shade, and though Tennyson in one of his poems, referring to the signs of spring, says that "thick by Ashen roots the Violets grow," this is a mere fancy; one seldom finds any wild flowers near Ash trees. Yet the species is suitable for town gardens, because it keeps in leaf when the Elm and Horse Chestnut are bare, when the Lime shows only a few fresh leaves put forth at the end of summer, and even the Sycamore has lost the greater part of its foliage. There are many Ash trees in Eaton Square, and some were placed in the midst of grass plots with seats round them, and as a consequence the grass languishes. It would have been better to have had a circle of gravel about the trees, some of which are remarkably fine. There are also well-grown Sycamores and Limes; the Horse Chestnuts and Elms are fewer; the numerous Lilacs appear to be greatly the sufferers from insect pests. Privet hedges surround these squares, and the gardeners have been so fond of this shrub that they have set bushes besides in the nooks and corners amongst other evergreens, which, however, are not abundant or much varied. The beautiful and large caterpillar of the Privet hawk moth used to be seen frequently running itself on the hedges in August and September, and in Belgrave Square adjacent, but I have not recently observed its occurrence here. Amongst the Privet in some parts of Eaton Square the Tea Tree (*Lycium barbarum*) has been planted, and it flowers, though but sparingly, in London air.

When a boy, I remember I strolled through the north central garden of Eaton Square (let us say about forty years ago), this ground being then cultivated by Tuck the florist, who subsequently took the Sloane Street Nursery. At that time it was replete with choice flowers of the period, now neither this nor the companion gardens make any special display; in fact, their arrangement altogether is chiefly interesting from an historic point of view, as illustrative of a style of gardening that belongs to the first half of this century. One or two of the squares have central beds, which are planted out in the modern manner, but on most of the beds are only straggling representatives of the flowers of September, such species as the Sunflower, "Aaron's Rod," Michaelmas Daisy, Marigolds, Saxifrages, with some Dahlias and China Asters looking in poor condition. Belgrave Square may be said to have the advantage of its neighbour—its one garden from its dimensions allows of a better arrangement, and it would seem the residents bestow more attention upon this than the Eaton Square folks do upon their green domain; also there are fewer trees generally and fewer Ashes in particular. The Elms, placed in pairs at the four entrance gates in 1828, are apparently thriving. Round the greater part of the square within the Privet hedge is another of Lilacs. There are many evergreens, including some fine Aucubas, and in the centre of the ground are shrubberies with flower beds interspersed. One misses the Azalea in this and the other squares, the more because it was formerly much cultivated in the Chelsea nursery gardens.

In the smaller Chester Square garden I observed a fine Black Poplar amongst other trees of the kinds already mentioned, also a Mountain Ash (*Pyrus Aucuparia*) near the railings, a tree not frequent about London, and the austere berries on which I was solicited to pick by a party of juveniles.—J. R. S. C.

THE ENGLISH ARBORICULTURAL SOCIETY.

THE above Society has been formed about twelve months, and is in a very flourishing condition, numbering over 120 members. They have had three excursions, the first to the Forestry Exhibition in Edinburgh last year; the second to Lowther Castle in July last, when they were joined by the Scottish Arboricultural Society at Carlisle, and were entertained in a sumptuous manner by Mr. Watt, of Messrs. Little & Ballantyne, Knowfield Nurseries. The third excursion was to Cragside, through the kindness of Sir Wm. Armstrong, on Friday last. The members were much pleased with the reception given to them by Sir William Armstrong and his Steward Mr. Wm. Bertram.

Cragside has been planted in about twenty years. It was then, as it is named, a bare cragside, but by judicious planting is now, perhaps, not surpassed for sylvan scenery, embracing as it does about 1400 acres planted, 100 of them with Coniferae, ornamental and American plants. The planting of forest and ornamental trees has been at the rate of about 250 acres annually the last three years. One firm alone, Messrs. Wm. Fell & Co., Wentworth Nurseries, Hexham, supplied last year 300,000 Scotch Firs. The members of the Association dined at Rothbury under the presidency of Mr. T. P. Dods, supported by the energetic Secretary, Mr. J. Davidson. Mr. Watt of Messrs. Little & Ballantyne, Carlisle, stated that one gentleman present had given to his ducal employer in twenty-five years £100,000 for timber, averaging 30s. per acre per annum for ground not worth 2s. 6d. per acre, hence the importance of such an association. The Chairman also gave some interesting statistics of timber in America, the decline of it, and that planting has not been done to keep pace with the demand.—B. COWAN.

TRINITY COLLEGE BOTANIC GARDENS, DUBLIN.

I HAVE returned from a holiday run through Munster, Leinster, and Ulster, and amongst the most agreeable memories are those of the few hours I had with Mr. Burbidge, the respected Curator of these Gardens. This gentleman has the happy faculty of making perfect strangers quite "at home," not merely personally, but with the thousands of occupants of beds, borders, and the various houses. He has some anecdote or reminiscence to tell of that venerable shrub or this newly introduced hardy flower, some peculiar property of plants in the medicinal department; or, if you go into the stoves, he at once introduces you to a number of old acquaintances of his from Java and Borneo. I have on previous occasions through your columns detailed at some length a few of the occupants of the large Palm house, including *Arecas*, *Calamus*, *Cocos* (including the beautiful *C. Weddelliana*), *Chamaedorea*, *Thrinax*, *Kentias*, and *Acanthophaea*, &c., with some handsome tropical climbers, Bamboos, Lemon trees, Bread Fruit, and Sago. I also recollect in 1883, about this time, noticing some curious and rare plants in the stoves and Orchid houses, also in the cool and warm fernery, while still more interesting would be the various pits and cool frames. There is a *Sarracenia* and *Nepenthes* pit containing complete collections, and specialists will know what this means. Even more interesting is the peculiar summer method of treating *Todeas* and *Killarney Ferns* adopted by Mr. Burbidge. To all outward appearance the structures resemble a common frame, but the inside is excavated below the level of the surrounding soil and rocks; chasms and miniature waterfalls are made to resemble the native habitat of those shade and moisture-loving Ferns.

In other adjoining cool frames and pits are many varieties, especially among alpine plants; for instance, in the *Primula* group, not now alluding to some curious Alpine *Auriculas*, or the various forms of *Primula Sieboldi*, there was the Bird's-eye Primrose (*P. farinosa*), *P. Clusiana*, *P. denticulata*, *P. obconica*, and *P. scotica*, to which may be added *P. rosea*, *P. spectabilis*, the Sikkim and Abyssinian Primroses. *Polyanthus* and other choice Primroses, that take care of themselves outdoors, had quiet half-shaded nooks and corners here and there beside hedges or walls, as Mr. Burbidge finds nothing injures the better and choicer sorts of this family so much as hot summer sun, which generates red spider and the inevitable canker and swelling of the root stem, more than once alluded to by Mr. Wolly Dod, as having deprived him of some of his favourites in Cheshire. There was there some curious hardy succulents and *Cacti*, which brought us to the long range, divided into several compartments, some for cool Orchids, foliage plants, select Azaleas and Camellias, the rarer and better class of greenhouse plants not often met with elsewhere. An old favourite of fifty years ago, *Fuchsia corymbosa*, with glorious pendent bunches of bloom, forcibly reminded us of this latter fact when leaving this range. *Chrysanthemums*, a complete collection of every introduced variety up to last spring, are well grown, and had a special glass range preparing for their reception to bloom in later on.

Where shall I commence to give your readers an idea, even a faint one, of the wealth of showy, rare, and curious hardy border flowers? Seven special numbers would be insufficient if I were to include the cultural details. Without moving further than the front of this long glass range, we are just in time to see the new *Tigridia conchiflora* and *T. c. alba*, and having for company the little beauty, *Papaver nudicaule*, and *P. n. album*,

too seldom seen. A step further, and we see *Crinums*, *Belladonna Lilies*, rare *Veronicas*, *Eucomis punctata*, *Schizostylis coccinea*, *Pyrethrum serotinum*, *Phlox Nelsoni*, and *P. amoena*; some of the more tender *Mallows*, *Hellebores*, *Anemone pulsatilla*, and many others. To enjoy this garden the visitor should come at four different periods, one at least being the spring, to see the *Narcissi*—one of the largest named collections in Europe being here. Equally pleasing would be the *Lilies*, *Irises*, *Anemones* (a speciality), *Pæonies*, *Hellebores*, *Campanulas*, *Phloxes*, *Columbines*, various *Composites*, *Dianthus*es, *Veronicas*, *Carnations* and *Pinks*, *Thalictrums*, *Linums*, double *Lychnis*, *Stokesia cyanea*, which I can merely name.—W. J. MURPHY, *Clonmel*.

STEPHANOTIS AND GARDENIAS.

In a somewhat remarkable manner Mr. Muir has directed attention to two of the choicest inhabitants of our stoves, though few, I feel sure, will follow his advice and throw them away. Apart from the value which might be set upon them individually, we have only to refer to the advertising columns of the horticultural press to learn that they are still required in quantity, and so it will continue, I venture to predict, till the cut flower trade passes out of fashion. Those that do not appreciate their odour are not compelled to purchase, hence Mr. Muir has acted as most men would do provided the blooms were little valued by their employers, and this is very good reason for your correspondent to discontinue their culture; still it by no means lessens their worth and general usefulness, and while quite agreeing in one particular with Mr. Muir as to the powerful fragrance of the *Gardenia*, it may be observed that many choice flowers are similar, taking for examples early *Ornament* *Hycinths*, *Tuberose*s, *Paper White Narcissus*, in this case even stronger than the *Gardenia*. A grand flower is the old *Double White*, and also the fringed white *Camellia*, but we must have wire to bring them into use—in this case devoid of fragrance, and which so many long for. Many stove plants, like children, require constant attention to keep them clean, and while this may take much time we certainly cannot dispense with our most valuable flowering plants on this account; for if we did, *Bouvardias*, *Gardenias*, *Eucharises*, *Stephanotis*, *Euphorbias*, *Dipladenias*, *Epiphyllums*, *Hoyas*, *Ixoras*, and a host of others would have to be thrown out. With all due respect to the queenly *Lily of the Amazon*, so much valued and admired, any arrangement of it alone must be very formal. It would need some of the "plenty of other flowers, which are just as pretty and sweet," to which your correspondent refers, but which he fails to cite, to make the arrangement pleasing.

That *Stephanotis* and *Gardenias* may be kept clean in a stove I know well, and that they pay to keep clean I am also convinced, and anyone who will persevere in this direction will be well paid; if he neglects them he never will. We have nothing among stove-flowering shrubs to equal the *Gardenia* for floriferousness, and its profuse-flowering qualities are unique. In support of the value of these charming flowers I append the following quotation from the *Walsall Observer* of February last, which, in reviewing the extensive plant-growing establishment at Harefield Grove, says:—"Gardenias for instance fetch good prices, their lovely fragrant flowers being especially in request for wedding bouquets, and command from 12s. to 50s. per dozen blooms, a house 130 feet long and 18 feet wide being devoted to them." We have many valuable *Orchids*, *Lily of the Valley*, *Hyacinths*, and other bulbous plants, *Jasmines* of sorts, and many more; but we cannot afford to "throw" out the *Gardenias* and *Stephanotis* from our stoves unless Mr. Muir can furnish some better guarantee as to what of equal or greater value can fill their places.—E. JENKINS.

INTERNATIONAL POTATO EXHIBITION.

OCTOBER 7TH, 8TH, AND 9TH.

WITH the support of numerous influential friends, an experienced Committee, and an energetic Secretary, the Potato Exhibition at the Crystal Palace has been rendered one of the most important annual events of the autumn season. Liberal prizes in judiciously arranged classes have during several years produced extensive and thoroughly representative displays of the indispensable tuber, which have unquestionably done valuable service in many ways. They have called public attention to the importance of the crop, stimulated the raising of varieties, and given a useful impulse to the trade which only those most concerned can accurately estimate. The promoters and supporters well deserve the repeated successes which have rewarded their efforts.

The Show, which opened on Wednesday and continues to-day (Thursday) and to-morrow, is like its predecessors, satisfactory in most respects. Though as a consequence of the season the tubers generally are not quite so large as usual, they are very even and clean, and in consequence the competition is extremely close.

As the awards were not made until just as we were going to press, we can only give the names of the prizewinners in the principal classes. In all the classes each dish contained nine tubers, and over 1000 dishes were entered in competition, in addition to several collections shown by seed firms.

Twenty-four varieties, fourteen entries.—The first prize, offered by Messrs. J. Carter & Co., was won by Mr. T. Hughes, gardener to Colonel Cartwright, Byfield, Northampton, with the following varieties:—*Adirondack*, *Sutton's*

Early Regent, *Crimson Beauty*, *Schoolmaster*, *Vicar of Laleham*, M.P., *Sutton's Reading Russet*, *Snowdrop*, *Rufus*, *Fidler's Prolific*, *Blanchard*, *Chancellor*, *Queen of the Valley*, *Cosmopolitan*, *Edgcote Purple*, *Sutton's First and Best*, *Beauty of Hebron*, *Edgcote Seedling*, *The Dean*, *Sutton's Favourite*, *Sutton's Prizetaker*, *London Hero*, *Lord Rosebery*, and *Sutton's Woodstock Kidney*. These were beautiful even samples, and amply merited the award, which it may be added was obtained by the same exhibitor last year. Second Mr. W. Ellington, West Row Gardens, Mildenhall, Suffolk. Third Mr. E. S. Wiles, gardener to R. A. Cartwright, Esq., *Edgcote*, Banbury. Fourth Mr. E. Chopping, The Mills, Milton. Fifth Mr. William Kerr, Dargavel, Dumfries. Sixth Mr. G. Allen, gardener to Sir F. Burdett, Bart, Ramsbury Manor. Seventh Mr. J. Lye, Cliffe Hall, Market Lavington.

Twelve varieties, nine entries.—James McIntosh, Esq., Oatlands Park, Weybridge, gave the first prize, which was won by Mr. C. W. Howard, Bridge, Canterbury, with *Duke of Albany*, *Adirondack*, *Magnet*, *The Dean*, *Vermont Champion*, *Reading Russet*, *Chancellor*, *Beauty of Hebron*, *Schoolmaster*, *Vicar of Laleham*, *Ashtop Fluke*, and Mr. Breese. Second, Mr. Tom Tooley, Newlands, Banbury. Third, Mr. T. Gilmour, Hawkharst, Kent. Fourth, Mr. G. Akhurst, gardener to Mrs. Bramah, Davington Priory, Faversham. Fifth, Mr. R. West, gardener to J. R. Wigram, Esq., Northlands Salisbury; and sixth, Mr. Woolford, Little Missenden Abbey, Great Missenden.

Nine varieties, sixteen entries.—All the prizes were given by Mr. C. Fidler, Reading. First, Mr. J. Hughes. Second, Mr. Ellington. Third, Mr. E. S. Wiles. Fourth, Mr. W. Kerr. Fifth, Mr. E. Chopping; and sixth, Mr. R. West.

Six varieties, twenty entries.—The premier prize offered by Messrs. Webb and Sons, Stourbridge, was awarded to Mr. J. Hughes, for handsome tubers of *Reading Russet*, *Snowdrop*, *First and Best*, *London Hero*, *Chancellor*, and *Edgcote Purple*. Second, Mr. S. Rogers, Whittlesea. Third, Mr. W. Ellington. Fourth Mr. E. Chopping; and fifth Mr. P. McKinlay, Anerley.

Three white round varieties, nineteen entries.—First Mr. R. Dean, Ealing, with *Schoolmaster*, *London Hero*, and *Harvester*, beautiful even tubers. Second Mr. J. Hughes. Third Mr. E. Chopping. Fourth Mr. W. Ellington; and fifth Mr. John Hughes.

Three dishes of coloured round varieties, twenty-two entries.—First Mr. L. Stanton, Maidford House, Towcester, with *Vicar of Laleham*, *Reading Russet*, and *Adirondack*. Second Mr. C. W. Howard, Bridge. Third Mr. E. S. Wiles. Fourth Mr. W. Kennard. Fifth Mr. W. Ellington.

Three white kidney varieties, sixteen entries.—First, Mr. E. S. Wiles with *Snowdrop*, *Cosmopolitan*, and *Edgcote Seedling*. Second, Mr. J. Hughes. Third, Mr. W. Ellington. Fourth, Mr. E. Chopping; and fifth, Mr. John Hughes.

Three coloured kidney varieties, fourteen entries.—First, Mr. E. S. Wiles with Mr. Breese's *Sutton's Prizetaker*, and *Edgcote Purple*. Second, Mr. E. Chopping. Third, Mr. J. Hughes. Fourth, Mr. W. Ellington; and fifth, Mr. W. Kerr.

Single dishes.—All these classes were confined to English-raised varieties. Any white round variety.—First, Mr. C. W. Howard with *Schoolmaster*. Second, Mr. R. West. Third, Mr. R. Dean; and fourth, Mr. W. French Harlow. Twenty-two entries. Any coloured round.—First, Mr. C. Stanton with *Vicar of Laleham*. Second, Mr. J. Lye. Third, Mr. C. W. Howard; and fourth, Mr. E. G. Wiles. Twenty-one entries.

Any white kidney variety.—First, Mr. C. W. Howard with *Chancellor*. Second, Mr. J. Hughes. Third, no name; and fourth, Mr. W. Kerr. Twenty-three entries. Any coloured kidney.—First, Mr. J. Hughes with *Cardinal*. Second, Mr. E. S. Wiles. Third, Mr. G. Allen; and fourth, Mr. W. Kerr. Eighteen entries. Any new white variety not offered to the public before 1884.—First, Mr. E. Chopping with *Chancellor*, very handsome. Second, Mr. J. Hughes with *Fidler's Prolific*. Third, Mr. J. Hughes with *Doctor*. Fourth, Mr. W. Ellington with *Chancellor*. Fifteen entries.

Extra classes.—Six varieties, to include *Ashtop Fluke*, *Cosmopolitan*, *Sukreta*. All the prizes were offered by Messrs. J. Carter & Co, High Holborn. First, Mr. J. Lye with *Ashtop Fluke*, *Cosmopolitan*, *The Dean*, *Schoolmaster*, *Sukreta*, and *Reading Russet*. Second, Mr. J. Forder, Hillington Hall.

Four dishes, to include *Fidler's Success* and *Prolific*.—First, Mr. J. Hughes with the varieties named and *First and Best* and M.P. Second, Mr. E. S. Wiles with *Edgcote Purple* and *Reading Russet*, in addition to the others. Third, Mr. W. Ellington. Fourth, Mr. C. Ross, Welford Park, Newbury; and fifth, Mr. W. Woolford. In the classes for seedling Potatoes the awards had not been made when we left the exhibition. The miscellaneous contributions were not quite so numerous as usual, but Messrs. Webb & Sons, J. Carter & Co., Harrison & Sons, and C. Fidler had large collections.

FRUIT SHOW AT THE CRYSTAL PALACE.

OCTOBER 7TH AND 8TH.

APPLES and Pears and other hardy fruits were staged in large quantities at the Crystal Palace on Wednesday. On the eve of going to press we are unable to describe the Exhibition fully, but the fruit was fully up to the average in quality. The following are brief details of the awards; further particulars will be given next week. Upwards of 2000 dishes were shown including about 13,000 fruits, six fruits to each dish.

Class A, for the best exhibition of kitchen and dessert Apples, produced six competitors, who staged in all 733 dishes of six fruits each. The first prize was awarded to Messrs. G. & J. Lane, nurserymen, St. Mary Cray, Kent; the second to Messrs. G. Bunyard & Co., The Old Nurseries, Maidstone; the third to Messrs. Thomas Rivers & Son, nurserymen, Sawbridge-worth; and the fourth to Messrs. Paul & Sons, The Old Nurseries, Cheshunt.

Class AA, twenty-four dishes of Apples for amateurs. Mr. S. Ford, gardener to W. E. Hubbard, Esq., Leonard's Lee, Horsham, staged a splendid collection and took first prize; the second going to Mr. A. Waterman, gardener to H. A. Brassey, Esq., M.P., Preston Hall, Aylesford; and

third to Mr. H. Davis, gardener to H. S. Lake, Esq., Furlawn House Chiswick.

Class B, the best collection of Pears, six fruits each.—Seven collections in competition, and 381 dishes were staged in all. Messrs. Rivers & Son secured the first prize somewhat easily, the second falling to the share of Mr. J. Butler, gardener to N. J. Thomas, Esq., Orchard Lane, Sittingbourne; the third to Messrs. G. Bunyard & Co., and the fourth to Mr. Waterman. Class BB, twelve dishes Pears for amateurs.—This was a good class, the first prize being awarded to Mr. A. Waterman, the second to Mr. Forl, and the third to Mr. C. J. Goldsmith, gardener to C. A. Hoare, Esq., Kelsey Manor, Beckenham, fifteen collections competing. Class CC, twelve dishes of Apples for amateurs. Mr. J. Gilmour, gardener, Hawkhurst, Kent, was placed first; Mr. Dance, gardener to Colonel Lowe, Gosfield Hall, Halstead, Essex, second; and Mr. G. Collins, gardener to F. A. Rose, Esq., Wandsworth Common, third.

VEGETABLES.—For the best collection of vegetables (open) Mr. A. Waterman, who showed fruit very well, was an easy first. He staged a very fine collection, which included many noteworthy examples. Mr. J. Neighbour, Bickley, Kent, was second, also showing very well; Mr. T. A. Beckett, Cole Hatch Farm, Penn, Amersham, was third, and Mr. C. J. Waite fourth. For the best twelve dishes of vegetables from amateurs Mr. C. J. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher, was adjudged the principal prize for an excellent collection. The second prize was won by Mr. T. A. Beckett, and the third by Mr. Waterman. A class was also provided for cottagers, but only two entries were received.

For a collection of Ornamental Gourds Mr. C. Osman, Southern Metropolitan District School, Sutton, was awarded first prize for a large and complete group, including about thirty sorts. Mr. G. Sturgess, gardener to Dr. E. Freshfield, Chipstead, was second; and Mr. Jas. Sharpe, gardener to F. Hatchett, Esq., Parkfield, Grove Park, Lee, third. Mr. C. Osman was again well to the fore in the class for Pumpkins and Gourds, Mr. Sturgess being second, and Mr. Sharpe third. The last named exhibitor sent the largest Pumpkin, a monstrous specimen, weighing 108 lbs., securing him the first prize; Mr. Osman was second with one weighing 67 lbs.; and Mr. Sturgess third, with a fruit 48 lbs. in weight.

MISCELLANEOUS.—In the miscellaneous classes some notable exhibits were admired. Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, Sussex, sent a large and very fine collection of Apples and Pears, 120 dishes of the former, and thirty dishes of the latter being staged. Messrs. William Paul & Son, Waltham Cross, Herts, also sent a splendid collection, comprising upwards of 200 dishes; Messrs. James Veitch & Sons, Royal Exotic Nursery, Chelsea, London, S.W., were represented by a collection of more than 200 dishes, most of the fruit being of good quality. Mr. J. Butler showed a fine collection of Pears.

Amongst vegetables were a fine stand of Onions, including twenty-eight varieties, from Mr. H. Deverill, Royal Bulb and Seed Stores, Banbury. Mr. C. Osman showed a good collection of different vegetables, and a large group of tuberous Begonias from Messrs. John Laing & Co., Forest Hill, was much admired.

First-class certificates were awarded for the following Apples:—

Apple Prince Bismarck (J. Veitch & Sons).—A large culinary Apple, 3 to 3½ inches deep, globular in form, with a deep eye, of a white or greenish semi-transparent colour, with a few crimson streaks especially round the stalk. Very handsome and distinct.

Apple September Beauty (Laxton).—A dessert variety, of medium size, richly streaked with crimson. Showy and of good quality.

HARDY FRUIT GARDEN.

FOR our selections of fruit to be as useful as possible we must give the first place to twenty-four sorts of dessert Apples and twenty-four culinary Apples, selected the greatest number of times in a poll taken for the whole of Great Britain at the Apple Congress last year, naming them in the order given in the published lists by Mr. Barron under the auspices of the Fruit Committee of the Royal Horticultural Society.

DESSERT APPLES.—King of Pippins, Cox's Orange Pippin, Ribston Pippin, Kerry Pippin, Blenheim Pippin, Irish Peach, Devonshire Quarrenden, Sturmer Pippin, Scarlet Nonpareil, Court Pendu Plat, Yellow Ingestrie, Fearn's Pippin, Claygate Pearmain, Worcester Pearmain, Margil, Wyken Pippin, Cockle Pippin, Court of Wick, Red Astrachan, Adams' Pearmain, Mr. Gladstone, Golden Pippin, Mannington's Pearmain, Gravenstein.

CULINARY APPLES.—Lord Suffield, Dumelow's Seedling, Keswick Codlin, Warner's King, Blenheim Orange, New or Winter Hawthornden, Cellini, Ecklinville Seedling, Stirling Castle, Hawthornden, Manks Codlin, Golden Noble, Cox's Pomona, Alfriston, Emperor Alexander, Northern Greening, Tower of Glamis, Mère de Ménage, Beauty of Kent, Lord Derby, Yorkshire Greening, Annie Elizabeth, Norfolk Beefing, Loddington Seedling.

The foregoing selections cannot fail to be very useful for private gardens. If, however, we had to plant trees by the hundred for a market garden we should confine our planting to a few sure-fruited sorts, such as of dessert sorts: Kerry Pippin, King of Pippins, Cox's Orange Pippin, Margil, Fearn's Pippin, and Court Pendu Plat; and of culinary sorts:

Keswick Codlin, Duchess of Oldenburgh, Warner's King, Golden Noble, Blenheim Pippin, and Gooseberry.

PEARS.—Summer Doyenné, Citron des Carmes, Beurré Giffard Jargonelle, Fondante de Cuerné, Desiré Cornélie, Souvenir du Congrès Summer Crasanne, Williams' Bon Chrétien, Colmar d'Été, Fondante d'Automne, Doctor Hogg Bergamot, Duchesse d'Orléans, Comte de Lamy, Madame Treyve, Summer Beurré d'Arcenberg, Robert Hogg, Fondante de Charneau, Marie Louise, Marie Louise d'Uccle, Doyenné du Comice Knight's Monarch, Seckle, Urbaniste, Maréchal de Cour, General, Todleben, Dana's Hovey, Comte de Flandre, Hampson's Forelle, Josephine de Malines, Jewess, Basi vaet, Winter Nelis, Beurré Superfin, Huyshe's Victoria, Glou Morceau, Easter Beurré, Elizé d'Heyst, Olivier des Serres, March Bergamot, Madamo Millet.

PEARS FOR A MARKET GARDEN.—Summer Doyenné, Lammas, Windsor, Caillot Rosat, Bellissime d'Automne, Williams' Bon Chrétien, Yat, Autumn Bergamot, Hesse, Marie Louise, Beurré Clairgeau, Eyewood, Louise Bonne of Jersey, Comte de Flandre, Beurré Bos, Beurré de Capiaumont, Rondelet, Catillac, Bishop's Thumb, Broompark, Fertility, Winter Nelis.

TWELVE PEARS FOR A SMALL GARDEN.—Williams' Bon Chrétien, Fondante d'Automne, Comte de Lamy, Doyenné du Comice, Knight's Monarch, Dana's Hovey, Comte de Flandre, Jewess, Glou Morceau, Winter Nelis, Easter Beurré, March Bergamot.

COOKING PLUMS.—Early Rivers, Diamond, Early Orleans, Victoria, Lafayette, Prince Englebert, Prince of Wales, Automne Compôte, Belle de Septembre, Grand Duke, Cluster Damson.

DESSERT PLUMS.—Green Gage, Purple Gage, McLaughlin's Gage, Transparent Gage, Reine Claude de Bavay, Washington, Bryanston Gage, Denniston's Superb, Jefferson, Coe's Golden Drop, Kirk's Blue Impératrice.

SELECT PLUMS FOR A SMALL GARDEN.—Green Gage, McLaughlin's Gage, Transparent Gage, Reine Claude de Bavay, Coe's Golden Drop, Blue Impératrice, Early Rivers, Victoria, Diamond, Early Orleans, Belle de Septembre, Cluster Damson.

PLUMS FOR A MARKET GARDEN.—Early Rivers, Diamond, The Czar, Blue Prolific, Perdrigon, Violet Hâtive, Early Orleans, Corte's Nota Bene, Dauphine, Belgian Purple, Grand Duke, Washington, Prince of Wales, Victoria, Prince Englebert, Pond's Seedling, Coe's Golden Drop, Belle de Septembre, Prune, and Cluster Damsons.

CHERRIES.—Early Purple Gean, Early Rivers, Belle d'Orléans, Empress Eugénie, May Duke, Black Tartarian, Governor Wood, Archduke, Reine Hortense, Transparent, Bohemian, Black Bigarreau, Bigarreau, Belle Magnifique, Elton, Late Duke, Morello.

Select Cherries for a Small Garden.—Early Purple Gean, May Duke, Bigarreau, Governor Wood, Belle Magnifique, Morello.

Cherries for a Market Garden.—Early Purple Gean, Early Rivers, Adam's Crown Heart, Elton, White Heart, Black Heart, Waterloo, May Duke, Black Eagle, Flemish, Kentish, Bigarreau.

PEACHES.—Alexander, Early Beatrice, Early Albert, Rivers' Early York, Dr. Hogg, Grosse Mignonne, Royal George, Noblesse, Belle Bauce, Barrington, Walburton Admirable.

NECTARINES.—Advance, Lord Napier, Stanwick Elruge, Downton, Rivers' White, Pitmaston Orange, Balgovan, Pine Apple.

Figs.—Brown Turkey, Brunswick. Apricots.—Kaisha, Large Early, Moorpark, Peach, Orange. Medlars.—Dutch, Nottingham. Nuts.—Cosford, Pearson's Prolific, Cob, Red Filbert, Duke of Edinburgh. Raspberries.—Prince of Wales, Carter's Prolific, Yellow Antwerp, Belle de Fontenay.

GOOSEBERRIES.—Early Sulphur, Green Gage, Red Warrington, Red Champagne, Yellow Champagne, Ironmonger, Keen's Seedling, Pitmaston Green Gage, Roaring Lion, Crown Boh, Green Walnut. Currants.—Red Dutch, Victoria, White Dutch, Lee's Prolific Dutch.

FOR MARKET GARDEN.—Gooseberries.—Whitesmith, Early Sulphur, Velvet White, Crown Bob, Warrington, Lancashire Lad, Red Rifleman, Golden Drop, Monarch. Currants.—Red Scotch, Red Dutch, Baby Castle, Black Naples, Baldwin's Black, Lee's Prolific Black. Raspberries.—Carter's Prolific, Prince of Wales, Fastolf, Red Antwerp, Belle de Fontenay.

FRUIT FORCING.

VINES.—*Early Houses*.—An examination of the inside borders of houses intended for starting next month should be made at once, and in case they have become very dry a supply of water at a temperature of 85° to 90° will be necessary, as every particle of the soil should be properly moistened before the Vines are started. If the Vines are weak from carrying heavy crops or a long course of early forcing, tepid liquid manure may be employed. Until the time arrives for closing the house ventilate freely.

Early Vines in Pots.—Examine these as they are placed in position for forcing. Top-dress with rich compost, enlarging the holes at the bottom and sides of the pot to allow of the roots finding their way into the plunging material, which is a consideration in crop and quality, also to allow the water, of which they require copious supplies, to pass away freely. Remove young Vines intended for cutting back or planting in the spring to a cool house or west wall, where they can be made secure from injury by wind, protecting pots with spent tan or litter.

Ripe Grapes.—From now until the Vines are clear of foliage will be found the most trying period in the year for keeping Grapes. Black

Hamburgs intended for use through November, and previously divested of all laterals, may be cut back to within two eyes of the hunch, and shoots from which the Grapes have been cut may also be shortened where the wood is crowded. If the inside borders are damp a covering of dry fern or dry straw will absorb much moisture, and gentle fires will be necessary. Examine the hunches twice a week, removing decayed berries, and the house must be cleared of plants, the glass being kept clear of all accumulations likely to cause damp.

Renovating Borders.—The renovation of all midseason borders have been, or ought without further delay to be, brought to a close, and late houses in which the Grapes do not finish well must be attended to. If the Vines have the run of outside as well as inside borders, one or other may be taken out and remade at any time after the Grapes are ripe without detriment to the present or the succeeding crop of Grapes. Dry mild weather is the best for operations of this kind, as the roots are less liable to be injured, and the compost does not become close. Well-drained borders of moderate width, and about 30 inches depth, are best adapted for Vine culture, especially in low situations, as they are least costly, warmer, and take more stimulating food with impunity than large masses of rich matter over which the cultivator has much less control. When the borders are well made and only require keeping up to the mark by the annual top-dressing, all old mulching may be removed down to the roots, substituting good compost, consisting of rough turfy loam, crushed bones, and charred refuse. When the foliage is changing colour place old lights or shutters over the outside borders, with a sharp pitch to the front for throwing off water, but they ought not to be closed at the ends, as a free circulation of air will be needed until the time arrives for cutting and removing the fruit to the Grape room, when the lights may be taken off, a good layer of litter being sufficient for keeping out severe frosts.

PLANT HOUSES.

Shading.—Plants must now have full exposure to sunshine, the blinds being thoroughly dried and stored away for the winter. It is always a good plan to prepare plants for this change by exposing them gradually to more for a few weeks before shading is entirely dispensed with, and then no check or injury to the plants will result. Ferns will bear all the sun we are likely to get after this date if they have been exposed to plenty of light during the growing season; but if they have been heavily shaded their fronds will be weak and tender, and must still be shaded for a few weeks. Phalænopses that have been heavily shaded must now be exposed to as much light as possible, but this must be done gradually, using the blinds only for a few hours during bright sunshine until they will bear full exposure. It is necessary to harden and prepare them as much as possible for the winter, or they will not remain in a healthy condition during that trying season. The blinds will be needed on the south side of the Odontoglossum house for some weeks yet.

Cleaning Houses.—Clean all houses in which plants are to be stored for the winter, thoroughly washing the glass and woodwork with hot water and softsoap, limewash the walls, and renew the moisture-holding material upon which the pots stand. Every portion of the houses should be made perfectly clean and sweet. Clean the paths and curbs if formed of stone by using a little chloride of lime; this is a much quicker process of cleaning stonework than by means of scrubbing, and will in a few minutes leave the stone as clean as when new. The glass outside must also be thoroughly washed. It is a great mistake to leave this work until frost compels the plants to be taken under cover. Our plan is to house all plants first from cold and other frames that require a certain amount of rest during the autumn and winter, and then utilise their places for hardier plants until the houses in which they are to be stored are prepared for them.

Azaleas.—Where these have been standing outside to ripen their wood lose no time in getting them under cover. If they remain outside much longer they are very liable to become saturated at their roots by heavy rains. When the plants stand outside until the soil is saturated they generally throw off a very large per-centage of their leaves after they are housed. As the work of housing proceeds, carefully examine them, and if any trace of thrips can be found, the plants must be well syringed with a solution of tobacco water in which about 1 oz. of softsoap has been dissolved to each gallon of the mixture. If this precaution is taken to examine and thoroughly clean any infested plants, they will give no further trouble during the whole of the winter.

Heaths and Epacris.—Remove these at once into cold frames until the house is cleaned which they are to occupy for the winter. Erica gracilis and hyemalis often turn blind and fail to open their flowers through being left outside until the soil about their roots becomes saturated. This can be prevented by placing them in cold frames, so that they can be protected from heavy rains. Ventilate the frames freely all night when mild, and remove the lights during the day in fine weather. Epacris require the same treatment. Black fly has been very abundant this season, and upon examining our plants we found a quantity established on the upper portion of the shoots. This is the first time we have observed these plants attacked by aphides. The plants have been dipped in a solution of tobacco water and the insects destroyed. Any plants that may have been similarly affected must be carefully examined again when they are housed, for if any insects remain upon them they will spread and probably do much injury when the plants are introduced into heat to force them into flower. These plants must be watered with great care, or else the fine silk-like roots soon perish. Very frequently they are kept too dry after they are housed, and no treatment will sooner prove fatal to the plants. On no account allow them to suffer by an insufficient supply of water.

THE BEE-KEEPER.

USEFUL HINTS ON BEE-KEEPING.

THE honey season for 1885 is now closed. On the whole it has been a productive one, although the low temperature in the north of Scotland has been disastrous to many hives. In fact, considering the many cold days and want of sunshine, with frosty nights every month, it is surprising where the bees could gather so much honey as they have done this year. Where they have been well managed, large takes have been realised, 150 lbs. having been had from some hives, and, as nearly as I can judge, half a hundredweight will be the average yield from each hive, leaving plenty inside to tide the bees over till next May.

The loss of queens through swarming or having been deposed, owing to the nature of the year taxing the queen in a manner similar to that of stimulative feeding, has been great. Bees were swarming so late as the middle of September, and so far as I have observed, thirty per cent. have done so, or have deposed their queen. To keep such hives will but disappoint their owner when spring comes. Now is the time to put matters right. An experienced bee-keeper can easily tell by the movements of the bees and the molestation they get from stranger bees whether a hive is queenless or not. Where young queens have been joined lately there need be little uneasiness; but, to be sure all is right, feed a little for a few days, until the bees are induced to rear the young. When they are observed carrying pollen freely, it may be taken that all is right, and will do for straw hives where a small patch of sealed brood may not be so easily seen as in frame hives. When these are inspected, make sure that the brood is worker, drone seals being raised considerably and convex, while that of the worker is flattish.

Queens to supply the defect may be had at the present time, either from importers or bee-keepers who have spared the lives of some deposed ones. I have several standing on the mantelpiece in a match-box for nearly a fortnight, lively as crickets.—A LANARKSHIRE BEE-KEEPER.

BEE-KEEPING IN MEXICO—PRODUCTION OF WAX.

I AM a resident of Mexico, and derive much pleasure and instruction reading there your valuable paper. I now beg you to answer in your columns the following query.

By what means, entirely regardless of trouble or expense, can the production of wax be artificially increased in a country possessing a very mild, even, and fine temperate climate, with plenty of flowers nine months in the year? Wax in Mexico has a very large demand, and sells readily when bleached at 4s. per lb. and sometimes higher; and although honey sells also well (1s. per lb.) the demand is limited, and on a large production the price is sure to decline very considerably. Bees do exceedingly well there, even with the most primitive systems, which are the only ones used, but the problem is to produce the greatest possible quantity of wax at the expense of everything else.

I enclose circular on "emigration" to my land, offering more liberal terms and greater solid inducements than have ever been presented to emigrants before by any other country of the world. In the depressed condition of all agricultural business in England, as well as in the United States, Canada, Australia, and all other countries where emigrants have been going before, it is quite interesting and very important to those who are looking for a solution to their present difficulties to know that such splendid opportunities are offered to them. By saying a few words on this matter you will surely do an immense good to the farming community and others.—OMEGA.

[Bee husbandry for the production of wax should be conducted much on the same lines as for obtaining honey. Without the latter there cannot be the former. But there are some points which should be kept constantly in view—viz., young queens in plenty, very large frame hives, and strong swarms. It will be advisable to join a young fertilised queen every three months, and to accelerate her introduction

we would cage her some days before the deposition of the reigning one. Raising plenty of queens in so fine a climate will be very easy, but they should be reared from a tolerable strong stock, and divided into nuclei just before hatching. The Cyprian and Syrian races are capital wax-workers as well as producers. To produce the most wax the hive should be 3 feet high, and having eight or nine frames with intermediate bars not more than 9 inches apart; less by 2 inches might be preferable, because large slabs of comb are liable to collapse during warm weather. A number of the hives might be kept for breeding purposes to strengthen the main stocks. Every effort should be used to have strong stocks and plenty of them, and when near the end of the nine months' honey season an entire renewal of queens should be made. Although a frame hive has been advised as being a good one for raising queens, the Stewarton type of hive will be found to answer the purpose well. Block and tackle mounted on a frame will be required for enlarging and handling these hives, because the top ones should be those removed, and often must be enlarged from beneath to keep up the breeding. As the honey is taken it should be immediately fed back (or when the bees will take it, and the weather is favourable not to interrupt outside gathering). This system of feeding back honey to produce wax should be rigidly carried out towards the close of the outdoor gathering. Having plenty of bees at the end of the season to work wax from the honey gathered throughout the year will be a means to that end, though it may not be the solution of the problem.

The centrifugal extractor should not be used, or if so, as seldom as possible. The Lanarkshire Presser (35s.) is a capital machine for expressing all honey, about 5 per cent. only being left, leaving the wax in firmly compressed cylindrical cakes ready for extracting the wax in its pure state, either by solar heat or by steam extractor. The divisional hive has been recommended because the honeycombs which have the most wax can be removed and pressed without touching the brood, which should be left intact. Feed back the honey at every opportunity, and continue the pressing when sealed is the best way of reducing the honey to wax. The extracted wax from the pure comb will require little or no bleaching.

"The best hive in creation," for all purposes and climates, and particularly for wax-raising, will be described in an early number of this Journal.]

NOTES ON BEES.

"CAMBRIDGESHIRE BEE-KEEPER," I am afraid, lacks the necessary experience to criticise our Lanarkshire friend. My advice to him is, "Gain more experience in the bee-keeping art that it may make him a sadder and wiser man. I have gained much information from your correspondent, 'Lanarkshire Bee-keeper,' and have proved his teaching to be sound. When I first started bee-farming I had a half-starved swarm given me that I might try to keep alive for the winter. Soon after an old stock was given me for the diving, which I accomplished almost to the last bee. These I united with the swarm. I had several mishaps from first to last, especially in the feeding. On one occasion I gave the bees syrup in a cracked jar, and thus I lost hundreds of bees. This occurred while I was a reader of the *British Bee Journal*. Soon after I commenced reading the correspondence in the *Journal of Horticulture* on bee-keeping, and I there found the first hint on perforated zinc flooring, and made a hive myself with a perforated floor. I have had another mishap with the syrup since, but thanks to the perforated zinc the bees had a better chance of recovering than before. Perforated zinc, however, is not only useful in mishaps with syrup, but it lets the *débris* through, and withdrawing a slide is a very simple expedient for keeping a clean hive without the expense of surplus floorboards, drying, and the trouble of removing them.

My first hive was a tea-box, which cost a shilling, with a moveable box for the body hive manufactured by myself on the principle of the instructions found in the third number of "Amateur Work," with the difference that I made a moveable box instead of fixed sides. I gave my stock plenty of room in April, and supers (2 lbs. each) with narrow bottom bars in June, but it did not do very well, possibly from the fact that I was too fond of examining and manipulating them. I am afraid that if I had booked all my time in attending them I should show a very heavy deficit in my cash account. In June of this year I bought a swarm which issued from a straw skep, and set it to work on ten frames of foundation; and having fed them (slow feeding) for a few days I put on 2-lb. sections, and it was from this swarm that I got the greatest profit. I have now the old stock fed with over 30 lbs. of 2½d. loaf sugar, the swarm as a stock, and another stock composed of two driven ones. The old stock I have put into a body box 6½ inches deep from the top to the perforated zinc floor with ten frames of foundation, and although the frames are shallow I have added a bottom bar, and I purpose to make another body box the same depth filled with frames and to put it underneath the one they are now in about April next. I say underneath, because I shall make it without angled tin for slides, having the angled tin and slides on the box they are now in, and then on the top of these two boxes I shall put supers wrought by the manufacturer recommended by "A Lanarkshire Bee-keeper," provided the latter will purchase them

at a fair price. After the removal of the supers I shall extract the honey in the top box and remove the same, leaving the bees one box to winter in, as at present supers and 2-lb. sections will not sell here; in fact, people want something less than even pound sections.

Your correspondent, "Hallamshire," seems to think that stocks in skeps and swarms in bar-frames are best. Will your correspondent tell us what he does with stocks in the skeps after swarming, and also with the swarms in the bar-frames after the honey harvest? Any information in these matters will be pleasant reading for the long nights of winter.

I find it difficult to keep my smoker going when manipulating; in fact, as soon as it is set down it goes dead. I can remember when I was a boy that I dipped brown porous paper in a saltpetre solution for the purpose of forming a fuse to ignite fireworks at the end of a kite tail when in the air. Would paper thus dipped do any harm to the bees?

I find the specimen supers of "Lanarkshire" with the glass give the end view to the combs. I think it would be preferable if they could be made to give a side view of the outside comb. Can any of your readers give hints on preventing wasps entering hives besides contracting entrances?—BASIL.

THE HONEY MARKET.

The numerous complaints constantly reiterated on all sides by bee-keepers who have honey to dispose of in either large or small quantities, are a sign that in the near future, if the time has not already come, the price of honey will be so low that the question of production will engage the thoughts of all having an interest in the industry. It is no use disguising the fact that comb honey in large supers is an absolutely unmarketable article; at any rate it is so in the city where I dispose of my surplus, and also in other towns where I have endeavoured to sell large amounts of comb honey at any price whatever. True, the Honey Company offered me for a large glass, some 40 lbs., the magnificent sum of 6d. a pound, nett weight, and also stipulated that I was to take all risk of damages and pay carriage, thus reducing the price to about 5d. a pound. I may be told that it is easy to sell such honey when it has been run from the comb at an extra price on account of its purity and freedom from taint of brood or other contaminating influences. My objection to this is that the trouble of running is not inconsiderable, then the wax has to be rendered down, there is also a great loss of weight, and after all so little do many of the grocers and Italian warehousemen with whom I have to deal appreciate the difference between the purest of honey and the inferior article, that they will only give the same price for honey run from supers as they offer for honey run from the comb, which have been used for brood and other purposes, which depreciate the flavour of the honey afterwards stored in them.

If small supers could be sold at a reasonable price there would not be so much ground for complaint; but this season I have had supers of glass, and wood and glass combined, of weights so varied as 6 lbs., 10 lbs., 12 lbs., 20 lbs., and 40 lbs., and have not been able to dispose of one, but have been compelled to run the whole, and bottle in 1 lb. jars. The sale of 1 lb. sections is to some extent more satisfactory, the prices they have realised this year being 1s. 2d. and 1s. 3d. per section, in quantities of two dozen and upwards. Run honey also in large quantities can be sold neatly labelled and in good clean glass jars at 1s. to 1s. 2d. per bottle, according to the quantity sold, but the majority of bee-keepers have had to sell at prices very much below this, although some have, on the other hand, obtained 1s. 6d. per lb. for their samples sold to the neighbouring residents in small quantities.

That there has been a great amount of honey produced during last year and this I am willing to allow, but it lends very small support to the statement often heard, that in a bad season honey will rise again to its old value, and there is this additional drawback that the constant importation of foreign honey will absolutely prevent there ever being so great a scarcity in England as to have the effect of sending up the price to a sum large enough in a bad season to pay better than a smaller price in an exceptionally good year. It is not well to jump to conclusions, and it is satisfactory to see that in Scotland supers meet with ready sale provided they are of convenient size; but notwithstanding, judging from what can be seen and what can be heard from those who deal in honey and sell it retail in large towns, the days of comb honey are fast giving place to a time when run honey only will be acceptable to the consumer, and it is the wants of the consumer that the apianian is bound to consider. If, then, this is the case, some other plan of obtaining honey must be advertised to than supers. For these reasons supers are expensive and are troublesome, less honey is stored in a super than in an enlargement given below, and more care and attention is required in the production of fine quality honey in supers than the difference in price between the finest and the more inferior qualities seems to warrant. These are suggestions only—thoughts thrown out to thinkers—that from these thoughts practical results may be evolved by the numerous talented apianians who are constantly endeavouring to scheme some plan to meet the ever-changing requirements of the most fickle of consumers—the honey-eater.—FELIX.

TRADE CATALOGUES RECEIVED.

Messrs. Morle & Co., 102, Fenchurch Street, London.—*Catalogue of Dutch Bulbs.*

Ketten Frères, Luxembourg.—*Catalogue of Roses.*

Richard Smith & Co., Worcester.—*Catalogues of Trees, Shrubs, Roses Bulbs, Alpine Plants, &c.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Books (R. G.).—The writer to whom you refer has not prepared a work on the subject alluded to, and we do not think he has any immediate intention of doing so. If he writes such a work you are almost certain to hear about it. (*Young Inquirer*).—The most useful book for you would be Mr. F. W. Bnrhidge's "Cultivated Plants; their Propagation and Improvement," published by Blackwood; but if you desire more scientific instruction on hybridising procure Darwin's "Animals and Plants under Domestication," "The Effects of Cross and Self-Fertilisation in the Vegetable Kingdom," and the "Various Contrivances by which Orchids are Fertilised by Insects," all these being published by Murray.

Dahlias (R., Romford).—The return is too late, as the results have been published in this Journal of October 1st, page 290.

Goddard's Clips for Glass (Inquirer).—Mr. Goddard informs us that as soon as he has made satisfactory arrangements for supplying these useful clips in quantity, he will communicate with us on the subject.

Vines on "the Standard Principle" (T. R. B.).—A more definite explanation of your requirements must be given before we can furnish a suitable reply.

Apples Specked (T. G.).—As the tree is in good condition the specks on some of the fruit may have been caused by hail when the fruit was tender, or by water resting on it and exposed to hot sun. We have often known the fruits on one side of a tree seriously injured by hail, while those on the other, or where sheltered, were perfectly clear.

Climbers, Fruit Trees, and Roses (Constant Reader).—Your letter is such that we cannot answer it satisfactorily to ourselves or usefully to you without further information. Be good enough to say the number of climbers you require, or the length of the walls of the different aspects you desire to cover; also please state whether you desire six Plums as standards and six more as pyramids, or for walls, or only six altogether; also whether you require six Pears for a north wall and the same number for other purposes. If you will make your wants clear and write us as early as possible we shall be able to answer your letter in our next issue.

Clarifying Cider and Perry (W. H. G.).—We know of no modern work on the manufacture of cider and perry, but if all you wish to know is the process of clarifying the liquor you can do so as follows:—To clarify a hogshead take the whites of eight eggs and beat them up in a quart of the liquor, pour this into the cask, and then stir the whole so as to mix them thoroughly. Let it stand for a fortnight or three weeks, and the liquor ought then to be bright.

Plum not Bearing (H. T.).—As your Green Gage trees are in first-rate trim, not too luxuriant, having been root-pruned, and have good bearing spurs, blossoming abundantly, but the incipient fruits drop, all you can do is to protect the trees with nets or blinds from frost and cold winds in the spring. As the trees are on a wall you can do this. The blossom of this variety is more tender than the Victoria, which is one of the most useful Plums that can be grown in cold districts. If you cannot secure a crop with protection we should occupy the whole space with the Victoria, which bears so well on the same wall.

Muscatel Grapes (A. G. F.).—We scarcely know to which Grapes you refer, as Muscatel Grapes are termed Muscatels by some persons, and one of the names of the Muscat of Alexandria is Moscatel Gordo Blanco. The common Muscatel is the White Frontignan, a rather small Grape with cylindrical bunches and richly flavoured berries. The temperature suitable for the Black Hamburgh is also suitable for this variety, but the true Muscatel Grapes only ripen in a Hamburgh house when the Vines are started early in the season and a good temperature is maintained, which even the Black Hamburgh does not object to, though it will succeed very well under what is termed "cool treatment." One of the most useful white Grapes for growing with the Black Hamburgh is Foster's Seedling.

Size of Boiler (W. K.).—Very much depends on the setting and stoking of a boiler as to the length of piping it will heat. As a rule every square foot of effective heating surface in a boiler may be estimated to heat 40 to 50 feet of 4-inch pipe. A saddle boiler 2 feet 6 inches long will answer your purpose. Flued saddles with terminal ends are more powerful than the common kind, but necessarily more costly. In fixing a boiler consideration should be given to the possibility of other houses being erected at a future time, and more piping required to be attached to the existing boiler for heating them.

Apples for Exhibition and Use (Inquirer).—You do not say whether you wish the kinds for exhibition at one time or different times, but we presume they will be required at different times. Dessert Apples: Irish Peach, Worcester Pearmain, Cox's Orange Pippin, Blenheim Pippin, Claygate Pearmain, and Court Pendu Plat. Kitchen Apples:—Lord Suffield, Peasegood's Nonsuch, Bramley's Seedling, Warner's King, Tower of Glamis, and Lewis's Incomparable. These are first-rate Apples, and given somewhat in the order of their ripening. Another dozen are: Dessert.—Kerry Pippin, King of the Pippins, Ribston Pippin, Margil, Boston Russet, and Duke of

Devonshire. Kitchen.—Emperor Alexander, Stirling Castle, Becklinville Seedling, Grenadier, Dumelow's Seedling, and Galloway Pippin. The ground ought to suit Apples.

Peaches and Nectarines for Unheated House (Idem).—We apprehend you require the fruit to ripen successionally, one kind succeeding the other. Peaches.—Alexander, Hale's Early, Royal George, Belle Beauce, Bellegarde, Barrington, and Walhurton Admirable. Nectarines.—Lord Napier, Stanwick Elruge, and Pine Apple.

Phyllocactus Unhealthy (A Constant Reader).—In the absence of any particulars as to the conditions under which the plant is growing, we cannot determine what has caused the blistering on the stems. It certainly is not due to any parasite, but seems to have been caused by some injurious substance dropping upon the surface. The plant is also in an unhealthy condition, and the shrinking of the tissue may be due to an incipient decay. We should advise repotting the plant after removing the worst of the stems. You will find cultural particulars in "Cactaceous Plants," published at this office, post free 1s. 1d.

Culture of the Pomegranate (W. S. P.).—The Pomegranate is usually grown out of doors in the south of England, but the plants are trained to walls with a warm aspect. They are also grown in pots or tubs in conservatories, and only require protection from frost. A light soil, not too rich, is needed, and by shortening the shoots after flowering, and encouraging a free growth, which must be afterwards well ripened, you will find little difficulty with the plant.

The "American Flea" on Chrysanthemums (Subscriber).—Your plants are attacked with the aphid that has received the above name amongst Chrysanthemum growers. It is the same as was alluded to on page 306 last week, where you will observe it was destroyed with soft soap and tobacco water. Another remedy is there suggested to prevent the increase of this destructive pest. All leaves such as the one you have sent should be picked off and burned, as exhausted and discoloured foliage is of no benefit to the plants, only perfectly healthy green leaves assimilating food and storing it in the stems for the support of the blooms. You ought to have watched your plants closely and applied a remedy before the insects took such firm possession of the plants. Remove all insect-infected discoloured leaves at once, and syringe your plants well with the decoctions suggested on the page quoted.

Kiln Dust for Fruit Trees (Laukhill).—It is used extensively, and with the best results in the form of a top-dressing to fruit trees in pots at Sawbridgeworth. About one-third of the dust is mixed with twice that quantity of partially dried horse-dung, and the mixture is moistened with strong liquid manure and applied to the surface of the soil. Equal parts of kiln dust, horse droppings or decayed manure, and good loam, make an excellent top-dressing for all kinds of fruit trees that require assistance in the summer.

Gathering Fruit (C. D.).—Fruit should be gathered when it parts from the trees readily on being raised by the hand. When it cannot be separated from the trees without twisting and breaking the stalks it is not ready, still all should be gathered before the occurrence of severe frost, a slight frost not being injurious. When fruit is much attacked with flies and wasps it is usually ready for gathering. Your fruits already gathered that are losing their crispness may have been stored too soon, but early varieties naturally do this. We do not use hay as a bed for fruit, as it does not improve the flavour of either Apples or Pears, and if the hay is old or "fusty" it quite spoils the quality of fruit. We prefer perfectly clean boards for fruit, handling and arranging it so carefully that it is not bruised in the slightest. Clean, new, perfectly sweet and dry straw is better than hay for storing fruit. After the fruit is dry only a gentle circulation of air is needed, and it keeps better in a rather dark place than a very light one, much dry air and light inciting evaporation and consequently shrivelling.

Extirpating Moles (W. G., Midlothian).—The first plan is to trap them, which only requires some experience and judgment. We were for a long time pestered with them on a lawn, and could not catch them simply because the traps were set in the shallow instead of the deep and consequently main runs. We should ascertain the route the moles take in coming into the gravel pit, or find out the main runs, and making a place proper for a trap put in some soil fully as deep as the run and make it rather firm. If it be a main run or one much frequented by the moles they will burrow through the fresh soil, and you may then introduce the trap with a certainty of a catch. If you proceed in stopping up the runs until you find the moles and set the traps in those we think you will soon clear them. If you place Elder leaves or young wood in their runs they will desert them, and tar and petroleum have the same effect, but the only sure plan of riddance is to destroy them.

Retarding Chrysanthemums (Cambridge).—If the colour is only just visible it does not follow that the blooms will be over before the date named, but everything depends on the weather. The best of growers annually lose some of their finest blooms during a warm bright autumn. Keep your plants in the coolest place possible, on the north side of a wall if you have one, sheltering them with canvas or mats (not touching the buds but supported above them) on cold nights. If a glass wall coping could be fixed it would be very suitable, but the plants must not remain out to be injured by severe frost. When the blooms are half expanded the plants may be placed in any cool shed. The light blooms will be improved rather than otherwise by the absence of light, and it is better to sacrifice a little of the colour of the dark ones than to lose the blooms altogether, especially as it often happens that the too early flowers are exceptionally fine. When the blooms are nearly expanded the plants may be kept almost in the dark for a fortnight. A cool house on a north aspect is sometimes more valuable for retarding early blooms than a heated structure is for accelerating the late ones, but the grower who has both those conveniences is to be envied by those who do not possess them.

Pruning Roses (Pen and Ink).—We should not prune either the standard or dwarf Roses now, except so far as to thin out any weakly growths that may be crowding the trees, and shorten any strong shoots that may have extended far beyond the others, and are unduly drawing the sap from them, the shortening to be done to the level of the other shoots. March is quite soon enough for pruning, and numbers of Roses are not pruned till quite the end of that month or early in April. If pruned early the young growths

succeeding are often cut by frost, but by deferring the work, though the top buds may start and be killed, the lower will remain dormant until the shoots are shortened. The exact length to which the shoots should be cut can only be determined by their strength. As a rule, weak growths may be shortened to 2 inches, medium to 4, strong to 5 or 6, more or less according to circumstances. If a great number of flowers for cutting for room-decoration should be preferred to a few large blooms, the strong shoots of established dwarf Roses may be pegged down instead of being closely pruned. Such depressed growths will flower from almost every joint; but newly planted Roses should be rather closely pruned the first year, not pegging down the shoots till the following season, when the plants will be firmly rooted, and can thus support the extended growths.

Earwigs and Chrysanthemums (J. A. E.).—Earwigs are highly destructive, devouring the young leaves near the tips of the shoots in summer, and eating the florets of the flowers when the plants are under glass in the autumn. Hollow bean stalks, elder stems, or anything of that kind placed amongst the plants are often taken possession of by earwigs and should be examined every morning and the occupants taken care of; small flower pots with a little dry moss in them placed near the stems of the plants or fixed amongst them on sticks are also useful. But nothing equals a rigid personal search for the pests after dark, and every bloom intended for exhibition should be closely examined with the aid of a lamp at nine or ten o'clock every night. Earwigs are "on the move" then, but quickly hide themselves in the blooms, so that the light should be turned on suddenly, and a quick eye and nimble finger will do the rest. It is because the pests will lurk in full blooms in the daytime that traps such as those alluded to are not completely effectual. All the varieties in your list are good for exhibition, and you cannot do better than stage the largest, best formed, and freshest blooms you can cut at the time of the show. Golden George Glenny and Mrs. Dixon are the same, and these with others of the "Rundle type" are not always large enough, but are occasionally seen in the front rows of winning stands. You do not indicate how many blooms you wish to exhibit, and you cannot do better than turn to the reports of last year's shows, and you will see the names of the varieties in winning stands large and small. If you exhibit either blooms or plants, it is important that they be neatly and correctly named, and we strongly advise you to spell the names as you find them printed in the Journal or catalogues. There is no such variety as "Miss Hales," but there is a Mrs. Heale, which is probably what you mean, nor is there a "Blound Duty," which you have written for Blonde Beauty; and there are other curious inaccuracies in your list.

Planting Crocuses in Lawns (R. A., Athlone).—Your letter, dated the 3rd inst., is the first we have received from you on the subject. Crocuses and other bulbs are planted informally in the grass of some of the London parks. In some places they are in clumps not far from the margins of shrubberies, with a few bulbs dotted here and there singly between the clumps, so that when in flower they appear as if they had spread naturally from the borders for several feet into the grass. In other cases they are planted singly but informally—that is, not in rows, so as to form sheets of colour, the bulbs being inserted from 1 to 2 feet apart, more or less according as they are near or distant from the walks; the nearer they are the closer they must be put in for producing a good effect. The present is a good time for planting, squares of turf being cut out, the soil beneath well stirred so that water can pass from it freely, the bulbs placed in and the turf pressed in position again. In very poor or heavy ground it is very desirable to remove some of it and add fresh for insuring the growth and increase of the bulbs, but in many lawns that is not necessary provided the soil is stirred and sand is added if of a heavy nature. Some persons simply make holes in grass with pointed sticks, press in the bulbs and tread in the grass over them; but that is not a good plan, as they are then practically suspended in the pointed cavities; and these in firm wet ground act as so many miniature water traps, preventing the growth and causing the decay of the bulbs. The better the soil is and the more careful the planting the more satisfactory will the results be, as bulbous plants cannot increase and multiply in unsuitable soil. Lawns in which bulbs are planted should not be mown in the spring until the leaves of the bulbous plants are matured and commencing to decay.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (J. F. C.).—Striped Beefing. (V. Martin).—1, Cellini; 2, Reinette de Canada; 3, Summer Pearmain; 4, Hoary Morning; 5, One of the Crabs. (D. J.).—1, Sam Young; 2, Greenup's Pippin; 3, Golden Harvey; 4, Dutch Codlin; 5, Minshall Crab; 6 and 7, uncertain. (N. H. Pownall).—Pears:—1, Beurré Coloma; 2, Autumn Nelis. Apples:—1, Rosemary Russet; 2, Adams' Pearmain. (Joseph Lane).—1, Hollandbury; 2, Summer Beurré d'Aremberg; 3, Beurré Clairgeau. (P., Surrey).—2, Carel's Seedling; 4, Flower of Kent; 5, Summer Pippin; 6, Braddick's Nonpareil. (W. G.).—1, Cellini; 3, Grosse Calebasse; 4, Baronne de Mello; 5, Flemish Beauty. (Oakfield).—4, Hubbard's Pearmain; 5, Court Pendu Plat; 6, Dumelow's Seedling. (J. E. R.).—1, Paradise d'Automne; 2, Swan's Egg; 3, Bois Napoleon; 5, Winter Nelis; the Apple is Sweeny Nonpareil.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (W. E. B.).—1, Lastea Sieboldi; 2, Gymnogamma tartarea; 3, Lastrea glabella; 4, Asplenium palmatum; 5, Nipholobolus lingua; 5, Polystichum capense. (C. C. Arnsia).—1, Impatiens cristata; 2, Lysimachia lanceolata; 3, Galega officinalis. (A Young Gardener).—1, Tradescantia zebrina; 2, Echeveria retusa; 3, Sempervivum arboreum variegatum; 4, Selaginella Kraussiana; 5, Euonymus japonicus medio aureus; 6, Cordyline indivisa. (W. C.).—Eccremocarpus scaber.

COVENT GARDEN MARKET.—OCTOBER 7TH.

SOME LESSONS OF THE YEAR.

GREEN manuring has again been done as extensively as possible, especially upon two poor farms where the land was so foul that when they came into our hands last April an excessive proportion of land had been left for a long fallow. Prompt measures were at once taken to clean and sow as much of it as possible with White Mustard, selected in preference to other green crops because of its quick growth. Fairly strong growth from the first sowing upon poor land is insured by the application of a hundredweight of nitrate of soda, and then by ploughing in the green crop when it is in flower, and repeating the process without the nitrate of soda, we impart an ample store of fertility to the soil. Avoiding nicety of calculation, the high value of green manuring may be shown by the fact that the ordinary green crop of an acre contains about half a hundredweight of phosphoric acid, a hundredweight of nitrogen, and a hundredweight of potash. Now, to plough in such a dressing of manure is to enrich the soil sufficiently to insure, so far as manure can do, a full crop of either corn or roots; but when it is remembered that by an immediate second sowing we may add considerably to this rich store of fertility in the soil at a much less cost than was entailed upon us by long fallows, surely it should require no argument to induce a general adoption of a process so clearly to every farmer's advantage.

Charlock was very plentiful this year in every county we visited. What was done to combat and overcome this pest, which is spreading far and wide so fast as to be literally a growing evil? We have already called attention to our own process of eradication, and may usefully do so again. As much land as could be dealt with in the fine weather with which we were favoured last autumn was pared and all the foul rubbish burnt. It was then ploughed, and early this spring it was sowed with White Mustard, as we had enough ashes from the autumn fires to afford a moderate dressing before the ploughing. No nitrate of soda was used. Up sprang the Charlock and Mustard together, and when this mixed growth was in full flower the whole of it was ploughed in and Mustard again sown. Another crop of Charlock came up with it, and the process of ploughing in was repeated. It was then optional for us to do this a third time; and although a third sowing may suffer from drought, yet if there is any reason to suppose more seed of Charlock can be stirred up it ought certainly to be done. We thus get rid of an enemy in the best way of all by making a friend of it, for Charlock is very beneficial to the soil when ploughed into before it has run fully to seed.

We greatly deplore the strong hold which Charlock has been suffered to obtain in the soil, and would urge upon every farmer the importance of destroying the first few plants, from which tens of thousands so soon spring.

Late-sown root crops have again suffered severely from drought, especially Mangolds, but those sown early in the season got so strong a hold of the soil as to suffer little if anything from drought. We have also seen some fields of roots sown much too wide apart. Sow early in fertile soil, and only have the rows sufficiently wide apart for a careful use of horse hoes, and then a quick strong growth will follow, so that the large leaves will soon meet across the rows, tending so materially to screen the soil from the direct action of the sun's rays as to check excessive evaporation of moisture from it. We do not forget that of Mangold sown early in April a small per-centage are apt to run to seed, but the loss is trifling in comparison with the gain upon the entire crop.

Although the experience of another year confirms upon the whole our objection to speculative farming, yet we never would oppose a moderate trial of anything at all likely to relieve us somewhat from the pressure of hard times. Maize, for example, has been grown successfully for silage, but we have also seen it used beneficially in the green state for cattle, and its culture for this purpose is spreading fast in the eastern counties. The idea that it would prove indigestible to animals if used green proves erroneous, due care being taken to use it before the stems become hard and tough, and farmers hail with delight a plant of such easy culture, yielding full 30 tons an acre of tender, rich, juicy succulent food, which is cut and carted from the field on to the pasture for cattle. It is not sown till June, and therefore forms an admirable second crop for land sown with White Mustard early in the year, as we have shown.

Self-binding reaping machines have done such good work this season that the general use of this wonderful labour-saving appliance is only a question of time. To get through the corn harvest in half the time it used to require is now easy by the aid of self-binders. Without them many a man has incurred a severe depreciation in the value of his best Barley through its exposure to heavy rain after it was mown and left lying in the swathe.

The importance of land drainage has again been so forcibly impressed upon us that we must not omit mention of it here. The doing of it may appear costly, but depend upon it the outlay brings a speedier return, a larger interest than almost anything else we can do for the land. Without it all we can do is comparatively useless; with it good culture is almost certain to be rewarded with success, bountiful and rich as is possible to obtain from mother earth.

WORK ON THE HOME FARM.

The sowing of winter Beans has followed that of Rye and winter Oats closely. Wheat-drilling has also begun, and autumn work upon the land is now in full swing, so that what with this work and corn-threshing we are very busy. Particular attention is being given to careful preparation of corn for market, so that if possible the bulk may be slightly superior to the samples rather than inferior. We pay close attention to this matter, for confidence once shaken concerning it is not easily restored. Barley yields well, and the price realised so far may be stated at a mean of 34s. per quarter, which to those who are so fortunate as to have grown six quarters an acre is a paying price, and it must not be forgotten to what good account the straw may be turned for chaffing. For this same reason Oats may also be regarded with a favourable eye. We never can agree with those who are wont to assert that such and such land is not an Oat soil without striving to ascertain wherein it is deficient. If soil does not contain the elements of fertility necessary for the food of the crops we desire to cultivate, is it not worth while to make good the deficiency? Of course it is, and we must determine to find out all about the requirements of each crop, and the precise nature of the soil we have to cultivate, avoiding, of course, all rash experiments and extravagant expenditure, as indeed true knowledge of these important matters enables us to do. Again we say, let us strive more and more to combine science with practice, and see how much more we can wrest from the soil, and how little we can put into it in the way of ntriment to enable us to do it. May we not usefully add the oft-taught lesson—drainage, mechanical division, timely culture, judicious applications of manure, and careful cropping must all go hand in hand if we are to still aim at being successful farmers? Pray let us be teachable, earnest, energetic, and hopeful, for it is altogether contrary to

our national character to submit tamely to hard times. Every step must be carefully weighed now, and there must be no wasteful expenditure of time or labour. This last is a matter demanding particular attention at this season of the year, when a large staff of men cannot be required on a farm. Get the bulk of the corn threshed as soon as possible, but pray don't thresh the Wheat too soon, but give the grain time to barden, and then our earnest hope for higher prices may in some measure be realised.

THE SEED HARVEST OF 1885.—The peculiar season we have experienced has had the result of retarding the development and ripening of all kinds of seeds, and the report we are enabled to offer at date of writing is consequently not quite so comprehensive as that we are accustomed to make, but the general estimates we have embodied may be relied upon.

Red Clover.—In consequence of the dry and somewhat irregular season, the English crop is later than usual, and it is expected that the great scarcity of animal food from the same cause will induce many growers who had intended to take seed to convert the crop into cattle food. The low prices also realised last year has led to a smaller acreage than usual being left for seed, so that it is not expected the English crop will be a very large one. The reports from France, Italy, Hungary, Denmark, and other producing districts speak of an indifferent output, the extreme drought having greatly prejudiced the prospects, and everything depends upon a good rainfall, which at the time of writing has not been generally experienced. From America the reports are not propitious: in fact, the estimates of the crop are so short that it is expected large purchases of European seed will have to be made to meet the deficiencies for home consumption.

Cow Grass.—The limited crop of this article, the production of which (in reliable seed) is entirely confined to England, promises to be a fair average, with a quality equal to that of last year, and values will probably open at last season's closing prices. The importance of this crop is being more recognised every year, inasmuch that foreign Cow Grass is always of doubtful quality, and does not compare favourably with best English samples.

White Clover.—There is a fair average crop of English seed, which is expected to be harvested generally in good condition. Reports from Germany, France, Hungary, Netherlands, &c., and other continental producing districts, point to the crops being less plentiful than last year. The quality all round is expected to be quite up to last year's average, and the ultimate output may yet exceed present expectations.

Alsike.—Some very nice English samples are coming forward, and will be sure to command good values, as the crop of this article on the continent is smaller than it has been for several years. Canadian and American reports are a little more satisfactory, but the small quantities these districts produce for export have no effect upon the general values or supplies.

Trefoil.—An average crop both in English and foreign seed, and reasonable prices are at present asked for bright and bold seed.

Lucerne.—This crop is likely to be a fair average one.

Timothy.—Reports not yet perfect.

Italian Rye Grass.—The English and Scotch crops have been secured in fine condition, and quality will be above the average. Values are at present ruled by reasonable prices.

Perennial Rye Grass.—This is also an abundant crop in excellent quality, and can be bought at present time upon favourable terms.

Rape.—Is better in quality and lower in value than for many years.

Swede and Turnips.—In quality exceedingly good, but the crops have come in very short in many districts. Values may increase as the season advances.

Mustard.—A good average crop, but an exceptionally brisk demand for home sowing for spring food has caused values to harden considerably.

Canary and Hemp.—Reports not yet perfect.

Natural Grasses.—These may be considered satisfactory as to average crop, and samples generally possess higher standards of purity than they have shown in previous years. There is necessarily a great range of values in these articles, as the price entirely depends upon vitality and purity. As usual, there is an abundance of low quality seed upon the market at all sorts of prices.—JAMES CARTER & Co., 237 and 238, High Holborn, London.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

27th.—Fine autumn day.
28th.—Very fine.
29th.—Rain early, dull and overcast throughout, but much warmer.
30th.—Dull morning; rain in afternoon and evening.
1st.—Fine day, but very slight shower in afternoon.
2nd.—Dull, with brief bright intervals; rain and wind at night.
3rd.—Glorious morning and fine day.
The temperature continues to fall, and is this week considerably below the average, with sharp white frosts on 27th and 28th. September proved a very wet month, the total being 4.30 inches.—G. J. SYMONS.

17	S	
18	SUN	TWENTIETH SUNDAY AFTER TRINITY.
19	M	Sale of Bulbs at Stevens' Rooms, Covent Garden.
20	TU	
21	W	Pear Congress at Chiswick to November 4th.

POTATOES.

ALTHOUGH the Potato is beyond question the most important of all root crops, a greater amount of ignorance prevails concerning it than any other crop of the garden or the farm, not ignorance in culture, which has much improved of late, but ignorance on the character and qualities of the greater number of the varieties that are now in commerce, and many of which have become prominent by the mention of their names in prize collections at exhibitions. No doubt there are individuals who know all about these—their habits of growth, cropping, quality when cooked, and the period at which they are ready for lifting; but the general public, that is, the great majority of Potato growers, do not, and it does not appear to enter into the minds of those who are competent to impart information to enlighten on the very plain yet decidedly important points indicated.

It appears to be taken for granted that "everybody knows all about" such now popular varieties (for exhibiting at least) as Adirondack, Vicar of Laleham, Cosmopolitan, Reading Russet, Snowdrop, Edgecote Purple, The Dean, Prizetaker, and some others that appear to be included in most collections in which they can be staged; but so far from all gardeners even, not to say amateurs, being acquainted with what may be termed the fashionable sorts, they know practically nothing about them, and there are thousands of persons who would receive gladly such knowledge as is possessed by experts if they should not consider it beneath them to convey rudimentary instruction to the inexperienced. By experts is meant persons who have cultivated the several varieties whose names are familiar, and who are intimately acquainted with their habits and properties.

It is true that a practice has become established of cultivating and cooking new varieties in the Royal Horticultural Society's Gardens at Chiswick before they are considered eligible for receiving certificates of merit at the International Potato Exhibition, that has now become an event of the year. It is impossible to speak too highly of the excellence of that plan, and the reports that are published are valuable, as the character of the tubers of each variety, its productiveness and quality, are indicated with sufficient precision to be comprehended by most persons; but something more appears to be needed to render the reports complete. For practical purposes it is not only important to know whether the varieties are dwarf, medium, or strong in growth, but much more so to be acquainted with the period at which the crops are ready for lifting, say July, August, or later. In the case of some varieties an idea is given as to their habit of growth, but that point is by no means made clear with the whole of them, and it is very rare indeed that the period of ripening is mentioned at all. Yet this is exactly what intending cultivators want to know.

The questions that are asked in respect of new varieties are, "Are they good and heavy croppers? what height do they grow? and what time are they ready for digging?"

Knowledge as to the approximate height is necessary for determining the distance of planting in order that justice may be done to the varieties without wasting ground, and information as to the time of ripening is not less required for determining the positions, so as not to interfere with after-cropping. In gardens in which land for growing Potatoes and other vegetables is limited it is quite as important to know when crops will be ready for removal as it is to know when they should be inserted; and in point of fact, far more mistakes are made through ignorance of the former point than the latter. An instance may be given, and when one is seen and recorded dozens of a similar character occur, but are not publicly alluded to. A gardener being satisfied about the general good qualities of Reading Russet and Reading Hero planted a border with them last spring, on the assumption that the ground would be vacated in time for sowing with winter Spinach, the demand for which is considerable. He has been disappointed. The first-named variety ripened soon enough—indeed, sooner than was expected; but the Hero continued growing so long that it became a question as to sacrificing the crop of it or having only half a supply of Spinach, and the latter course was adopted, with what results time alone can prove. The gardener has chosen what he considers the lesser of two evils, and while he says he expects to be "much bothered," he hopes to "get over it." This may appear a trifling matter, but what may be trivial in one case is often serious in another, and it is certainly very desirable that cultivators should know when the ground occupied with Potatoes will be at liberty for a succeeding crop.

For years I have been engaged where Potatoes are grown as extensively and perhaps as well as in any other district in the kingdom. The growers, though relying mainly on sorts of proved usefulness, are yet greatly interested in what is being done in raising new varieties, and over and over again I have had questions put to me respecting them that I could not answer, because I have not yet been able to try a great number of newer varieties, while those who have grown them have not perceived the necessity of giving full and plain information respecting them, on the ground, probably, that it is not needed. That is a mistake, and the plainer the subject the greater is the need for precise instruction, because what are regarded as simple matters are on that very account so apt to be overlooked.

With the object of becoming acquainted with some of the newer and most popular Potatoes I visited the great Show at the Crystal Palace last week, and noted the varieties above named were very numerous and fine, but when asked to describe their habits and season of ripening I am not able to do so. Are they, or any of them, likely to be more profitable to grow than Myatt's, Regents, and Magnum Bonums? That is what many persons desire to know. There is no doubt a great deal of pleasure derived from growing a number of varieties that may not be of value save for exhibition. It is very far from my desire to seek to deprive anyone of the enjoyment of growing such varieties for that purpose alone, or for raising seedlings, and thus adding to the bewildering number of sorts; but as, after all, Potatoes, broadly considered, are grown to be eaten, it seems important that the peculiar characteristics of the fancy sorts should be made clear to all, and it should never be forgotten that it is the most ignorant who are most in need of instruction.

But though some varieties may be grown for their appearance alone, productiveness with quality are now recognised as the chief essentials, as it is observable that only those which were accorded three marks each for those properties in the Chiswick trials were honoured with certificates at the Exhibition; and in future it may be taken for granted that new varieties thus honoured will possess sterling merit for commercial purposes, but some time must necessarily elapse before they can be increased sufficiently to enable their being sold at such prices that they can be cultivated on a large

scale. Yet surely some of those above mentioned, with others, the names of which are familiar to readers of your Journal, ought to be in some way superior to the "old sorts;" and if not these great Potato exhibitions, interesting as they are, and much as they may have done in stimulating growers to exercise more care in the selection and preparation of "seed" tubers, and to devote greater attention to culture generally, cannot be said to be completely successful. Either six or seven "International" Shows have been held, I forget which, yet very few varieties indeed that have been introduced to the public by their agency and recommended by their authority have taken a commanding position as contributing to the national food supply. The one Potato that has spread over the land in acres, and is poured into the markets in tons, is the Magnum Bonum, and this it has done entirely on its own merits, for I have seen it stated it has not been "certificated" at any of those Shows. It appears time, in the judgment of plain men, that some other of the comparatively recent introductions that have figured in prize lists should have a higher mark of approval—namely, a wide public endorsement of their merits for general consumptive purposes.

At the Exhibition alluded to the pinkish round variety Adirondack was conspicuous in several classes, and judging by appearances it would be regarded as a thoroughly useful variety, but is it so? Is it a great cropper and of good quality, of medium or strong growth, and what time ready for lifting? Equally commanding was the Vicar of Laleham, which must have had time to develop its qualities, yet "all the world" does not know its characteristics in those respects. Its rival in appearance and colour, the Dean, has of necessity not been so fully proved, yet some growers must know whether it is likely to be a serviceable variety or not. And what in those respects is known of the beautiful white kidney Snowdrop, the larger Cosmopolitan, Edgcote Seedling, and Edgcote Purple? There has been time to prove those and others, and it is clear that many persons grow Reading Russet, for exhibition at least, and ought to be able to testify to its usefulness for general garden and field culture for consumptive purposes. Snowdrop is the most attractive white kidney Potato I have seen, and if it is as good as it looks must be a great acquisition.

Some of the newer varieties exhibited at the Palace were all that could be desired in appearance, and as they have presumably been tested at Chiswick we must take them to be good in other respects, still some particulars regarding them would be acceptable to general cultivators. Chancellor was very fine as a white roundish variety, respecting which information would be useful. Prizes were taken in the white round and white kidney classes with Chancellor; are these two varieties of the same name, or were they different forms of the same variety? There seem to be two General Gordons, one of which was certificated and the other not. It is almost certain that confusion will arise sooner or later, and disappointment be experienced in respect of these. There are also two Bountifuls, Fenn's and Fidler's, but as the raisers' names will lapse in the course of culture, there will eventually be some difficulty in telling "t'other from which," and the practice of giving the same names to distinct varieties should be discontinued.

Harvester, Prime Minister, and M.P. were white rounds that commanded attention, and particulars respecting them of the nature indicated would be very acceptable to a large number of cultivators who are on the look out for something equally good as the Regents, but more productive and reliable, Schoolmaster not proving satisfactory in some districts and by no means equal to the old favourite just mentioned. Amongst all the fine-looking Potatoes now arranged so temptingly at shows, some of them must be good and profitable for growing on a large scale as staple table and market sorts; indeed it is not too much to hope that a few may excel those in general cultivation, but the virtues and habits of the newer sorts appear to remain in obscurity too long, and the

ignorance of the majority of Potato growers ought, as far as possible, to be dispelled by persons who can enlighten on this important subject.—A COUNTRY GARDENER.

PLANTING FRUIT TREES.

THE time will soon arrive for those who intend planting fruit trees to arrange about proceeding with the work. The first consideration will be what to plant, and the next the preparation of the ground. Most gardeners have probably selected the varieties they wish to have, but many perhaps are in doubt as to what to choose so as to form a succession or meet the demands of a certain part of the season. I will name at the end of this article a succession of Apples, Pears, or Plums suitable for the garden or orchard, but it must be borne in mind that some varieties which succeed well in one part of the country are not so suitable in another. Gardeners should endeavour to ascertain what varieties are known to succeed well in the district before they decide.

The preparation of the ground for fruit trees is important. Good drainage is indispensable, as without it the trees will not thrive, and if the ground is not drained naturally drains must be provided. Anyone who has noticed fruit trees planted on well-drained land will have perceived how healthily they start into growth, and what good crops of fruit they perfect; but on the other hand, when the ground is not drained the trees never start into clean growth, but become starved and subject to all the ills that attack fruit trees when the ground is a cold and sodden mass. Some soils are much more adapted for the culture of fruit than others, being both deep and fertile, and when this is the case the labour attending their cultivation is reduced to a minimum. The preparation of the ground in this case, and when the trees are to be planted not too close, is to allow each tree a station of 5 or 6 feet, working the soil to the depth of 2 feet. When the tree is planted place a little turfy loam and well-burned garden refuse about the roots, which will help to give the tree a good start. If the ground is being prepared for cordons, or the trees are to be close to each other, but to be eventually thinned, the whole space of ground should be worked.

In many instances the soil is not well adapted naturally for fruit trees, but it must be bad indeed if Apples, Pears, or Plums cannot be brought to succeed fairly well. When the soil is not very good, or the place the trees are to occupy is an old garden which has been under cultivation for a number of years, the ground must be worked to the depth formerly stated, but do not bring the subsoil to the surface if of a poor and hungry description. If the soil is heavy burnt clay and garden refuse and old lime rubbish should be added, and fresh loam and burnt refuse may be placed about the roots.

Early planting is desirable, as besides being better for the trees, the ground will not become wet from the autumn rains. It is also important to plant the trees as quickly as possible after they are received, but endeavour to choose a fine day. Cut off cleanly all bruised ends or portions of roots, and remove enough soil to permit the roots being spread out to their full extent. Place the fresh soil first among and over the roots, and then level the original soil, treading it evenly and rather firmly, but care must be taken that it is not in a wet state. Spread a coating of dry litter on the surface, which will keep out frost and drying winds. Securely stake standards and pyramids if exposed or likely to be injured by wind, but trees against walls should not be nailed in until just before the buds start, securing then, however, so as to prevent injury to the branches from being rubbed against the wall.

The form a tree is to grow in will depend upon circumstances, and it can be understood how unwise it would be to plant standard trees in a kitchen garden, though it is generally the place where they have to be grown. The aspect is another consideration, for if the site is open to the full force of the winds it would be unwise even to plant standards in an orchard. Standards are grown when the orchard is laid down to grass and sheltered, but when the site is exposed bush trees should be planted, keeping the ground clean through surface-stirring, and give a good coating of farmyard manure annually. Other crops could be grown between the rows until the trees require all the space. Growers for market generally have their fruit trees on worked ground, and standards and bush trees are generally adopted. Currants, Gooseberries, and Strawberries are grown between them until the permanent trees require the space. In kitchen or fruit gardens connected with private places Apple trees must be grown in the form of bushes or pyramids, Plums and Cherries the same, or if desired especially large and good

for dessert purposes against walls, when fan-training is the form usually adopted. Only grow the earliest or mid season varieties of Pears in the open, unless the situation is favourable, as varieties in use from November onwards are best grown against walls with a south-west or south aspect.

The cordon system of growing fruit trees should be generally adopted in gardens, especially in those of a small size, and I am glad to see that cordons are being favourably commented upon by gardeners and amateurs generally. Apples, Pears, Plums, and Cherries may be grown on this principle, but it is for Pears that the system will be carried out generally.

SELECT VARIETIES.—APPLES, *Dessert*.—Irish Peach, Margaret, Mr. Gladstone, Kerry Pippin, King of the Pippins, Margil, Cox's Orange Pippin, Adams' Pearmain, Ribston Pippin, Pine Golden Pippin, Scarlet Nonpareil, Duke of Devonshire, Kedleston Pippin, Court Pendu Plat, Mannington's Pearmain, Sturmer Pippin, Hubbard's Pearmain, Golden Russet.

Culinary.—Kewick Codlin, Duchess of Oldenburgh Warner's King, Blenheim Pippin, Lord Suffield, Stirling Castle, Small's Admirable, Golden Noble, Cellini, Greenups Pippin, Ecklinville, Northern Greening, Loddington, Rymer, Dumelow's Seedling, Wormsley Pippin, Minchall Crab, Alfriston, Winter Quoining.

PEARS.—Beurré d'Amanli, Comte de Lamy, Beurré Superfin, Louise Bonne of Jersey, Beurré Hardy, Marie Louise, Doyenné du Comice, Pitmaston Duchess, Marie Louise d'Uccle, Beurré Diel. All the above Pears succeed well in the southern part of England when grown in the open. The following should be grown on walls—Beurré d'Arenberg, Winter Nelis, Josephine de Malines, Glou Morceau, Emile d'Heyst, Marie Benoist, Knight's Monarch, Passe Crassane, Bergamotte Esperen, Nouvelle Fulvie, and Olivier des Serres.

PLUMS, *Dessert*.—July Green Gage, Bryanston Gage, Green Gage, Jefferson, Kirke's, Coe's Golden Drop, Reine Claude de Bavay, Oullins Golden.

Culinary.—Early Rivers, Diamond, Victoria, Prince of Wales, Pond's Seedling, Prince Engelbert, Belle de Septembre, White Magnum Bonum, Yellow Magnum Bonum, and Autumn Compôte.

I have named a good selection of Plums, as I have found some varieties succeed better than others in different seasons. Some Apples bear good crops of fruit annually, and when this is the case it should be planted in quantity if it prove to be a good keeping variety.—A. YOUNG.

THE ROSE CATALOGUES.

LOOKING over the catalogues adds force to Mr. G. Paul's latest remark in his own—"There is much need of a good lot of first-class new Roses." I hardly ever remember such a lull in the announcements. Mr. Bennett makes no sign as to either offering Her Majesty or Mrs. John Laing to the English market, and for the rest there is nothing that stands out really prominent. I had hopes from Gloire Lyonnaise, but it seems doubtful whether this will be an exhibition Rose at all; most people seem to have found it single. It may possibly have been pushed on too fast, as I see M. Guillot, the raiser, vouches that on established plants it will be found good and double.

The admirable and exhaustive article of Mr. Girdlestone on the new Roses really leaves only little to be said. As far as my observation goes, the Honourable Edith Gifford T., almost a Devonensis, has been increasingly winning favour, and Grace Darling and Madame de Watteville are also fully approved. I have been greatly pleased with Comtesse de Paris, a most lovely soft rose colour, which I think is not much known; and equally disgusted with Madame Isaac Perrière, whose promising robustness verges close upon coarseness. Pride of Reigate, on the other hand, has been very beautiful, and is still a solitary variety. I observe another seedling, from the Gloire de Dijon, Etendard de Jeanne d'Arc (there ought to be a law that no Rose shall have more than two names), is favourably reported on by Mr. Girdlestone, and as a pure white Tea must be worth possessing. Certainly Madame Gloire may well be proud of her youthful progeny. "*Mater pulchra filia pulchrior*," may be said of several of them, they will soon require a class if not a box to themselves. This would be an excellent idea for a prize at the National. My last remark shall be the consolation to be derived from two hot summers. A vast quantity of seed must have been successfully ripened, and in two or three years we may expect great results.—A. C.

PEN-Y-BYD MARROW—CUCUMBERS.

Now that the Marrow season is about over, and taking into consideration what an important part they play in the summer and

autumn vegetable supply, I venture to give my experience on the merits of Pen-y-Byd.

Our Marrows were all sown early in March and planted out under handlights about the middle of May, including, besides the above, Moore's Vegetable Cream and the Long White. The last week in June the first Marrow, a Pen-y-Byd, was cut, and since that time up to a week ago this variety has given us a supply of Marrows which have been preferred to either of the others named. It is a most prolific variety, in several instances carrying a couple of fruits from one joint, not large, but of such a size that they can be cooked whole, a mode of cooking this vegetable which is said by many to be preferred to any other. As to quality, I may state that my employers think so highly of it that when having visitors they have asked for the best Marrows, adding, "The long ones will do some other time." For a gentleman's table I consider it a decided acquisition, and should, I think, be grown in every garden where this vegetable is esteemed. I congratulate Mr. Muir, the raiser of the variety.

Cardiff Castle Cucumber, which I have grown since it was first sent out, has again proved a sterling variety. I can only find one fault, and that may be the grower's fault, as with me it grows rather long jointed; in other respects I consider it the best. Since Rollison sent out Telegraph so many people have sent out Improved Telegraphs, and some much more improved than others, that a few remarks may not be out of place on the subject. During the last few years I have tried several of these so-called Improved Telegraphs, and this season I have found what I consider the finest. I was strongly advised by a friend to try Roffey's Improved Telegraph, and did so, and have found it to be the best I have as yet grown in every respect. I had occasion to be at Croydon a few weeks ago, and having half an hour to spare, I went to see Mr. Roffey, who was busy amongst his Cucumbers, and a fine sight they were. Two houses about 40 feet long were hung with Cucumbers for seed, vary from 18 to 25 inches in length. In many instances two fine fruits hanging from one joint, and in one instance three. Mr. Roffey is evidently an adept at Cucumber-growing. I remarked that they appeared to be growing in pure loam. He at once told me that he did not use much manure, adding "hoofings is the best for Cucumbers, the sweepings from a blacksmith's shop."—W. W. B.

FRUIT AND PLANT HOUSES.

SINCE 1850 there has been a rapid increase of horticultural erections, showing great improvement in the quality of their construction. The impetus was due in a great measure to the repeal of the duty on glass and the increased prosperity of the nation; but the greatest impetus was given by the diffusion of horticultural information. In 1850 the late Mr. Thomas Rivers published "The Orchard House," in which was shown exactly what was required by many—viz. (in Mr. Rivers' own words) "a place requiring but little expense to erect, but little experience and attention to manage, and yet giving most agreeable results." To Mr. Rivers belongs the credit of marking a new era in the construction of horticultural buildings. His plan of cheapening construction caused the erection of houses much better adapted for fruit and plant culture. Instead of conservatories with stone or brick mullions, leaded lights of tiny panes, little or no provision for ventilation, and opaque roofs—plant dungeons—we now have panes of plate glass as large as hundreds of the displaced pigmies, a roof remarkable for its flood of light, little wood or less iron, and ventilation we have in dome, cupola, or lantern. In plant and fruit houses the revolution is quite as striking as it has proved beneficial. Instead of heavy rafters supporting framed lights with many sash-bars, glazed with small panes with wide dirt-holding laps, and a clumsy system of ventilation, we have houses constructed with less than half the strength of rafter, one-third the number of sash-bars, and the frames are gone altogether, so that we get fully two-thirds more light. Fixed roofs, a maximum of light, and thorough ventilation are the prevailing features of the new system, which in some modified form or other embodies the principle enunciated by Mr. Rivers, in a majority of the fruit and plant houses of the present time.

Though the system introduced in 1850 is very generally followed, we still have houses constructed upon the old or frame-light system. It is of these two systems that I propose to offer some remarks, especially on their construction, as it appears to me to relate to successful practice. I think that whenever a house is to be built the gardener who will have to answer for the crops that by its means are to be produced should be consulted upon the subject by his employer. It would at least give him an interest which otherwise he does not feel. Gardeners, I may be told, do not as a rule study plant or fruit-house construction. Then they should do so, for, whatever may be stated to the contrary, they ought to know

what kind of structure is most suitable for growing certain crops in the most satisfactory manner, and also be able to form an estimate of the value of materials, so as to enable him to have structures erected in the most economical manner consistent with stability. He ought to be able to state concisely the kind of house, the material it is to be constructed of, the ventilation essential, and heating surface required; in fact, give a ground plan and section to scale, with general specification of requirements embodying his employer's instructions. If he cannot proceed that far, then I grant he has no right to be consulted in the matter.

Horticultural structures are of various kinds, which I shall pass briefly in review, to which certain principles apply. First, whatever the structure may be it should be impervious to wet; second, cold air should be prevented from entering, and warm air from within escaping as much as possible; third, the means of ventilation must be ample; and fourth, the fullest admission of light secured, which will be the last treated of when we come to the details of construction.

The great factor in the growth of vegetation is light—solar light and heat—about which it is only necessary to observe that in passing through glass the rays of light lose much of their force as regards the vegetation on which they act, and the distance the plants or foliage is from the glass still further diminishes the energy of the solar rays. The intensity of the action of the solar rays depends on the angle at which the rays fall upon the surface of the glass, and which is known as the angle of elevation. This angle is now but little taken into account in the construction of fruit and plant houses. The chief thing now considered is an angle of elevation that will insure the throwing off of wet outside, and prevent drip inside; but it is well not to lose sight of the fact that when the sun's rays fall perpendicularly upon the glass very few rays are reflected, and when they fall upon it in a very oblique direction more rays are reflected than pass through it; consequently we get nearly all the sun heat by one and lose them by the other. Although much has been made of the angle of incidence, with our improved mode of applying artificial heat it need not enter much into the consideration of the horticulturist. Nevertheless, it is important that the heat in any structure should be distributed as equally as possible throughout the whole of the interior. The higher the pitch of the roof the greater the accumulation of heat in the upper part of the angle, and the lower the pitch the less the difference in the temperature of the house at the top or bottom. For these and other considerations it becomes advisable to keep the slope of the roof as low as is consistent with the admission of light and the free escape of rain; also to protect the interior from drip. For general purposes an angle of 35° to 40° is suitable, and very generally applicable, from which there need not be any deviation, unless in the case of houses employed for early forcing, when a sharper pitch on account of light, and quite as much for preventing accumulations of moisture on the glass outside or inside, yet this need not be more than 45°—a sharp pitch indeed, and quite enough for any plant to be forced during winter in our climate.—G. ABBEY.

(To be continued.)

CHRYSANTHEMUM NOTES.

CHRYSANTHEMUM SOCIETIES' SCHEDULES.—Several of these are still coming to hand, and this week we have received the following:—The Brixton Hill, Streatham, and Clapham will hold their show on November 4th and 5th, the usual classes being provided. The Richmond Society will hold a Chrysanthemum show this year on November 5th and 6th, in Castle Hotel, when good prizes will be awarded in forty-eight classes. In one class three very substantial prizes are offered—namely, £10, £6, and £4, for forty-eight blooms, distinct, twenty-four Japanese and twenty-four incurved. These should induce some of the best growers to enter, and close competition may be expected. The Kingston Show—one of the events of the season—will take place on November 10th and 11th, when the third champion challenge vase will be placed in competition for the second time, the winner last year being Mr. Molyneux, gardener to W. H. Myers, Esq., Bishop's Waltham, who will no doubt do his best to repeat his success this year, but it is rumoured that he may expect a formidable opponent to contest the honours with him. In the other classes the customary liberal prizes are offered. The second Huddersfield Exhibition will be held on November 13th and 14th, in the Town Hall, prizes being provided in thirty-seven classes, the principal that for forty-eight varieties, twenty-four Japanese, and the same number of incurved, the prizes consisting of £10, £7, and £4. The Winchester Show opens on the 17th of the same month. The Northampton Show on the 18th, and at both numerous prizes will be given for cut blooms, plants, fruit and vegetables.

CHRYSANTHEMUMS AT THE INNER TEMPLE.—The extensive collection under the charge of Mr. Newton is this season promising unusually well, the growth being strong but not too luxuriant, while the buds are clean and swelling evenly. The show house at the lower portion of the Inner Temple Gardens, close to the Thames Embankment, is devoted to them, and the exhibition will probably, by the liberality of the benchers, be opened to the public at the end of this month. Many of the new varieties are represented, and visitors will have a good opportunity of judging their respective merits as compared with the older and proved sorts.

NEW VARIETIES OF CHRYSANTHEMUMS.—The continental growers are still sending out large numbers of new Chrysanthemums, and unfortunately these are not all so distinct as they ought to be. It seems as if they do not test them sufficiently before placing them in commerce, and in consequence when they are tried here many are discarded as worthless. Numbers will be submitted this season for certificates as usual, particularly amongst the Japanese, and it behoves those tribunals before which they are placed to exercise considerable caution before honouring them. There is an opinion that in the last two or three years certificates have been granted too freely, and the result is that some varieties upon further trial have not proved worthy of the award they received. The Floral Committee of the National Chrysanthemum Society will undoubtedly be doing valuable work if they restrict their certificates to really meritorious varieties, and this we may rely they will do. Chrysanthemum growers will then know what new varieties they can safely purchase to add to their collections.—B. C.

CHRYSANTHEMUMS AND THE FROSTS.—I have been looking for reports in the Journal of damage by the frosts of the 26th, 27th, and 28th of September, when the thermometer registered 26° each night. I have never noticed bedding Pelargoniums completely killed so early before; of course the more tender plants, such as Dahlias, are often cut off early. I am afraid some of our Chrysanthemum buds were injured. I have examined some of the side buds near the terminal one of some that had not been disbudded, and have found them quite blackened through. What effect will this have on crown buds that are much larger and more exposed, having no foliage close to them?—J. L. B., Leicester.

ARE CHRYSANTHEMUMS SEMI-AQUATIC PLANTS?—All know how partial Chrysanthemums are to moisture at the roots, but this query is suggested by the following circumstance. I planted a number of my own seedlings in front of a south wall, potted some of Mrs. George Rundle and Cullingfordi, and planted similarly an equal number. The cantalever, or eave shoots, commenced to leak in one spot over those named, especially Cullingfordi. I regretted this, as I had but one potted and one planted, being still new. It is two months since the leak commenced, and one of each has been almost continuously saturated. Instead of dying they seem to luxuriate in the moisture, and are much before those ordinarily treated of the same varieties. The foliage is rich, dark, and glossy, and the buds most promising; hence the inquiry.—W. J. MURPHY *Clonmel*.

TRENTHAM BLACK AND ALNWICK SEEDLING GRAPES.

I THINK you are quite right in your reply to Mr. McIndoe's question with regard to the above two Grapes. The Grape which I know by the name of Trentham Black, coming from a reliable source, has no resemblance to Alnwick Seedling, and it exactly answers the description you give of the true variety. The bunches are very long, rather loose, and (with me at least) a large percentage of small or stoneless berries. The berries are large, round, and colour well, and ripen a few days later than the Hamburgs. It is a very strong grower, producing large, dark green, leathery leaves, which turn yellow when ripe—not blotched red, like Alnwick Seedling, and the under side of the leaf is quite smooth, while that of Alnwick Seedling is downy. It is evident Mr. McIndoe has not got the true Trentham Black, and it would be rather strange if all the three Vines—Trentham Black, Alnwick Seedling, and John Downie—should prove to be the same.—A SUSSEX GRAPE-GROWER.

I SHOULD think there are no two Grapes more unlike than these. First of all, having for some four years seen Trentham Black at home and noted its characters well, I can never forget the sight it presented in the narrow upright glass cases as grown by the

late Mr. A. Henderson, who succeeded Mr. Fleming. Since then I have had it in my own care at various times, and have given it up on account of its not paying, it being too much like a Black Ham-burgh. It will keep, but does not improve by so doing. It is not particularly shy in setting, but is very faulty in stoning. The flavour of Trentham Black now and Alnwick Seedling would soon decide which is right; the first would be in season now, but not the latter.

Alnwick Seedling I had from Messrs. Osborn of Fulham, Mr. Robert Osborn assuring me he had the eyes direct from Mr. Bell, is not to be mentioned with Trentham Black only for its good keeping quality. In March it was a very peculiar beautiful eating Grape. I wish that Alnwick Seedling had the shape and form of bunch peculiar to Trentham Black. Having grown the two varieties on the same soil in the same house under the same conditions I can speak with confidence.—STEPHEN CASTLE, *West Lynn*.

WHITE CUP.

NIEREMBERGIA, or White Cnp, is a genus belonging to the Potato family, and closely allied to the Tobaccos, and had long been considered as belonging to the sub-tribe *Nicotianæ*, until Mr. Miers, who had given much attention to the variety of structure in this family, came to the conclusion that *Nierembergia* with *Fahiana* were sufficiently distinct to be separated from the section *Nicotianæ*, giving the name *Fabianæ*.

Fig. 52.—*Nierembergia rivalaris*.

owing to their having capsular fruits and other minor differences. In *Nierembergia* the divisions of the calyx are invariably upright and acute, not leafy, the corolla tube generally longer and more slender than in the *Petunia* section, although in the smaller-flowering species the differences are hardly patent to the general observer. The most prominent character by which this genus may be distinguished from the others is the shape of the stigma. It is like an inverted crescent, with small appendages curving round in front and closely adhering to, or clasping the anthers. Although the probable number of *Nierembergias* known is over twenty, there are less than half a dozen at present in cultivation, and only one of these may be said to be sufficiently hardy to stand our severe winters in the open air.

Nierembergia rivalaris (fig. 52), was found by Miers, about the year 1845, growing on the grassy banks of the Rio de la Plata, South America, "the prostrate branches creeping among the grass, above which rise its pretty white flowers." Indeed, under cultivation, and when well established, there are few similar plants that contribute so much in such little space towards the beauty of the rockwork or border as this little gem. Although it seems to prefer a rockery or a similar situation where its roots get curbed, it will do equally well on dry banks or flats, and a large patch I saw on the flat fully exposed was a sight never to be forgotten, so thickly were the large beautiful white cups studded among the leaves on short stalks like so many *Campanula*-shaped Mushrooms. Those not hardy in the open air may be used with great advantage indoors in

the shape of trailing or creeping plants. A hanging basket made with *N. gracilis* as an edging is extremely pretty, besides having the advantage of being permanent. Then there is *N. frutescens*, a strong shrubby species of considerable worth for a greenhouse or conservatory, as it makes fine hushes in a short time, flowering more or less incessantly. *N. rivularis* rarely grows more than an inch or two in height, having long prostrate creeping branches rooting as they spread away from the centre, which requires filling up occasionally. The leaves are alternate, oblong, blunt at the summit, on a long slender stalk; the corolla, shaped like a *Campanula*, is upright, about 2 inches in diameter, pure white, and very handsome. It flowers through the summer, and may be increased by division.—T. Y.

IS A TENANT'S GREENHOUSE A BUILDING?

On September 30th I was summoned by Mr. Elkington, district surveyor of Penge, to appear at Lambeth Police Court on a charge of erecting a greenhouse, 12 feet by 8 feet, in the district of Penge, without having given the notice required under the Building Act. I contended that this greenhouse was a tenant's fixture, and did not come under the Act, being made portable in every respect, boarded up to sill of sashes; standing on but not fixed to another sill or frame at bottom formed of 7 inch by 2½ inch deal.

I was advised to have wheels put on this greenhouse to save being compelled to comply with the Act, which states that all buildings shall have 9-inch brick walls with proper footings and concrete foundations, which, of course, I could not comply with, being only a tenant's fixture. Accordingly I had four wheels put on the bottom frame, so that the whole could be moved in one if necessary, or taken apart and stowed away in a shed if required. The result was that Mr. Chance (Magistrate) decided that this greenhouse, although not connected with the ground either by posts driven in or by brickwork under, but only laid on top of the earth, was a building within the Act, and gave it as his opinion that even *Cucumber* frames were not exempt.

I report this case to you feeling that it is a matter not to be trifled with, but should be dealt with promptly and decisively, and in the interests of flower growers generally I take the liberty of asking you to give this matter all the publicity possible. Having seen the uncertainty which exists among tenants and the gardening papers generally, I took the precaution of employing a first-class solicitor to defend the case, thus incurring considerable expense, the case being adjourned, and having to re-appear on Saturday, but it was all of no use; I was fined a nominal fine of 5s. and the cost of the summons, with of course, the privilege of appeal.

Now, this appeal will be of no use to me, but if your readers feel sufficient interest in the cause of tenants' rights as to having a greenhouse of their own, and will offer some assistance towards the cost of an appeal against this decision, I am quite willing to join in the expense and allow my case to be used as a test case in the interests of tenants and flower growers generally.

Should you deem this worthy of insertion, those of your readers who wish to help in this important matter may send their names, addresses, and amount they promise to contribute to Basil E. Greenfield, Esq., Solicitor, 17, Katharine Street, Croydon, and they will receive an acknowledgment in the paper they choose to name.

In writing please write the word "Appeal" on outside of envelope.—A. DENT, *Horticultural Builder, 118, Selsden Road, Croydon*.

[We insert this letter, but think it right to say we are advised that tenant's fixtures come under the Building Act, and if a tenant "cannot comply" with the Act, we fear he cannot erect a greenhouse in a position and district to which the Act applies. Those who think differently have now an opportunity of sharing in the settlement of a perplexed question of wide interest to amateur horticulturists who reside in the vicinity of cities and towns where Buildings' Acts exist. Mr. Chance's "opinion" that *Cucumber* frames come under the Act is not endorsed by us, as we fail to see that a frame is a building. The rigid enforcement of Building Acts is a great impediment to the erection of amateurs' greenhouses, and often presses heavily, if not unjustly, on nurserymen.]

BOUVARDIAS.

DURING autumn and early winter few plants so amply repay for labour bestowed on them as the *Bouvardia*. It is suitable alike for conservatory or for using in a cut state; its neat flowers, which can now be had in so many varied colours, are always admired. Though frequently treated as a stove plant I think that is a mistake, as much better results can be acquired by growing it in cold frames during the summer months, transferring it into warmer quarters when the weather becomes cold in the evenings. Under this treatment it makes stout firm growths, and eventually produces abundance of fine useful blooms, much superior to those obtained from plants grown in heat, which are generally inclined to make soft succulent wood, the flowers from which are inferior both in substance and colour.

In spring when the plants are starting into growth they should be taken out of their pots and all the soil shaken away from the roots, replacing them in pots somewhat smaller, using a compost of equal

parts loam and peat, with a good sprinkling of sand. They should be put into a gentle heat; a newly started vinery answers very well, and if kept syringed they soon grow freely.

If it is desired to increase the stock cuttings may now be had which will strike readily in a gentle bottom heat under a bellglass. Some prefer root cuttings taken off when potting. I have tried both methods, and prefer taking young growths: they strike easily and make better plants, at least this has been my experience. When the growths are 3 or 4 inches long the points should be pinched out to get the plants dwarf and bushy, and they should be attended to in this matter during summer, stopping them whenever sufficient growth has been made to allow of so doing.

As soon as the roots begin to appear at the side of the pot the plants will require repotting, using the same compost as previously recommended, with a small quantity of well-decayed manure and a little soot. Early in June they may be placed in a cold frame and kept close until they are thoroughly hardened, when air should be admitted on all favourable opportunities. Shade for a few hours during bright sunny weather. When the soil has become well filled with roots a little liquid manure applied once a week will prove beneficial. When the nights begin to get chilly the plants may be removed to a house where a temperature of 50° or 55° is maintained, which will assist in bringing forward the blossom, and where this heat can be had they will continue flowering for several months during the dull season of the year.—WILLIAM LITTLE, *Moncrieffe*.

THE ROSE APHIS.

I READ with some surprise "D., Deal's," review of the now past year's Rose season, on which he remarked on the general absence of aphids. My experience was so directly contrary to this, that I quite expected to see some letter on the subject in the Journal. A day or two ago I received a letter from one of the most successful Rose nurserymen in England, in which he writes—"With regard to the past Rose season I have found it as you state, the worst I ever had . . . At the end of July we had such a shower of green fly as to completely smother the plants. It was no use trying to clear them, so they remained until they took their departure. I think they remained nearly three weeks." I should like to hear the experience of others. Perhaps "D., Deal," is unusually happy in his surroundings. Verse tells us that St. Patrick

"Drove the frogs from out the bogs,
And banished all the serpents."

Is it possible that the vicinity of Royalty to Westwell Vicarage has had the same happy effect on the aphids?—H. B. B.

LATE GRAPES AND LATE CHRYSANTHEMUMS.

I NOTICE a suggestion has been duly proposed and seconded in your columns. Shall I be out of order in saying one or two words in support?

The suggestion is that a few prizes should be offered for late Grapes at our late Chrysanthemum Exhibition in January next, to be held at the Royal Aquarium, Westminster. I have but little doubt such a competition would prove both interesting and instructive, and am quite sure the Committee of this Society would be glad to give every possible facility towards carrying into effect the suggestion.

I should, however, like to have the opinions of some of our leading Grape-growers as to the number of classes, and for which varieties they would suggest prizes should be offered. The amount of the prizes I take it need not be very high, and the cost of arranging for the Show, as it is in conjunction with a show already provided for, would be nil. It will therefore only be necessary to raise a small fund just sufficient to pay the actual prizes awarded. I should be pleased to contribute my mite, and, should the suggestion find favour generally, most glad to co-operate with anyone in the matter.—WILLIAM HOLMES, *Hon. Sec., Frampton Park Nurseries, Hackney*.

THE suggestion that the National Chrysanthemum Society should provide a class for late Grapes is well worth the attention of the Secretary and Committee, and I hope we shall hear something more upon the matter. It seems to me that one class would be sufficient for the purpose, and three prizes might be offered, together with the Society's silver and bronze medals, for the first and second winners. This would increase the interest of the competition materially; and though a large display could not be expected, yet it would be useful, and it would moreover be a novelty to see an exhibition of Grapes in the middle of January. I should like to see some other opinions on this subject.—A.

STEPHANOTIS AND GARDENIAS.

IN reading the correspondence on this subject between Messrs. Muir and Jenkins, it has occurred to me, that though much may be said for

their different views of the question, both of them have somewhat missed the mark. The question as stated seems to be whether certain of our most valuable and ornamental stove plants are worth the trouble occasioned by constant washing, &c., to keep them free from mealy bug? The somewhat obvious query, Why grow bug at all? seems to have been overlooked. My advice to those who already have a stock is, Get rid of it as early as possible; and to those who fortunately have not, Be careful not to introduce it.

Some gardeners have an idea that certain plants, as Gardenias, Stephanotis, &c., breed mealy bug spontaneously. I have succeeded in some cases in upsetting this notion by showing them a batch of Gardenias 4 feet high and through, which have not been washed for years, and offering £10 each for all the bugs they could find. By starting with a clean stock and putting every new plant introduced through strict quarantine, we manage to grow Gardenias, Stephanotis, and Eucharis in quantity, and a collection of other stove plants, including Crotons, Dracænas, &c., all of which have scarcely ever been sponged, our annual saving in labour, &c., being reckoned in three figures. The case is more simple when commencing with clean houses, &c.; but that an infected place may be absolutely cleared has been proved by many of our best gardeners, and I could name a place under my own observation, which, to use a Nottingham expression, "snived" some years ago, but which is now perfectly free. Granted that the clearing process entails a period of general upsetting and hard work to begin with, followed by months of constant watchfulness, I hold that the result will well repay the outlay.

The constant washings needful to keep down bug are certainly detrimental to the health of the plant, and, in addition to the actual labour bill, the fact must be taken into consideration that mealy bug breeds the fastest, and therefore requires the most attention in the early summer months, the busiest and most critical season of the year to gardeners and nurserymen.

To sum up, it is possible to grow all and any kind of stove plant without this dreaded pest, no one will dispute that the method is easier, cheaper, and more pleasurable. Query, Why not?

I should like to add a note as to the glowing extract regarding the price of Gardenia blooms. If such extracts be quoted from local papers (which as a rule are proverbial for dense ignorance on matters horticultural) it would be less misleading if it were stated that Gardenias may now be sent into Covent Garden during several months of the year without realising more than 1d. or 2d. each, from which cost of carriage, salesman's commission, &c., have to be deducted.—CHAS. E. PEARSON, *Chilwell Nurseries, Nottingham*.

A MEETING of the Council and Committees of the Royal Horticultural Society was held at South Kensington on Tuesday, the 13th inst., Sir Trevor Lawrence, Bart., M.P., in the chair. The object of the meeting was to consider the desirability of holding an INTERNATIONAL HORTICULTURAL EXHIBITION AT SOUTH KENSINGTON IN 1887, and it was resolved that, with the object of obtaining a larger representation of horticulturists than was then present, another meeting be held on November 10th. The Council desire the co-operation of all who are interested in these matters, and invite them to take part in the proceedings of the forthcoming meeting.

— "J. U. S." writes—"MADRESFIELD COURT GRAPE, as I have seen it grown at Trentham and elsewhere, is one of the best flavoured and finest-looking mid-season Grapes in cultivation. I cannot understand 'bags of sugar and water' being placed before the rich, luscious, and piquant Madresfield Court, if all other conditions are equal as to finish, and Madresfield Court will and does finish well."

— THE meetings of the LINNEAN SOCIETY will be held at Burlington House, Piccadilly, W., on the following dates:—1885.—Thursdays, November 5th and 19th; December 3rd and 17th. 1886.—January 21st; February 4th and 18th; March 4th and 18th; April 1st and 15th; May 6th and (anniversary) Monday 24th; June, Thursdays 3rd and 17th. The chair will be taken at 8 o'clock in the evening, excepting on May 24th, which is appointed for the anniversary elections, when the chair will be taken at 3 o'clock in the afternoon. The library is open daily from 10 o'clock till 5 o'clock in the afternoon, and the reading-room, adjoining, from 10 A.M. to 6 P.M., but on days of Council meetings and on Saturdays only till 4 P.M.

— A WELL-KNOWN exhibitor, MR. J. CHILD, gardener at Garbriand Hall, Ewell, is, we are informed, about to leave that establishment owing

to some changes in the family. Mr. Child has been fourteen years at Garbrand Hall, and bears the reputation of a good practical gardener.

— MR. ROBERT OWEN has sent us "some blooms of TUBEROUS BEGONIAS gathered from the open ground this day, to show how they will stand frost." The blooms were fresh, bright, and very little the worse for their exposure.

— SOME time ago we referred to the devastation effected in the DRUMLANRIG WOODS by a severe gale. It appears according to a northern contemporary that "The trees have remained ever since as they fell. No one could be induced to undertake the huge contract of removing them. Just lately, however, an enterprising London merchant has purchased the entire lot from the Duke's stewards, who, indeed, had become so anxious to have them removed that they offered them at an extremely low price. The purchaser has begun to do a flourishing trade, for he can afford to undersell the Baltic merchants. The incident seems to show that forestry is indeed a neglected industry in this country. There seems no reason why the Baltic trade should not be permanently rivalled by the products of our own woodlands."

— MR. GILBERT has sent as samples of THREE GOOD THINGS FROM BURGHLEY—namely, Her Ladyship's Favourite Melon, Burghley Champion Tomato, and the not yet extinct Chou de Burghley. As to the Melon, we have to regard her ladyship as an excellent judge. The fruit was beautifully netted, skin thin, flesh thick, colour deep green, and quality delicious. The Tomato is round, smooth, firm; the fruit looks good, and is as good as it looks. Chou de Burghley was in form like a well-grown Cos Lettuce, and all who tasted it wanted more.

— "T. W., *The Elms*," sends a note upon EXHIBITING GRAPES, in which he remarks that it is unfair working or single-handed gardeners should have to compete in the same classes with gardeners who are in charge of large establishments and have much greater facilities for producing good Grapes. He considers that a class should be set apart at large shows for "Working Gardeners," which would encourage more exhibitors to enter, and be much better than the present system.

— AN Irish correspondent writes as follows on BRITISH and FOREIGN APPLES:—"I am getting my neighbours at last to see that they must grow large fruit of the best quality to compete with the imported fruit, and not small rubbish like our markets are filled with this year. In Portadown last market day Apples were selling freely at £1 per ton."

— A LOVELY little annual is *IONOPSIDIUM ACAULE*, though little known and rarely seen, and if introduced again as a new plant would become popular. In the Whittington Nurseries at Lichfield there is a good breadth of it now in full beauty. It forms a carpet of lovely silvery grey close to the ground, and as it has a habit of reproducing itself so freely from seed, no one need fear losing it, as thousands of young plants are coming up about the bed from self-sown seeds. Such plants will give a charming spring display, whilst spring-sown seeds out of doors give a later bloom.

— LARGE YIELD OF POTATOES.—Mr. J. Rogers, The Gardens, Langton Hall, Spilsby, states that, "Last spring, with several other varieties, I obtained from Messrs. Daniels of Norwich 1 lb. of Imperator, and lifted 108½ lbs., six of the largest weighing 9½ lbs., the heaviest being 1 lb. 13 ozs. The seed was cut into eighteen sets, and only planted in the ordinary way in old garden soil resting on sand. The produce is quite free from disease, is not ugly grown, but mostly of regular shape, rather a long round."

— THE third and fourth "fascicules" of reports of the ANTWERP INTERNATIONAL BOTANICAL CONGRESS, held from the 1st to the 10th of August, are now issued. They continue the reports from page 225 to 420, and contain papers by M. L. de Nobile of Ghent, M. E. Laurent of Vilvorde, Dr. Jules Gandy of Ixelles, M. Amelin of Brussels, M. F. Bravenich of Ghent, M. J. H. Krelage of Haarlem, M. Emile Rodigas of Ghent, M. Adolphe d'Haene of Ghent, Dr. Henri van Heurck of Antwerp, M. C. Wittmack of Berlin, and M. O. Bruneel of Ghent. These deal with a variety of subjects, particular prominence being given to the Flora of the Congo.

— A SUBURBAN correspondent wishes to know if any of our readers can explain the undermentioned fact—"During the four past winters I have had two plants of *AGAVE AMERICANA VARIEGATA* out

of doors in my garden near London, and each season the frosts have destroyed the old leaves—that is, those of the previous year, the young leaves of the current year's production being uninjured. We are so accustomed to seeing the young growing tips of plants first injured by frost, that it seems strange the old leaves should, in the case of this *Agave*, be the only ones affected."

— "It could not be want of a subject," writes "C. S. R.," "that compelled Mr. Muir to so depreciate the *STEPHANOTIS* AND *GARDENIAS* (page 295). 'The pure colour and fragrance may be thought pleasing,' says he, 'but the fragrance of the *Gardenia* especially is so strong that not one person in a dozen can really enjoy it.' How different this sounds to my experience of *Gardenias* and persons, as not one in a hundred speaks but to praise. Are Mr. Muir's olfactory nerves so very acute that the fragrance of the *Gardenia* is offensive? If so he was right in transferring them to the rubbish heap, as no one would wish to hear that the able gardener at Margam Park had died 'in aromatic pain.' That these plants are subject to mealy bug I admit; but if clean to start with the attention that most other stove plants require to do them well will keep the *Gardenias* and *Stephanotis* clean. We find a regular application of weak soapsuds very useful for these plants."

— AN extensive WILLOW FARM IN GEORGIA is thus described by an American contemporary:—"A flying trip yesterday to the Osier Willow farm of I. C. Plant, a mile below the city of Macon, presented a surprise. In a building on the premises were a number of negro women and boys at work stripping the bark and leaves from the Willow switches. This is the first cutting of the crop of two years' growth, and the yield will be two or three tons. These switches are from 4 to 7 feet long, and are cut and placed in bundles like sheaves of Wheat. They are then taken to the stripping building and placed in a vat filled with water. The large ends are then placed in a peculiar little machine, which loosens the bark for a couple of inches. Passing along on the table they are placed one by one in the strippers, and with a pair of pliers are pulled through with one jerk. This process takes off all the bark and leaves. The switches are then wiped off with a woollen cloth by passing them through the hand. They are then bundled and laid away to dry. All the leaves and bark are dried and are used for a certain kind of medicine. Mr. Plant has 400,000 Willows now growing on his farm. He has within one week set out 80,000, and they are growing finely. He will have sixty acres in Willows alone. A ton to the acre is the average yield, and the Willows, when shipped dried, command 200 dollars per ton in a dozen markets. In three years all he has set out now will be high enough to cut."

— AT the annual Cryptogamic Meeting of the Essex Field Club on October 3rd, Mr. Worthington G. Smith read an amusing paper upon BOTANICAL MARE'S NESTS, in which several remarkable cases of "mistaken identity" are given. One of these, referring to the ear cockle in Wheat, was thus noted:—"I always take pleasure in thrusting at shady 'doctors' and 'professors.' I will, therefore, take a 'doctor' first, a German 'doctor.' His name is Dr. Carle Mücke, a peculiar name, in English it indicates a mess or a muddle. This Dr. Mücke, in 1870, discovered a terrific mare's nest in reference to a common and very familiar disease of Wheat termed 'ear-cockle.' 'Ear-cockle,' as every beginner knows, is caused by a minute thread-worm, named *Anguillula tritici*. This little worm, which is allied to the so-called 'vinegar-eel,' causes little offensive galls to replace grains of corn in the ear. Friend Mücke 'discovered' that the disease was caused by a mare's nest fungus, named by him 'Xenodochius,' he probably meant *Xenodochus*. Dr. Mücke's essay was published by the Board of Agriculture of Melbourne, and Dr. Mücke was awarded a substantial annual prize by the Board for his wonderful mare's nest. The essay is a remarkable one. The German 'doctor' does not write 'tritici' but in every instance where he should use that word, he writes the extraordinary word 'tritii'; he also tells the Melbourneites that some persons believe ear-cockle to be caused by the 'chrysalis of an aphid.' The 'chrysalis of an aphid' is a grand mare's nest, one of the first water. He illustrates what he calls the 'imagines'—possibly meaning imago—of an aphid without a rostrum. He also figures a very red garden worm, and calls it 'such an eel,' and says it is not always red, for, says he, it is sometimes white. Dr. Mücke says he has examined 'flour' from the roots of Wheat, and found the 'flour' to consist of the 'eggs of an aphid unknown to him.' Fancy 'flour' from the 'roots of Wheat' being not flour but the eggs of an aphid, and an unknown aphid!"

— IN another portion of the paper occurred some observations upon DODDER AND RAFFLESIA as follows:—"In 1873 a trial took place at Bedford for 'breach of warranty.' A farmer had bought Clover seed infested with Dodder seed, the result, of course, being that all the farmer's Clover was destroyed by the parasite. The farmer claimed £202 10s. damages. In defence, great doubts were thrown on the very existence of such dubious and impossible things as Dodder seeds, and it was said in the defence that 'Dodder is a parasite, the propagation of which is wholly unaccountable to the most experienced agriculturists.' Judge and jury were alike perplexed. Although the very existence of such things as Dodder seeds had been tabooed, the jury found the defendant guilty, but assessed the damages not at £202 10s. but £50. The Judge evidently believed in the non-existence of Dodder seeds, and the unaccountable mystery of Dodder, for he gave the defendant leave to have the damages reduced to £6 7s. 6d., the price paid for the seed. Before dismissing Dodder, I will mention a little mare's nest discovered by a writer who described the well-known plant named Rafflesia in the *Edinburgh Review* for October, 1883. The Rafflesia, as is well known, has a similar parasitic habit with Dodder. The reviewer said 'the Rafflesia is a plant or fungus,' observe that! 'a plant or fungus.' The mare's nester elsewhere in his description says 'that fungi are commonly regarded as not bearing flowers;' the Rafflesia fungus was, of course, an exception to this rule."

— IT is estimated that the FRUIT YIELD between Kingston and Newburgh in the Hudson River district in America will exceed by 33 per cent. that of former years. The shipments of Grapes will reach about 5250 tons, valued at 367,500 dollars.

— ONE of the most interesting features of the CRANBERRY MARSHES OF WISCONSIN are the pumps used to flood the ground. On one marsh there are two that draw their supply from the Fox River, and throw 80,000 gallons a minute. The stream is 20 feet wide, 4 deep, and moves at the rate of 160 feet a minute, flooding the 1000-acre marsh to a depth of 12 to 15 inches in ten hours. The water is depended on as a protection against frost, also to drown the insects which infest the Cranberry blossoms in May.

— THE annual conference of the CRYPTOGAMIC SOCIETY OF SCOTLAND was recently held at Corrie, Island of Arran. The weather was unfavourable throughout, and fungi were not abundant. Ferns are plentiful in the island. *Trichomanes radicans*, *Hymenophyllum tunbridgense*, and *H. unilaterale* are found in abundance. Our esteemed correspondent, Dr. Landsborough, has on several occasions sent us notes illustrating the remarkably mild climate of Arran, and in confirmation of these it may be added that Palms, Camellias, Myrtles, Heaths, Fuchsias, &c., have been grown in the open air uninjured through a long succession of winters. At the business meeting of the Society, Dr. Flaxman Spurrell in the chair, it was resolved to publish a volume of Transactions after the next annual conference, which will take place at Aberdeen in the autumn of next year, under the presidency of Professor J. W. H. Trail.

— THE Royal Caledonian Horticultural Society will hold a SPECIAL EXHIBITION AND CONFERENCE ON APPLES AND PEARS in connection with the Society's Winter Show in the Waverley Market, Edinburgh, on the 25th and 26th November. While collections of Apples and Pears are solicited from all parts for comparison and instruction, the chief object of the Conference is to utilise the favourable opportunity presented by the fine crop this year, for the purpose of gaining information about the Apples, and Pears grown in Scotland, comparing their merits and correcting their nomenclature. All fruit-growers, especially in Scotland, are therefore invited to send as complete collections as possible of the Apples and Pears grown in their district; and as the object is solely educational, there will be no competition and no prizes. It is not necessary that the fruit should be grown by the sender. Intending exhibitors must give notice to the Secretary or Assistant Secretary in writing not later than Monday, the 16th November, stating the number of varieties to be exhibited and the amount of space that will be required. Collections of fruit may be consigned to Mr. William Young, Assistant Secretary, 18, Waverley Market, Edinburgh, and delivered there on or before Friday, 20th November. The Council will pay the carriage of fruit and take all possible care of it, and will also see that it is properly staged for the inspection of the Committee; but they will not be held responsible for any error, damage, or loss of any fruit consigned to them.

— A MEETING of the BELGIAN HORTICULTURISTS was held on October 12th at Ghent, when there were present MM. le Cte. de Kerchove de Denterghem, Fr. Desbois, V. Cuvelier, L. Desmet, Edm. Vervaeet, Ad. Rosseel, Ch. Van Geert, M. Ch. Spaë, and Romain Desmet. Certificates were awarded for the following:—*Cypripedium Fairieanum*, from M. Jules Heye-Leysen; *Dendrobium* species, from MM. Vervaeet et Cie.; and *Eucharis Sanderiana*, from M. Desmet-Duvivier. Honourable mention was accorded to *Comporetia macroplectron*, from MM. Vervaeet et Cie.; *Cypripedium Arthurianum*, from M. Ed. Pynaert; and *Cattleya superba splendens*, from M. Desmet-Duvivier. Cultural commendations being awarded to *Cocos Blumenavi*, from M. L. Spaë-Van der Meulen; and *Tillandsia musaica*, from M. Bernard Spac.

— THE first meeting of the Floral Committee of the NATIONAL CHRYSANTHEMUM SOCIETY was held yesterday (Wednesday) at the Westminster Aquarium, the President, Mr. E. Sanderson, in the chair. There was a good attendance, and several exhibitors contributed blooms of new Chrysanthemums and other plants. Messrs. J. Laing & Co. had some fine blooms of Mrs. Cannell, a Japanese of lighter colour than Brise du Matin, L'Ile des Plaisirs, and some handsome Tuberous Begonias. Mr. N. Davis, Camberwell, had some good blooms; Mandarin, a rosy lilac Japanese of great promise, being certificated; also Lackne, a dwarf ree-flowering Japanese, orange bronze in colour, and Mrs. Cullingford, a fine early-flowering white Pompon, being commended. Mr. John Forbes had a certificate for Brise du Matin, a beautiful Japanese variety with fluted florets, of a delicate pale pink colour. Good blooms of L'Ile des Plaisirs, Margot, and M. Mousillac, were also staged. Mr. E. Boyce, Mr. T. S. Ware, and Mr. G. Stevens also showed collections of blooms, and Messrs. H. Cannell & Sons, Swanley, contributed stands of Tuberous Begonias and other flowers.

— A CORRESPONDENT favours us with the following:—"The seventh ordinary meeting of the SCOTTISH HORTICULTURAL ASSOCIATION was held in the Bible Society's Rooms, St. Andrew Square, Edinburgh, on the 6th inst. Mr. Lindsay presided. Dr. J. M. Macfarlane of the Royal Botanic Garden, Edinburgh, gave a paper on 'Nepenthes,' in which he drew attention to the history; general structure, affinities, microscopic structure, and physiological action, species, and cultivation of this curious class of plants. He stated that about forty species are known, of which about twenty have been introduced during the last thirty years. He pointed out the arrangement by which insects are caught in the pitchers of the plant and digested, and drew attention to the very remarkable peculiarities in the species which have been introduced, as well as in those that are still known only in dried specimens. A discussion followed, during which the Chairman stated that the first seedling *Nepenthes* raised in Scotland was reared by Mr. Kelly of Messrs. Dickson & Sons' Nursery, Edinburgh, about forty years ago. Mr. Burbidge of Trinity College Botanic Garden, Dublin, gave the result of some of his observations in Borneo, the principal habitat of Pitcher Plants. Various exhibits of new varieties of fruits and flowers were shown, as well as a fruit new to Europe—the *Aberia Caffra*—ripened at La Martolo, Italy, and likely to be a serviceable half-hardy fruit, suitable for cultivation in Peach houses in this country. It is a native of Africa, and belongs to the order Bixaceæ. The fruits of this *Aberia* or 'Kei Apple' resemble Green Gage Plums in shape and size, being of a soft yellow colour and of an agreeable subacid flavour, to which a little sugar is an advantage." The fruit referred to as being "new to Europe" was grown and ripened at Dangstein for years, and is still grown by Lady Dorothy Nevill in a span-roofed conservatory at her residence in Sussex.

NOTES AT MESSRS. J. VEITCH & SONS' NURSERY.

LAPAGERIAS.

LAPAGERIAS are general favourites now, and their culture is fast extending as their value is becoming better known and their peculiarities mastered. For cool houses they are especially useful, and when once well established the charming wax-like flowers are produced in great numbers. An admirable example of this is shown in the corridor of Messrs. J. Veitch & Sons' nursery at Chelsea, the roof of which is draped over its whole length with pendant wreaths of rose and white flowers that have a beautiful appearance when viewed from either end of the building. The shoots which hang free from the roof are about a yard in length, and each bears a dozen or more large flowers, the bell-like form of which is so much seen from below than in any other way. It may be readily imagined that so beautiful an introduction to the nursery causes many inquiries for young plants of Lapagerias, and such inquirers are shown a house of healthy young specimens in the right condition for planting out

or for growing on as specimens in pots. The great point in the successful culture of these is to encourage a vigorous growth, never to allow them to get into a stunted or weakly habit, and to keep them free from all insect pests. Soil is not of so much importance as some might suppose, for we have seen vigorous and freely flowering *Lapagerias* in many composts from charcoal to pure loam.

GREENHOUSE RHODODENDRONS.

The Chelsea nursery has long been the especial home of introduced and home-raised *Rhododendrons* of the group known as greenhouse varieties, and nothing has done so much to popularise these useful as the numerous hybrids which have been obtained by this firm. The term "greenhouse," as applied to them is, however, misleading, for they require a rather warmer temperature than usually provided in such structures, though whilst in flower they will stand in a cool house very well. At other times a temperature intermediate between a stove and a greenhouse is the best for them. The old *Taylori* is still a favourite, and deservedly so, for it produces its trusses of bright pink flowers most freely and continuously. *Queen Victoria*, with buff flowers; *Duchess of Edinburgh*, buff; *Maiden's Blush*, a delicate rose-tinted form, and the species *R. javanicum* are all flowering well, and are more or less known in collections. A house filled with these and other varieties is very attractive now, but it is in another house where the more recent and greatly improved hybrids are found. Amongst the hundreds of seedlings that have been raised from careful well-considered crosses, some are constantly flowering, and varieties with scarlet, rose, bluish, yellow, buff, and white flowers of great merit are noted every week. Those showing strongly marked characteristics receive names, and the others are consigned to the rubbish heap. Fortunately, however, there are not many that have to be cast out in this way, and fresh shades of colour are constantly being obtained, together with increased substance of flower. A series of double forms are being secured, and a grand addition has recently been made to these in a white-flowered variety named *R. balsamiflorum album*, which has beautifully formed blooms much like a *Tuberose*, and as pure as a white *Camellia*. Rose and yellow varieties of *R. balsamiflorum* named respectively have already been raised, so that there is now a trio of double varieties that will become great favourites, the flowers being particularly well suited for buttonholes or bouquets.

BOUVARDIAS.

As flower-yielding plants *Bouvardias* have become of the utmost importance in gardens, and they furnish most welcome supplies of bright or delicately tinted blooms, the value of which cannot be over-estimated for bouquets and floral decorations generally. One house at Chelsea has now been gay for some weeks, and will continue so for a long time, with a choice collection of the best varieties, amongst which the following are very notable:—*Priory Beauty*, one of the finest varieties in cultivation, very strong in habit, most floriferous, bearing compact trusses of charming soft pink flowers. In every respect this is a grand variety, and though as yet but little known it will soon take a foremost place in gardens where these plants receive special attention. *Reine des Roses* is also a free and pretty rose-coloured variety; *Dazzler* is bright rosy scarlet, good habit, and free-flowering; *rosea oculata* is distinct, the tube rose-tinted, the lobes white; *Vreelandi* and *umbellata alba* are the best whites, both free and with substantial flowers; *Hogarth* and *elegans*, scarlet; *umbellata carnea*, soft pink; *Humboldtii corymbiflora*, white, long handsome flowers; and *longiflora flammea*, scarlet, are all good single varieties, while of the doubles *Alfred Neuner* still holds its own, producing the best formed flowers.

WINTER-FLOWERING CARNATIONS.

These form another series of useful plants for autumn and winter, and a house is devoted to a collection of the most effective varieties. One that is especially worthy of notice is *Mrs. Keen*, which has dark maroon highly fragrant flowers, produced in great numbers. It is also of such a tall strong-growing habit that it is admirably adapted for training to the roof of greenhouse or conservatory, and in such a position affords an almost perpetual supply of flowers. For training as a specimen on a globular or other formed trellis it is also well suited; but the first-named method is much the better. A few only of the leading varieties can be named, and all are so beautiful that it is difficult to make a selection. *Lucifer*, scarlet, free; *Princess Stephanie*, bluish white; *Pride of Penhurst*, yellow, perhaps the best of its colour, certainly very free and with fine blooms; *Juliette*, rosy purple; *Van Houttei*, scarlet; *Sir Evelyn Wood*, rich crimson purple, a fine shade of colour, and most handsome variety; *Phoenix*, dark crimson; *Alexandre Regnier*, yellow; *Sir Charles Wilson*, cerise, the flowers very full, and with cut edges; *Andalusia*, yellow, very floriferous; *Lady Macheth*, delicate pink; *Whipper-in*, scarlet, streaked with maroon; *L'Hermine*, white; *M. Jacotot*, white, flaked with pink; *Ruby*, violet purple; and *Lord Roakey*, scarlet. Those named have been selected chiefly for their floriferous qualities, which can be fully appreciated where large quantities of flowers are in demand.

IXORAS.

A house of *Ixoras* cannot be seen in every garden, and only in few nurseries, yet they are handsome plants when well grown, and their compact globular trusses of brightly coloured flowers are very beautiful amongst other stove flowering or foliage plants. The old *Ixora coccinea* is still among the best in brightness of hue, and it is moreover of good habit. Another form now flowering at Chelsea is *I. Burbidgei*, which is regarded as an improved variety of *I. salicifolia*, the leaves similarly long and tapering, but it is of stronger habit, the flowers rich orange-

red in fine trusses. *I. Williamsi* is also of fine colour, while *I. odorata* is remarkable for the great size of the white or bluish-coloured trusses, which sometimes exceed 9 inches in diameter. *I. Westi* is of the same type, with broad handsome leaves and huge trusses of delicate rose-tinted flowers. In the same house some plants of *Ipomoea Thompsoni* trained to the rafters are showing blooms abundantly, and will shortly afford grand display. *Batatas paniculata* is grown with the above, and flowers freely, though they do not last very long.

PITCHER PLANTS.

Wonderful as have been the displays of these plants in previous years, they are still finer this season, and the houses devoted to them present a most extraordinary sight. Hundreds of variously formed and diversely coloured pitchers are hanging from the gigantic *Nepenthes Rajah*, the grandly coloured *N. Northiana*, and the peculiar *N. bicalcarata* to the diminutive *N. ampullaria*, *N. Morgania*, *N. intermedia*, *N. Hookeri*, *N. Rafflesii*, *N. cincta*, and many others attract attention in turn, but one of the best in colour and freedom of "pitchering" is *N. Mastersiana*, of which there is a grand stock. Of this superb *Nepenthes* there are numbers of plants in baskets 8 inches square, bearing twenty-five to thirty pitchers of a deep rich red colour, and clustering closely around the baskets. The plants alone are well worth a visit, and a better time than the present could not be chosen.

There are numberless other attractions at Chelsea just now; for instance, the great collection of Orchids always contains something good in flower. Then there are the miscellaneous stove and greenhouse plants, amongst the former being the magnificent *Anthuriums*, and of the latter the *Heaths* and the newly imported *Azaleas* are in superb condition. Preparations are also being made for the annual exhibition of *Chrysanthemums*, of which a large collection is grown, and in a few weeks' time they will furnish an additional feature.

POTATOES FROM SEED.

I KNOW nothing more interesting to the amateur than raising new varieties of Potatoes from the seed, for the results are so varied and surprising. This year I raised numerous seedlings from *American Purple*, and as they grew it was wonderful to observe how distinct the foliage of each was. Although fifty per cent. of the seedlings turned out to be blue the haulm of each one was different in some respect from the others. The shades of blue were varied also, and whilst one seedling was of an exceptionally light blue colour another was so very dark, so near approaching black, that I have called it "Niger." In addition to the blues there were pink kidneys, pink rounds, a bright magenta round and kidney, white rounds and white kidneys, and a flesh-coloured round. The haulm varied from 2 feet high to only 6 inches, and the tubers from the size of marbles to that of a cricket ball. I have selected fifteen of the most promising, and trust next year that I may be able to select at any rate half a dozen out of these, and no doubt the year after I shall be able to settle whether they are all worthless, or perchance one or more of good quality and constitution.

It may interest some of those who have never raised seedling Potatoes to know how I went about it. Last year I picked a few seed balls and hung them up to dry till this spring, when I broke them into pieces and planted the seed in boxes, which I placed in my Melon frame. When 2 inches high I moved them into a cool frame, and gradually hardened them off. In May I dibbed them out in a bed and kept them clean, moulding them up when they grew strong, and raising them a few days ago. The trouble is but little, and I consider that they are well worth a little time and care.—H. S. EASTY.

FOSTER'S SEEDLING GRAPE CRACKING.

"J. W., *The Elm*," puts his case very clearly as a questioner, then gives himself the answer. Let me give him my thoughts by way of suggestions. First I will take the situation of the house in which we will say this Vine is planted. Of course, we will take it for granted that the vineyard faces the south. Now comes the question, Is the Vine at either end or middle of the house? Say it is at the south-east corner, and this a shady one, so that when the sun gets to a certain height it is on it all at once, with the result that cracking takes place at once, simply by the steaming of the berries. To avoid this leave ventilation on all night at the front for this particular Vine, and increase it early in the morning. I have no hesitation in saying much better results are or would be obtained by having the Vine either in the middle of the house or even at the south-west-end. Opening the door or doors with increase of bright sun in changeable weather will materially reduce cracking. Heavy cropping of itself is a check to cracking, but then if fed by stimulants it is commenced at once. Starting the house with fire late just when the buds are showing signs of pushing and thus ripening late, no cracking will appear. Many plants in a vineyard is a fruitful source of evil, and certainly contribute to cracking. If Vine roots are outside the mulching is generally removed at midsummer, thus exposing the border to the drying influence of wind and sun; and if roots are near the surface, as they should be, they suffer, and when rain occurs there is another help to cracking.

Foster's Seedling is not generally a cracking Grape, certainly not with

me, but my border is inside. I have now cut my crop, and the berries were all sound. I have had a few good gardeners to see me just lately, and I also have had several visits to gardens, but have heard no complaint of Foster's Seedling cracking in West Norfolk. Old berries have done so, but then the cause is known, and is soon removed. It may be asked, Why does this crack in a mixed house more than the black? My answer is, The skin of Foster's Seedling is very fine, so transparent that the stones can be seen and almost counted. Prevent steaming or dew on the berries and there will be no cracking. Foster's Seedling is a very sure cropper, hanging fairly well, but I prefer Buckland Sweetwater on account of its larger berries, better richer colour, and the latter makes by far the best market Grape. Foster's Seedling looks too much like imported Grapes when cut for a few days.

"Thinker" puts a finish on the cracking or splitting of Grapes, and in my idea he is right. I have now two good Vines of Madresfield Court in full crop, and not the least signs of cracking. I have come to the conclusion that as my Vines are at least a month later than last year, in fact, not yet ready for table, I have missed the steaming time. I was fairly successful last year, but at the beginning of September in hot days, notably after a wet or dull morning, although ventilated, yet the house would steam. To avoid this I set the two front ventilators so that they were always open, and kept the foliage fairly free at the top, so that the damp should find its way out. I have not the fine colour this time, but if they will keep till Christmas a point will be gained.—STEPHEN CASTLE, *West Lynn*.

NOSTELL PRIORY.

A SHORT time ago the members of the Yorkshire Association of Horticultural Societies visited this fine old residence of Lord St. Oswald, and the following historical notes have been obligingly furnished by Mr. Herbert Chapman, the Secretary of the Paxton Society, Wakefield, the description of the grounds and gardens being supplied by Mr. W. K. Woodcock, who attended as the representative of one of the Sheffield horticultural societies.

The following history of Nostell or Nostel Priory is taken from Banks' "Walks About Wakefield":—"We come to Nostel, a seat of the Winns, whose fine mansion in the park bears the name of Nostel Priory. The modern house is partly seen from the high road as we cross the elegant bridge that spans the large lake belonging to the grounds. The water lies on each side of the Wakefield and Doncaster turnpike road, and is about forty acres in extent. It consists of an upper, middle, and lower lake, measuring in length three-quarters of a mile. The overflow goes into the River Went. The present Nostel mansion was built in the early half of last century near the site of the Priory, which, having been adapted to the purposes of a private family, was to that time the residence of the owners of the estate. The eastern front looks down an avenue of trees, wholly or chiefly Elms, nearly a mile long, though less than half that distance lies within the limits of the park, the rest being continued across lands beyond the wall. The park, which is said to contain 250 acres of land, is well wooded and stocked with fallow deer.

The church stands within the park, and an inscription in the vestry states that Mr. Winn repaired it. It contains several monuments of the Winn family. The north chancel ceiling is ornamented by King Oswald's three crowns, a lion between three pheons, and other emblems. The priory of St. Oswald at Nostel was founded by Robert de Laci, the Norman baron, son of Ilbert de Laci, the well-known first Norman lord of the castle and honour of Pomfret. The name of Oswald, king and martyr, was held in great esteem in this part of Yorkshire, coming as he did after King Edwin's death at Hatfield, and re-establishing the kingdom of Northumbria. The monastery thus founded was for canons regular of the order of St. Austin. The site of the old monastery is said to have been where the church stands, the new priory of St. Oswald being erected a little north-westward of that and nearer the lake. The priory came to an end at the general dissolution of monasteries.

In 1654 Mr. Rowland Winn, a London merchant, purchased the estate and sold it the same year to his brother, George Winn, Esq., who became a baronet in 1660. The present house was built by the fourth baronet, Sir Rowland Winn, who died in 1765. The estate has descended from him to the present possessor, the recently ennobled Lord St. Oswald.

The gardens and pleasure grounds, which is the part of most interest to readers of this Journal, are large and are throughout in most admirable keeping, reflecting the highest credit upon the good management of the head gardener, Mr. Deavan.

The fruit and kitchen gardens are situated at a considerable distance from the mansion and near the principal entrance to the park. Immediately outside the garden walls is a very fine newly erected range of shedding for poultry, with large asphalted yards, in the which is kept a choice collection of various kinds. Inside the walls are a series of nearly new low brick pits heated by hot-water pipes and well stocked with useful plants for winter flowering, principal amongst which are Gardenias, Tuberoses, Bouvardias, and Primulas. The first-named are clean, strong bushy plants well set with buds from cuttings struck in February. Some late Tuberoses are throwing up strong flower spikes in the same pit with Gardenias; these being favourites with her ladyship, are grown in large quantities all through the season. Bouvardias also are grown by hundreds, principally for supplying flowers. The stock of Primulas is a fine one, a large number of plants being grown, all large, strong, and healthy, promising well to bear abundant blooms.

We next come to two well-built span-roofed ranges of glass erect about three years since. The first range is devoted to plants, and consists

of a greenhouse 32 by 18 feet, and a plant stove 60 by 18 feet. In each house there is a central bed or stage and side stages with a path round. The greenhouse was at the time of our visit very gay with large numbers of well-grown dwarf specimens of Zonal Pelargoniums profusely bloomed and making a blaze of colour. Most noticeable in the plant stove are the large bushes of Gardenias occupying the greater portion of the central bed. These bushes are about 5 feet through each way, are planted on low conical mounds in the centre of the pit, and are in vigorous health, bristling with bloom buds in all stages of development. The leaves are large, of a bright glossy green, without a speck of dirt apparent anywhere, and so free from mealy bug that Mr. Deavan told us he dare venture to make an offer of one guinea for each one that could be found. The treatment they had received was very simple. They were all lifted and replanted, disturbing the roots as little as possible, in February, the compost being about equal parts of fibrous peat and good turfy loam with a plentiful admixture of broken charcoal and rough grit sand. The drainage is good and the supply of water liberal. They are occasionally watered over the foliage and at the roots with clear soot water.

Whenever mealy bug or scale is seen the plants are at once syringed thoroughly with petroleum at the rate of a wineglass to a gallon of water, which Mr. Deavan thinks the best of all insecticides. His mode of applying it is by having two men each with a syringe, one discharging it vigorously into the pail, and so keeping the water violently agitated, whilst the other distributes it over the plants. Throughout the month of May flowers were cut from these fine bushes at the rate of 250 per day. Trained on the roof of this stove are large and strong Allamandas and Stephanotis, the latter still carrying plenty of fresh flowers, and the foliage as clean as that of the Gardenias underneath, maintained so by the free use of the same insecticide.

The second range consists of two vineries each 40 by 24 feet. The first of these is planted principally with Vines of Black Hamburgh, which have this season finished a fine crop, the greater portion of which had been gathered; but there are still hanging some fine well-shouldered bunches of about 4 lbs. weight each. In the late house a fine crop of fruit is finishing superbly, the varieties being Alicante, Lady Downe's Seedling, Madresfield Court, Gros Colman, and Gros Maroc. The latter is in appearance the finest Grape in the house, and is there considered to be the finest late Grape in cultivation, destined eventually to drive Gros Colman out of the market, owing to its superiority in appearance and flavour. Complaints are often made as to its being a shy setter. As a remedy against this they are impregnated when in flower with pollen taken from Black Hamburgs flowering at the same time in another house, the result being "a set" as good as could be obtained from the latter variety. In this late vinery the Vines are planted 5 feet apart up each side the house, meeting over the central path, and between each two rods a single stem of Tomatoes is trained in the same way, and carrying plenty of good fruit. In the early vinery was a grand pyramidal plant in pot of Rhododendron Gibsoni, 7 feet high and 5 through at the base, well furnished throughout and set with buds at every point; also several Azaleas similar in size and appearance.

Leaving these houses, we were conducted first through a lean-to Pine stove, in which a number of medium-sized useful fruit, principally Black Jamaica, were maturing. Over the pathway, along the back of the Pine pit, a number of plants of Hibiscus and Dipladenias were flowering profusely, and next, through an ancient range of four houses, consisting of three vineries and a plant house, heated by flues and built 120 years ago. The outside timbers of these houses are almost devoid of paint, as they have long been condemned to be taken down, but still they are apparently sound and much more fitted to withstand a gale than many modern houses only recently erected. At the back of this range, running the entire length, is the Mushroom house and potting sheds of the same date. In these we were shown a Mushroom bed spawned on the 22nd of August, and now showing Mushrooms in plenty.

There is a splendid range of comparatively newly erected lean-to Peach houses, facing south, 212 feet long by 12 feet wide, divided into four houses each 53 feet in length. The back wall is covered throughout the range with large and very healthy trees of Peaches and Nectarines, from which fruit had been gathered continuously since the first week in June. Some fine fruits of Bellegarde and Walburton Admirable were still hanging. The front of each house is furnished with a low curved wire trellis, which in the first house is covered by healthy plants of Gloire de Dijon Rose, producing flowers in quantity. In the second it is occupied by Peach trees, in the third by Figs, and in the fourth by Peaches. It is found, however, in the case of the third house, that Figs and Peaches do not work well together in the same house, the heat required for maturing the late Figs being injurious to the Peaches. It is intended, therefore, shortly to remove the latter, and to convert the house into one for Figs alone. In this house were some large specimens of Tritonia anrea, the head of bloom on each plant being about 2 feet through. The colour was bright, and as thus grown would be very effective in the most choice collection of autumn-flowering plants.

Near this range is an ancient flued wall for fruit trees. This is supposed to be about 200 years old. The flues are not now used, but have been so up till a recent date. It runs north and south, dividing the kitchen gardens into two parts, the total extent of which is four acres, besides two acres of orchard, the greater portion cropped with vegetables between the rows of fruit trees.

In the second part of the kitchen garden is a broad border running the entire length of the garden (150 yards) well filled with bedding plants for cutting purposes, and separated from the vegetable garden by a strong wire fence covered with Gloire de Dijon Roses in fine condition. At one

end of this border is a beautiful specimen of the Maidenhair Tree (*Salisburia adiantifolia*). It is about 30 feet high and a perfect pyramid in outline. Adjoining this garden is a small lawn containing a number of Rose beds, both standards and dwarfs, clean and vigorous, also flanked at each corner by two magnificent specimens of Drooping Ash, the largest we have seen. On the south side of this garden is the riding school and conservatory, occupied principally by large and healthy Camellias and fine pyramid Azaleas, each about 7 feet high by 5 feet in diameter. In this house also, as in the Peach houses previously described, we noticed a great number of pyramidal specimens, about 3 feet in height, of scented Pelargoniums. Lady St. Oswald takes great interest in these, and esteems them amongst her choicest favourites, consequently by her wish a great many are cultivated, including amongst them every known variety.

From the carriage drive into the park past the east front of the mansion we have a fine view of a noble avenue of English Elms about one mile in length, the trees all of great size and beauty. About 300 head of deer are kept in this park; numbers of them are visible in the

J. Hall, 26, Westgate, Wakefield, from whom many other beautiful views of Nostell may be obtained.

GRAPES AND GRAPE JUDGING.

I HAVE always entertained a certain amount of respect for "A Kitchen Gardener's" writings, believing him to be an experienced and practical gardener, but when I read such statements as those on page 293 we almost begin to wonder if he really is in earnest or not. He even disputes the superiority of Madresfield Court over Alicante, and this simply on the ground of the popularity of the latter. How this proves the case is a mystery. He asks, "Has his (meaning Mr. Iggulden's) Madresfield Court or any other of his summer Grapes been passed once this season in favour of later varieties?" Did not Mr. Iggulden quote particularly the case at the late Taunton Show, where, if I mistake not, two lots of Alicantes were placed before good Madresfield Court? Just let "A Kitchen Gardener" imagine himself the exhibitor of the latter, especially

FIG. 53.—NOSTELL PRIORY.

avenue, and add much to the picturesque effect. The woods surrounding the lakes contain fine collections of hybrid Rhododendrons, which are a grand picture in May and June. A charming view of a portion of the west front of the mansion is obtained from the middle lake. There is also a beautiful miniature garden called the menagerie gardens, from the fact that at one time a collection of wild animals was kept. This garden is formed in the bed of what has been an ancient stone quarry, and the boundary walls of which are the natural red sandstone formation as left in quarrying. Upon these walls British Ferns, principally *Athyrium*s, are growing in quantity, and find a congenial home. Some very fine examples of *Lilium auratum* are flowering in this sheltered garden, having occupied their present position about three years. In this garden is a very ancient and romantic cottage, which was once the gardener's cottage, but is now unoccupied. In front of this cottage is a fine old tree of the Snowy Mespilus.

Having now concluded our tour of the gardens and pleasure grounds, we have to record our thanks to Lord St. Oswald for the pleasure he has thus afforded ourselves and our large party, and to Mr. Deavan, his able gardener, for the interest he imparted to our visit to Nostell by his courtesy and solicitude to afford all the information in his power.

The view is engraved from a photograph furnished by Messrs. G. and

if he had taken more than ordinary pains to produce it in good condition as probably the exhibitor in this case had done. How would he have taken it. Not in very good grace, I fear.

But after all this does not strike the root of the question. I maintain that judges by following such a course as the one quoted, whether consciously or not, are promoting evil by encouraging gardeners to cut Grapes in August and September which certainly ought not to be cut for months later. Who, I should like to know, would grow Alicantes and Gros Colman to be used in the months named? and this season I saw the latter exhibited in July in the north of England. By all means let the cultivation of Madresfield Court be encouraged, and we shall then in a comparatively short time see whether it is not a "standard" Grape (not for keeping, no one claims that for it) or not. I do not exactly say it will become a standard variety, but I do venture to predict that when its cultivation is better understood, as it certainly is rapidly becoming, that it will occupy a conspicuous place in every Grape-growing establishment of any pretensions.

Everyone who has been interested in this Grape, and who has read the reports of shows published in the Journal, must have noticed how increasingly popular it has become the last year or so, and can we wonder at it? for what other black Grape have we to compare with it for summer

and autumn use? I maintain that the Black Hamburg itself cannot compete with it for flavour nor appearance either when well grown. Muscat Hamburg may be as good in point of flavour, but will not compare in berry or colour. If "A Kitchen Gardener" had seen the grand bunch of Madresfield Court exhibited last month at Dundee, and again at Edinburgh, I fancy he would hesitate before pointing out the bad points, which he did on page 293, for certainly in the splendid examples referred to none of these bad points were to be seen. It reflected the highest credit upon the grower, whose name I unfortunately cannot now remember. I shall never forget the splendid examples of this Grape that used to be seen at Cardiff a few years ago from the gardens of Cyfarthfa Castle. It was these examples of cultural skill that first prompted me to endeavour to overcome the difficulties attending the culture of this grand Grape, and if I have not succeeded yet I feel encouraged by what have been obtained, and shall certainly persevere still further in spite of all "A Kitchen Gardener" may have to say against it.—WM. JENKINS.

I AM glad to find that this subject is receiving the attention it merits and am convinced the outcome of it will be that judges next season will not so readily accord first honours to unripe fruit. According to the views of "S." (page 268), who argues cleverly, and carefully avoids answering important questions put to him, if we discourage the exhibiting of late sorts of Grapes at our early shows, then we inflict great hardships, and what is worse, as being of more general interest, we exclude all our finest sorts, and these will never be shown in perfection. A very few years ago this argument would have had some weight, but is now simply sentimental and worthless. Is it possible he has overlooked the fact that Chrysanthemum shows are now held in nearly every town and village of any importance, through the south and south-western counties at any rate, and that in every case prizes, and in some instances good ones too, are offered for Grapes? It is then when these magnificent examples of late Grapes should be seen to advantage, and receive the honours rightly deserved, but to encourage the general forcing of these so as to have them coloured early—I will not say ripened, for ripe they are not—is a very different matter, and I am surprised to find that there are practical disinterested men advocating it.

I think it will generally be conceded that not one of these showy late Grapes, if we except Mrs. Pince, which under good treatment is much better in quality than the majority, are of first-rate quality, and some of them at their best only second-rate, yet they are, if we may believe "A Kitchen Gardener," to gradually oust out such sorts of Madresfield Court, and doubtless Black Hamburg, one being fully equal to the other taking all things into consideration, and both require about the same amount of skill to bring them to perfection. Black Alicante in particular is considered worthy of every encouragement, and to be the Grape of the future, and why? Simply because, according to his ideas, it is the most easily grown of all Grapes, never failing to set and colour well, and keeping sound and in splendid condition for months, "while its value on the table may be reckoned from the quantity grown everywhere and the great demand for it in the market." The latter qualification completely spoils the whole of "A Kitchen Gardener's" rather overdrawn estimate, and he would have done better to have boldly stated that the quality was all that could be desired, or something to match what he had previously advanced. This correspondent really contrives to refute his own arguments, his zeal evidently overruling his discretion. For instance, he expresses the opinion, and which it will not serve my turn to dispute, that varieties "which are in the habit of winning prizes, are soon sought after and planted by the public generally," the natural consequence being that showy Grapes, unless intelligently judged, as they certainly were not at Shrewsbury and other shows I have previously mentioned, will gradually oust out sorts that require more skill in culture perhaps, but which are infinitely superior as far as quality is concerned, and that, after all, ought to be the primary test. I would like to call the attention of "S." to this passage, which I quoted from "A Kitchen Gardener's" letter, and would ask him whether a better reason could be given why these second-rate and admittedly easily grown sorts should be excluded from the early shows, or at any rate from classes where they would have the better varieties at a decided disadvantage.

Then as to the other proof of quality, as shown by the great demand for it in the markets. Evidently "A Kitchen Gardener" knows but little about the class of fruit that rules the market, or, if he does, I do not. According to my experience, appearance has more to do with a ready sale than quality, the latter being quite a secondary consideration. Again, how many employers would eat the best ripened Alicantes placed before them if they could have the choice of only moderately well-grown Black Hamburg, Muscat Hamburg, or Madresfield Court? May I ask, Does the noble marquis alluded to have those Alicantes regularly sent to the table after, say, the Black Hamburgs are finished? or is it not rather nearer the mark to say that the majority of those handsome and doubtless well-ripened Alicantes find their way into the markets? Otherwise I shall have but a poor opinion of this nobleman's taste, for the simple reason that I never tasted Alicantes to equal either Hamburgs or Madresfield Court. The latter is by no means so difficult to grow as some people seem to imagine, but it certainly requires more skill to bring it to perfection than does the Alicante. Madresfield Court is, as a rule, quite as well coloured as the majority of the bunches of Black Hamburg, keeps better than that variety, and may safely be said to better please the palate of some connoisseurs. With us it keeps plump and good till late in October, and by that time the Alicante is fit for the table.

We give Alicantes plenty of fire heat, and so must others if they wish

to have it in a presentable condition, or for eating either early or late in the season, and that is why I maintain it is not an amateur's Grape. It is highly satisfactory, no doubt, to win a prize with one of those easily coloured sorts, but when the excitement attending this achievement has subsided, or say when the Grapes, either those sent for the show or those left on the Vine, come to be eaten, it may be found that even their own Grapes may be sour.

"A Kitchen Gardener" asks if my "Madresfield Court, or any other of my summer Grapes has been passed once this season in favour of later varieties." I fail to see how my answer could possibly affect the argument we are holding, but at the same time must answer in the negative. Last season, however, I was very badly treated in that respect, and instead of being third with Madresfield Court in a class "for any other black variety," ought, in the opinion of one of the most successful gardeners of the day, as well as nearly every Grape-grower present, to have been either first or second, and the Alicante third. So much for the assertion that the majority of cultivators approve of this haphazard style of judging. Local societies are in the habit of engaging too many judges, little or no regard being paid to their qualifications. At least one good man of acknowledged reputation should assist to judge in each section at local shows.—W. IGGULDEN.

THERE is a paragraph in "Thinker's" paper this week which I think should not be allowed to pass without a protest. He states that in the "awarding of prizes for Grapes at exhibitions the whole question turns on the purpose for which the objects are staged," and that "in most cases this purpose is to make an imposing display that will attract the public and bring gate money," adding, "this being so, as I think it is, late varieties of Grapes cannot be excluded from summer shows." I think that, perhaps, the purposes and objects of horticultural societies and exhibitions were never before put on such a low ground as this. "Gate money" is the object. What does it matter, therefore, whether the fruits and flowers are in season or not, or whether the real object of cultivating them is served or not? In plain English this is "Thinker's" creed on the subject of shows. It has been often said that the original objects of horticultural exhibitions were becoming obscured by such motives and "purposes" as he describes, but no one has dared openly to avow as much before, and I do not know but that after all we are indebted to "Thinker" for his frankness. I read in the history of horticultural societies, as originally promoted by Mr. Knight, Mr. Wedgewood, Sir Joseph Banks, and others, that their purpose was to "encourage horticulture as a useful and humanising industry, and to promote a taste for flowers and habits of neatness and order among the humbler classes, &c.," and now we have the exponents of the subject putting such good purposes as these quite out of sight.

With regard to exhibiting late Grapes at summer shows, I have always thought that the practice was indefensible. Late Grapes are avowedly grown for winter and spring use, and for no other purpose, and the proof of the excellence and usefulness of such varieties consists in producing them in perfection at the season they are required. That being so, inducements to produce them months before they are wanted or fit to use only defeat their purpose. Take the Lady Downe's Grape for example. Its one good quality is that it keeps well, and but for that quality no one would prefer it to better Grapes like the Black Hamburg. What good is there, then, in offering prizes for such a Grape in summer and early autumn? In other words, if the object of encouraging the culture of the Lady Downe's Grape is its excellent keeping qualities, why not offer the prize for it at a season when these qualities can be proved? always assuming, be it remembered, that the "purpose" is the culture of a good late Grape, and not mere "gate money."—NON-BELIEVER.

MR. WARDEN seems to have entirely misunderstood what I wrote, and I thank the Editor for his footnote. I may say I have no desire to "encourage the growth of late Grapes for summer and autumn shows" solely for the purpose of having them displayed then. What I want is, that seeing late Grapes are shown at these shows in response to the invitations of prize schedules, justice should be done them, and other things being superior, they should not be debarred from obtaining the award simply because they are not shown at times when best for eating. I think this has been made plain enough all through this discussion. "Thinker" seems to have turned the question pretty well over in his mind before putting his "thoughts" to paper. I am glad to see him out once more, as, though he does not always agree with other able writers and experienced cultivators who are entitled to the greatest consideration, still there is very much that is interesting and instructive in his "thoughts," and they have the great recommendation of being written in a pleasant manner entirely free from mere carping criticism.

The meaning of my remarks on the disposal of Grapes after flower shows appears to me quite plain. No doubt Mr. Warden will admit this after again reading them, and also noting what the Editor has appended to his remarks. I hope that an agreement will be come to by all which will prove satisfactory, and that any cause for discontent may be removed. Our flower shows, as "Thinker" remarks, cannot be carried on without due regard being given to the gate money. To banish all late Grapes from our early autumn shows would take away a very attractive feature, and no doubt the consequences would be that financially shows would suffer. The public like appearances, and they must be considered when societies have to depend in a great measure on what is drawn for admission for their maintenance.—S.

MUCH has lately been written in your pages about judging Grapes

The clashing of early and summer season sorts with late or winter season varieties at September shows will always be unsatisfactory with both judges and exhibitors till some alteration is made in the arrangement of prize lists. Those who would limit the prizes to those in season I think make a great mistake, as it of necessity restricts the exhibitor to two or three of the leading sorts, and thereby limits the usefulness and interest of the show. It is disappointing for visitors, especially gardeners, when they seek in vain, amongst scores of bunches, for any other than white Muscat and Black Hamburgh. The general public may be pleased to look at and admire such a display, as they would with longing eyes gaze through the window of a first-class fruiterer's shop; but to the fruit-grower it has but a passing interest compared with that evinced at the late show at South Kensington. It was a very interesting show of Grapes, and I should say was satisfactory to judges, exhibitors, and visitors. Now would it not be possible for those engaged in promoting shows to try some means of having as many sorts represented as possible? Why must we always go on in the same old groove, "Two bunches so-and-so," or "Three bunches," as the case may be? Why have two or three bunches of one sort any more than having the same number of Dahlia blooms, one variety, in a stand of twelve (an idea that would be laughed at by our friends the florists)?

I see no reason why prizes should not be offered for eight, six, four, or two bunches, distinct. This, I feel sure, would, without any additional classes or larger prizes, bring to the local exhibition tables many excellent sorts of Grapes seldom or ever seen there, and by their presence lend a fresh interest to the show. "And what about the judging?" some will be ready to ask. I think their task would not be more difficult than it is at present, and I think their awards would, on the whole, be more satisfactory than they seem to be under the present system. As "Thinker" says, Give us good men who know what they are doing, and let them exercise their own discretion.—A WORKING GARDENER.

AUTUMN SHOWS.

EXHIBITORS of Chrysanthemums will soon be actively engaged in preparing for the numerous shows announced for the present season, and the following list of fixtures may be useful as a reminder. Secretaries of Societies not mentioned will oblige by forwarding their schedules.

October 21st to November 4th.—Chiswick (Pear Congress).
 October 27th and 28th.—South Kensington (Chrysanthemums and Vegetables).
 November 3rd and 4th.—Ealing, Southampton, and Lambeth.
 " 4th and 5th.—Brixton.
 " 5th and 6th.—Richmond.
 " 10th.—Southend and Putney.
 " 10th and 11th.—Brighton and Kingston.
 " 11th.—Basingstoke.
 " 11th and 12th.—National Chrysanthemum Society (Westminster Aquarium) and Croydon.
 " 12th and 13th.—Lindfield and Portsmouth.
 " 13th and 14th.—Sheffield and Huddersfield.
 " 14th.—Ramsbottom.
 " 17th.—East Grinstead and Devizes.
 " 17th and 18th.—Lincoln and Winchester.
 " 18th and 19th.—Northampton, Bristol, and Birmingham.
 " 19th.—Taunton, Hammersmith, and Aylesbury.
 " 19th and 20th.—Hull.

GARDEN NOTES.

WORKSOP MANOR.

THE garden at Worksop Manor, Notts, is at all times of the year well worth a visit by members of the craft; but perhaps at no time will they be better repaid for the time so spent than during the months of August and September, the weather being propitious, for then the fine terrace is ablaze with colour. There is abundance in the kitchen garden both of fruit and vegetables, and the numerous glass structures contain fine crops of Grapes, Melons, Pines, late Peaches, Nectarines, and Figs, as well as choice collections of decorative flowering and foliage plants.

A by no means uncommon failing amongst gardeners is that of thinking we possess something better or larger than other people have, and such thoughts are apt to give rise to conceit. Now, there is nothing takes the conceit out of a man (if he is conceited) so much as that of comparing the best of his products with that of his neighbours', when he often find that his Grapes, his Pines, his flower garden, his horses, or his pictures are not so uncommonly good as he thought. In the case of gardens, of course, we cannot convey them from place to place, nor is it desirable, but most gardeners can spare an occasional day or half day to visit some garden of repute in his vicinity, and if he is a man with his wits about him he will not fail to learn something, either what to do or what not to do, for the latter is not less important than the former.

Worksop Manor Gardens have this year well sustained their reputation for beauty and productiveness. Fruit has been plentiful on the wall trees; Peas, Potatoes, Beet, Onions, and Cauliflowers could scarcely be surpassed in quantity and quality. In the Melon house was a fine crop of beautiful Melons, a seedling of Mr. Sutton's, and in the next division was a fine batch of Calanthes. The Grapes in the second vinery were very fine in berry, well coloured, and useful bunches. The early vinery was cleared of fruit. The late vinery and Muscat house contained good crops of Muscat of Alexandria, Black Hamburgh, Gros Colman, White Tokay, Lady Downe's, Alicante, &c. Peaches and Nectarines were plentiful in the orchard house, and in the Fig house a heavy second crop of Figs (Brown Turkey) was ripening. All fruit was cleared out of the early Peach house, and the wood gave evidence of being well ripened. In an adjoining division was a splendid crop of Tomatoes, the plants being on a shelf and trained close to the glass. At the back of this range of houses is a house devoted to plants, and on the roof are trained three Lapagerias,

which are limited to a space of about 36 feet by 6, and in this space the flowers are produced by thousands, the very smallest shoots such as some growers have advocated being cut out, having developed three, four, and five flowers at a joint. One of these plants is growing in a stone trough which holds about 2 cubic feet of soil. These Lapagerias are worth travelling fifty miles to see.

The terrace was never more beautiful than it has been this season, and great credit is due to Mr. Sutton for its artistic arrangement. Not the slightest incongruity was observable, and the whole presented a charming picture, masses of brilliant colour being balanced by judicious grouping of foliage plants and carpet beds of greens and greys. Amongst plants used for edging and carpet beds were *Pyrethrum selaginelloides*, *Achillea umbellata*, *Antennaria tomentosa*, *Iresine brilliantissima*, *Alternanthera amabilis*, *Tradescantia zebrina*, *Centaurea ragusina*, *Herniaria glabra*, and *Mesembryanthemum cordifolium variegatum*. The brighter colours were given by *Pelargoniums Vesuvius* (scarlet), *Corsair* (scarlet), *Bayard* (crimson), *Waltham Seedling* (crimson), *Christine* (pink), *Master Christine* (pink), *Lady Middleton* (rose), *Emile Licau* (salmon), and *Lobelia Brighton*.

BLITHEFIELD.

On the 22nd of September I had the pleasure of visiting the gardens of Lord Bagot, Blithfield Hall, Rugeley. These have been for many years under the superintendence of Mr. Bannerman, and a better gardener Lord Bagot need not wish to have. Mr. Bannerman has made himself a name as a first-class Grape grower during the past twenty years, and has proved himself a formidable opponent at most of the principal horticultural exhibitions in the United Kingdom, and he is likely to do so in the future, judging by what is to be seen at Blithfield. That he is an enthusiast in Vine culture is readily detected as soon as one enters the vineries, and a question asked or a remark made concerning their principal occupants, and the fine crops of superbly grown and "finished" fruit hanging overhead demonstrate that he is a master of the art. Like other competent men, he can afford to impart to others some of the valuable information he has acquired through close observation and long experience, and that he does ungrudgingly, thus making an inspection of the vineries unusually instructive. One of the most striking features in this range was a Gros Guillaume carrying nearly 60 lbs. of well-finished Grapes. There were about twenty bunches in all, several weighing 5 to 6 lbs., and several others 4 to 5 lbs. So highly were they cultivated that only one berry in the total crop showed any appearance of not "finishing." Gros Colman was also worthy of special notice for their large and compact bunches, immense berries (above the average), and superb finish. A walk along the front of the vineries outside and an inspection of the borders gave evidence of the fact that Mr. Bannerman, like other first-class Grape-growers, believes in keeping the Vine roots as near to the surface as possible and consistent with safety. In several low houses Cucumbers and Tomatoes are grown in large quantities, whilst in others clean and healthy stock of Poinsettias, Calanthes, Gardenias, and Eucharises are being grown in quantity for decorative purposes. The Peach trees in the houses were in the best of health, foliage dark green and free from red spider, those in the early Peach house being so well ripened and clean that a shake of the trellis would cause the leaves to fall in showers, and as green as though the trees were in full growth.

The kitchen garden, about four acres in extent, is well cultivated, there being vegetables in quantity of high quality, and fruit in great abundance. In a large conservatory near the mansion are some large Camellias in robust health and well set with buds. The pleasure grounds and flower gardens, extending over fourteen acres, are picturesque and kept in admirable order. In close proximity to, and, as it were, forming a portion of the pleasure grounds next the mansion, is a small orchard, the only dividing line between it and the "dressed" grounds being a broad gravel path flanked with pillars and festoons of Roses trained over iron framework. To me, this orchard in such close quarters with the mansion and the prim flower garden, was an agreeable surprise, for I have never yet been able to understand why the masses of delicate white and lovely pink of our humble orchard trees in spring, and their wreaths of gold, crimson, and russet in autumn, should be relegated to some obscure corner of the garden or farm. I am quite sure that by such arrangements our pleasure grounds are deprived of some most lovely pictures.

INGESTRE HALL.

Returning to Ingestre, the first object that attracts attention is a new block of light, well constructed, span-roofed houses standing north and south, erected by Messrs. Halliday of Manchester. These houses are in four divisions, two of which are parallel to the others, and along the sides of each range, and forming a part of the whole, are useful frames or pits heated by hot water, and in these Mr. Gilman was having planted some thousands of Violets, principally Marie Louise and The Czar, with strong and promising crowns. The first division of the houses was devoted to greenhouse plants, of which there was a good collection; but the plants that attract the most attention were two magnificent specimens of *Dracaena latifolia*, these were about 10 feet high, and were clothed with their rich green and graceful foliage fully two-thirds down the stem, and not a withered leaf to be seen. It would be difficult to find another pair to match them in every respect. The next division is used as a stove and contains a miscellaneous collection of Palms and other foliage plants for house decoration. The first division of the other range is planted with French Beans to come into use from the middle of November, and very promising they looked. In the summer time this house can be used advantageously for the cultivation of either Melons, Cucumbers, or Tomatoes. The next division is filled with a fine healthy stock of

Calanthes, Euphorbias, and Poinsettias. It would be difficult to find a place where Poinsettias are better grown than they are at Ingestre. The low houses devoted to Gardenias are filled with the customary clean and healthy stock, and Ficus repens growing from the rafters of the fernery gives a charm to what would otherwise be an ordinary lean-to house, but which contains fine specimens and half-specimens of the usual cultivated Ferns. The Melon house was filled with beautifully netted and tempting fruit, the principal varieties being Bellmore Hybrid, Hero of Lockinge, and Eastnor Castle. An adjoining house was filled with Tomatoes bearing a heavy crop. The late varieties were filled with finely grown and finished fruit, Muscats, Alicantes, White Tokay, Hamburgs, and Gros Guillaume in particular. The Peach houses were nearly cleared of their fruit—and such fruit!—Salwey alone remaining. The trees promise to do as well in the future as in the past, and that is not saying a little as to their condition.

In the large conservatory the specimen Camellias are showing abundance of bloom, and the fine Dicksonias are in the rudest of health. There is a good specimen of *Grevillea robusta*, which reminds me that this elegant and easily grown plant is not so often seen as it deserves to be. Flower gardening, in the general interpretation of the phrase, is in abeyance at present owing to the building operations at the Hall, but the surrounding pleasure grounds are as orderly and well kept as though the family were in residence. In the frame ground were some grand Chrysanthemums for decorative purposes; they were sturdy husky plants, clean and well set with buds. By the side of the kitchen garden walks were several thousands of Strawberries in pots with thick, dark, and massive foliage and plump crowns, which promise to bring forth abundantly in due season. In one quarter of the garden was a splendid and regular crop of Brussels Sprouts. Mr. Gilman pins his faith to the old imported when it can be obtained true. Carrots were clean and abundant, as were all other vegetables. Hardy fruits of all kinds were plentiful. The walls of Mr. Gilman's cottage were covered by bright red clusters of *Crataegus pyracantha*, which are netted to preserve them from the birds, and are used in winter for decoration.—J. U. S.

FRUITS IN 1885.

THE season of 1885, speaking generally, is one of the best I ever remember, and, with but few exceptions, the majority of fruit trees have borne abundantly. Gooseberries were a good crop. There was a very heavy crop of Black, White, and Red Currants, and the fruit was of good quality, especially from young trees six and seven years old. Anyone having old stools of Black and Red Currants may mark a great difference in the quality of the bunches of fruit, as from a young plantation it is much superior, and, what is of equal importance, requires much less time to pick. The present is a good time to insert cuttings of Gooseberries or Currants or to buy young trees from the nurseries. A good dressing of decayed manure should be dug into the land previous to planting, and if possible choose a dry day. A good distance for the permanent rows is 6 feet apart, and the bushes 4 feet asunder.

Raspberries were plentiful, but Strawberries with me this year were a failure, particularly those on the south borders. The only crop I had worth speaking of was on the north border, where the soil was heavy and cool.

Plums have borne abundantly. Early Prolific, Victoria, Orleans, Mussel, Kirke's, Green Gage, Reine Claude Violette, Jefferson's, Coe's Golden Drop, Mitchelsou's, and the Red and Yellow Magnum Bonum have all had heavy crops. I never remember to have seen the Victoria so good as it has been this year. Of Damsons I have only a few trees, but the Prune Damson is particularly good. There is a Plum in this neighbourhood ripening about the first and second week in August that has done well this year. The cottagers know no other name for it than the "Wheaten" Plum; that is the name it has been known by within the memory of the oldest inhabitant, and is so called because it ripens about the same time as the Wheat. I have not seen its name in any trade catalogue, but it is an excellent Plum for preserves, resembling the Green Gage in flavour, and usually realises a good price in the market. It is quite green when ripe, of medium size, oval shape, and easily falls when ripe, so it should always be planted in an orchard with grass beneath to keep the fruit clean. All the trees I have seen have been so planted, as they find that much the easiest way to gather the fruit is to shake the trees and pick it up from the ground. It is propagated by suckers, and when about 6 feet high it bears fruit, never growing to a very great height. In some cases I have seen the suckers thinned out and left about 6 feet apart to form trees, cutting the old ones down when exhausted.

Old orchard trees of Apples in most cases have heavy crops of fruit. One of the very best for culinary purposes that rarely fails is Keswick Codlin. It has been in use from the end of July till the present time, October 1st. It is very prolific. One unpruned standard has had ten bushels of fruit picked from it. King of the Pippins also bears abundantly and seldom fails. Ribston Pippins are a good crop this year. Other varieties that are bearing well are Potts' Seedling, Striped Beeding, two very large varieties, as pruned bushes;

Nonesuch, Borovitzki, Hawthornden, Nonpareil, Adam's Pearmain, Minchall Crab, Dumelow's Seedling, Leydon Pippin, and Baldwin, the three latter being excellent keeping varieties. Some others have only partial crops, but those named are established and in full bearing.

Pears appear to be plentiful this year, and in most cases of good quality. More sunshine, however, is needed to finish off some of the late varieties. The first with me to ripen was Doyenné d'Été, a good early Pear for the end of July. Next came the Lammas, only second-rate, then Beurré Gifford and Jargonelle. Williams' Bon Chrétien followed next. This fine variety wants very little praise. Several trees of it should be planted in different positions in the garden to make its season last as long as possible. Orange Bergamot, a very old variety, is now in use and of good quality. It does well as an orchard standard. Louise Bonne of Jersey, Crasanne, Duchesse d'Angoulême, l'orelle, or Trout Pear, very handsome; Beurré Diel, Beurré Superfin, Beurré Rance, Chaumontel, St. Germain, Catillac, and a few others unknown by name to me are all bearing heavily.

Apricots were a good crop and required thinning; Moorpark was first-rate. Peaches and Nectarines bloomed well, but the east wind in the spring crippled the trees so much that there has been only a

Fig. 54.—*Miltonia cuneata*.

second-rate crop of fruit. Cherries, especially Morellos on a north aspect, were plentiful. Old orchard trees of Elton, Dukes, and Black Hearts in the neighbourhood had good crops of fruit.—A. HARDING, *Orton Hall Gardens, Hunts.*

MILTONIA CUNEATA.

THE *Miltonias* constitute a genus of handsome Orchids. The name was given in honour of Earl Fitzwilliam, who was an ardent admirer of plants of this nature. They are mostly natives of Brazil, and consequently require a warm stove temperature, especially during the season of growth. If given heat and a moist atmosphere few Orchids grow more freely or flower more profusely, and their richly coloured flowers are admirable for cutting and the furnishing of vases.

The plants will grow either in baskets or in pots; if in the latter it is necessary that they be potted very high—that is, the pots should be nearly filled with crocks; and the material, very fibrous peat, sphagnum, and charcoal, should be made to form a cone above the rim of the pot. The creeping stems from which the pseudo-bulbs grow should be pegged to the surface of the compost with small hooked pegs, and with good cultivation the plants will increase in size rapidly. If grown in baskets the plants require much the same treatment as *Stanhopeas* as to heat.

moisture, and rest. The species vary considerably in the size and colour of their flowers, but all are attractive and worthy of culture. *M. spectabilis* is white and violet, and is, as its name implies, very showy, as also are its darker varieties *atropurpurea* and *colorata*. *M. candida* has a white lip and yellow and brown sepals, while *M. cuneata*, the wedge-lipped *Miltonia*, is yellow and purple. The plants being epiphytal grow perhaps best in baskets, and will flourish in any plant stove where the summer temperature ranges from 60° to 90°, and the winter temperature 55° to 60°.

GROWING GRAPES ON THE STANDARD PRINCIPLE.

My attention has been accidentally called to an article on Grapes grown in a house 100 feet long, 30 feet wide, six Vines in a row, twenty-five rows, the Vines apparently drawn straight up to the roof, 15 feet high, by a wire. The variety grown was Black Alicante, and the results seemed very extraordinary. The houses belonged to a grower for market, a Mr. Church, near Norwich. I wish to know if others have experience in growing Vines on this plan and what they have to say.—T. RAFFLES BUTTRY.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 13TH AND 14TH.

APPLE AND PEAR SHOW.

THE remarkably successful exhibitions held at South Kensington this season are now drawing to a close, and it is very satisfactory to see that their interest is well maintained or even increased with the concluding shows. The Apple and Pear Show on Tuesday and Wednesday last presented an extraordinary gathering of those fruits, the Apples in particular being exceptionally good. There is also every reason to expect a similarly extensive display of Chrysanthemums and Vegetables at the final show of the series, which takes place on October 27th, when the Royal Horticultural Society and the Committee of the Inventions Exhibition will have every reason to be satisfied with the manner in which the programme has been carried into effect. That they have imparted additional features of great interest to the numerous attractions cannot be doubted for a moment by those who have seen that every day these shows have been held the conservatory has been the most crowded portion of the Exhibition, and on Tuesday last that building was thronged the whole of the afternoon.

APPLES.

The display of Apples was surprising, for many have complained that crops were short, yet it is evident that it is very far from being generally the case, as the competition was as keen in the majority of cases as could be wished under the most favourable circumstances. It is true the fruits were not quite so large, but for colour they were perfectly satisfactory in all the leading exhibits, and there were abundant fine fruits of the Warner's King and Peasgood's Nonesuch type. Worcester Pearmain and similarly highly coloured varieties imparted some beautiful tints, and the general effect was greatly heightened by the numerous dishes of these. The number of dishes in competition was about 1200, and with 500 contributed by nurserymen out of the classes, made a total of 1700, or over 10,000 Apples. The greatest number of exhibitors in one class was eighteen, that being the number of dishes of Blenheim Pippin staged in the class devoted to it, and it may be interesting to note that the five other Apples next to it in point of numbers in the single variety classes were Cox's Orange Pippin, 16; King of the Pippins, 15; Ribston Pippin, 14; Warner's King, 13; and Dumelow's Seedling, 11.

The principal class was that for a collection of Apples not exceeding 100 varieties, confined to nurserymen, in which there were five competitors. Messrs. G. Bunyard & Co., Maidstone, were deservedly awarded the premier prize for an excellent collection comprising some handsome examples of the best varieties, well coloured, and in the majority of cases of good size. They were also very tastefully set up on leaves, which added to the beauty of the exhibit. Amongst so many that were good it is impossible to name all that deserve note, but the following were some of the best represented:—Peasgood's Nonesuch, Lady Henniker, Mère de Ménage, Red Hawthornden, Dumelow's Seedling, Lord Derby, Early Julien, Lady Sudeley, Duchess of Oldenburg, Margil, Cellini, Winter Queening, Warner's King, The Queen, Cox's Pomona, Dutch Codlin, Cox's Orange Pippin, Grenadier, Yellow Ingestrie, Washington, Gascoigne's Scarlet, Melon Apple, Pott's Seedling, Lord Suffield, Dutch Mignonne, Scarlet Nonpareil, Emperor Alexander, Belle Dubois, Nanny Apple, Worcester Pearmain, Tower of Glamis, Winter Peach, Sykehouse Russet, Court Pendu Plat, and Sturmer Pippin. The second prize was gained by Messrs. J. & G. Lane, Great, St. Mary Cray, who had a pretty and varied collection, Messrs. Paul & Son, Cheshunt, taking the third place for even well-coloured fruits of the best varieties like those already named. In the amateurs' class for a collection not exceeding fifty varieties there was the same number of exhibitors, Mr. Sidney Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, leading with very handsome fruits, including a good proportion of brightly coloured varieties. The finest were King Apple, Mère de Ménage, Lady Henniker, Devonshire Queen, Hoary Morning, Warner's King, Golden Reinette, Emperor Alexander, Fat Ox, Thompson's, Poor Man's Profit, and Blenheim Pippin. Mr. D. C. Powell, Powderham Castle Gardens, Exeter, was second, and ran Mr. Ford very closely for the first position, as his collection was an extremely good one. There was a back of remarkably fine samples of Peasgood's Nonesuch, Bedfordshire Foundling, Mère de Ménage, Lord Derby, Annie Elizabeth, and Betty Geeson, the others being somewhat small but highly coloured. Mr. A. Waterman, gardener to H. A. Brassey, Esq., M.P., Preston Hall, Aylesford, was placed third, the coloured varieties, such as Worcester Pearmain and Ladies' Favourite, with Emperor Alexander, being very fine.

For a collection of a dozen varieties of kitchen Apples Mr. C. Ross, gardener to Charles Eyre, Esq., Welford Park, Newbury, was first amongst

the four competitors, showing handsome even fruits of Tower of Glamis, Mère de Ménage, Annie Elizabeth, Stirling Castle, Warner's King, Cox's Pomona, Peck's Pleasant, Lane's Prince Albert, Brabant Bellefleur, Hoary Morning, Earl of Derby, and Peasgood's Nonesuch. Mr. Powell and Mr. John Grey, Normanton, Stamford, were respectively second and third. There were twelve entries of six culinary varieties, Mr. F. Miller, gardener to J. T. Friend, Esq., Northdown, Margate, securing first honours with large fruits of Kentish Fillbasket, Emperor Alexander, Peasgood's Nonesuch, Annie Elizabeth, Blenheim Pippin, and Waltham Abbey Seedling. The second and third honours were accorded to Mr. Rutland, gardener to the Duke of Richmond and Gordon, Goodwood, and Mr. C. Ross, both of whom showed well in the class.

Of twelve dessert Apples there were six collections, Mr. Rutland there winning premier position with beautiful samples of Cackle's Pippin, Melon Apple, Nonpareil Russet, Cox's Orange Pippin, Brownless Russet, Nanny Apple, Kerry Pippin, Mannington Pearmain, King of the Pippins, Ribston Pippin, and Blenheim Pippin, the last-named being of particularly rich colour. Messrs. F. Miller and A. Waterman were the second and third prizetakers, the former showing Fearn's Pippin, Ribston Pippin, and Cellini well, while the latter had Duchess's Favourite, Worcester Pearmain, and Ribston Pippin equally good. Thirteen exhibitors staged in the class for six varieties of dessert Apples, Mr. Wm. Jacobs, Pound Street, Petworth, winning first honours with remarkably handsome fruits of Nanny Apple, Lady Sudeley, Incomparable, Ribston Pippin, King of the Pippins, and Cox's Orange Pippin. These were some of the richest-coloured fruits in the Show, and fully merited the position they were accorded by the Judges. Mr. Rutland followed closely, showing Nanny Apple, Cox's Orange Pippin, Melon Apple, Ribston Pippin, and King of the Pippins. Mr. C. Ross was third, his best fruits being Cornish Aromatic, Worcester Pearmain, Adams' Pearmain, Cox's Orange Pippin, and Margil.

The single variety classes were very interesting, and the competition in all of them was keen enough to render the judging difficult in several cases. Blenheim Pippin was shown by eighteen exhibitors, the generally good condition of the fruits and even size proving how useful a variety it is. The prizes were won by Mr. Rutland, Mr. Goldsmith, gardener to C. A. Hoare, Esq., Kelsey Manor, Beckenham, and Mr. Gilmour, gardener to the Right Hon. G. J. Goschen, M.P., Seacox Heath, Hawkhurst, in the order named. Cox's Orange Pippin was staged by sixteen exhibitors, Messrs. Bunyard & Co. leading with fine golden-coloured fruits, followed by Mr. J. Burnett, Deepdene Gardens, Dorking, and Mr. A. J. Thomas, Sittingbourne. Of Ribston Pippin there were fourteen dishes, all containing fruits of good size and colour. Mr. H. Folkes, gardener to F. F. Halsey, Esq., M.P., Gaddesden Place, Hemel Hempstead; Mr. A. Smith, gardener to W. H. Sewell, Esq., Warren Hill, Loughton; and Mr. C. A. Hoare, were the prizetakers in that order. King of the Pippins was finely represented by fifteen competitors, Messrs. G. Bunyard & Co. leading with extremely beautiful fruits; Mr. W. Bolton was second with examples but very few points behind, and Mr. Thompson was third.

Dumelow's Seedling was represented by eleven dishes, the winning samples from Mr. Richards, Somerley Gardens, Ringwood, Mr. Thompson, and Mr. W. Dance, gardener to Colonel Lowe, Gosfield House, Halstead, Essex, being large and even. Messrs. Ross, Richards, and Ford had the best of six dishes of Mère de Ménage, the first being the best coloured, and the second the largest. Messrs. Hudson, Bunyard, and Goldsmith were the winners with Golden Noble, the Gunnersbury Apples being of a very rich golden colour. With Cackle's Pippin, Messrs. Rutland, Ross, and Gilmour were the successful exhibitors amongst seven, but most of the samples were small and green. Court Pendu Plat was well shown by Mr. Rutland, Mr. Ford, and Mr. Sich, gardener to J. Abernethy, Esq., Margate, all being finely coloured, though like the six other exhibits in the class they were rather small. Messrs. Bunyard & Co. had the finest Warner's King of the thirteen dishes entered; Mr. J. Fincham, Nacton House, Ipswich, and Mr. Thompson following. Alfriston was shown by eight, but Gloria Mundi by only three competitors, the prizetakers being respectively Messrs. Neighbour, Powell, and Ford, Rutland Divers, and Bailey, of Shardeloes. Peasgood's Nonesuch was grandly shown by all the nine growers who entered. Mr. F. Miller was first with fruits fine in size, shape, and colour; W. Roupell, Esq., Roupell Park, was second, and Mr. Thomas third, with similar examples but few points behind. Lane's Prince Albert was capitally shown by Mr. C. Ross, Messrs. G. Bunyard & Co., and Messrs. E. & J. Lane, who were awarded the prizes in that order amongst seven competitors. A class was provided for Bramley's Seedling, but there were no entries.

PEARS.

The Pears were not quite so satisfactory as the Apples; there was a larger proportion of undersized fruits, and the majority were deficient in colour, the green ones predominating. The display was consequently less beautiful, and the entries were not so numerous, although there was good competition in many of the classes. There were 584 dishes in competition and about 260 not in the classes, the total of 844 being little more than half the total of Apples. The greatest number of entries in one class was twenty, in that for six dessert varieties, but, taking six of the leading single varieties, we find the following were the numbers shown:—Beurré Diel, eighteen; Louise Bonne of Jersey, seventeen; Marie Louise, thirteen; Beurré Superfin, twelve; Glou Morceau, twelve; and Beurré Rance, eleven.

In this section of the schedule, as for the Apples, there were two classes for large collections, one for nurserymen and the other for amateurs, but the number was confined to fifty varieties. Three entered in the trade class, Mr. A. J. Thomas, Orchard Lane Gardens, Sittingbourne, being adjudged the first prize for a meritorious collection, comprising beautiful examples of the following varieties:—Pitaston Duchess, Beurré Clairgeau Urbaniste, Louise Bonne of Jersey, Catillac, Fertility, Uvedale's St. Germain, King Edward, Duchess d'Angoulême, Beurré Diel, Napoleon, Doyenné Boussoch, Marie Louise d'Uccle, Maréchal de Cour, Beurré Hardy, and Vicar of Winkfield. Messrs. T. Rivers & Son, Sawbridgeworth, who followed, also had fine specimens of most of the varieties already named, together with Rivers' Princess, Rivers' Marguerite, Seedling Bergamot, Pitaston Duchess, and Zoe. Messrs. G. Bunyard & Co. were third, all their fruits being tastefully set upon variously coloured leaves in dishes.

In the amateurs' class Mr. J. Roberts, gardener to Messrs. Rothschild, Gunnersbury Park, was the most successful exhibitor, securing premier honours with handsome fruits of the best varieties set up in the same tasteful manner as the last mentioned. The most noteworthy amongst the varieties shown were Beurré Bosc, Fondante d'Automne, Napoleon, Gansel's Bergamot, Beurré Superfin, Pitmaston Duchess, Marie Louise d'Uccle, Doyenné Boussoch, British Queen, Catillac, Beurré Diel, White Doyenné, Van Mons Léon Leclerc, Grosse Calebasse, Easter Beurré, Louise Bonne of Jersey, and Winter Nelis. Mr. C. A. Houre was awarded the second prize for a collection of rather smaller fruits, but certainly good specimens of Williams. Bon Chrétien, Pitmaston Duchess, Beurré Superfin, Doyenné du Comice, Beurré Hardy, and Duchesse d'Angoulême. Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, was third with rather smaller examples of similar varieties.

A class was provided for twelve dessert varieties, in which there were seven entries, Mr. W. Allan, Gunton Park Gardens, Norwich, taking the lead with the following in praise-worthy condition: Beurré Clairgeau, Glou Morceau, Marie Louise, Beurré Diel, Doyenné du Comice, Marie Louise d'Uccle, Maréchal du Cour, Pitmaston Duchess, Winter Nelis, Louise Bonne of Jersey, Fondante d'Automne, and Beurré Hardy. The second place was accorded to Mr. Thomas, who had some especially fine samples of Pitmaston Duchess; and Mr. A. Waterman was third with well-ripened fruits of the leading varieties.

The class for six dessert Pears brought the largest number of competitors of any in the exhibition, twenty dishes being entered. Mr. Allan won the chief position with a beautiful half-dozen, the varieties being Doyenné du Comice, Pitmaston Duchess, Jersey Gratioli, Maréchal du Cour, Marie Louise d'Uccle, and Fondante d'Automne. Mr. A. Smith had King Edward, Brockworth Park, and Van Mons Léon Leclerc very fine in his second prize collection, Mr. Goldsmith being third. Of the ten entries with three dishes of stewing Pears, Mr. Rutland securing the first place with King Edward, Grosse Calebasse, and Uvedale's St. Germain. Mr. Johnston, Bayham Abbey Gardens, and Mr. M. F. Hatchett, Grove Park, Lee, were second and third respectively.

In the single variety classes the competition was generally good as in the corresponding Apple classes, but particular varieties were much better represented than others, as will be seen from the half-dozen previously named. Those specially provided for were as follows, the number of entries being given after each. Doyenné du Comice, six; Beurré Superfin, twelve; Maréchal du Cour, four; Marie Louise, thirteen; Glou Morceau, twelve; Beurré Rance, eleven; Beurré Diel, eighteen; Pitmaston Duchess, eight; Winter Nelis, 8; Beurré Bachelier, three; Passe Colmar, Urhaniste, and Beurré Benoist, one each; Fondante d'Automne, five; and Louise Bonne of Jersey, seventeen. The winners of the first prizes were Messrs. G. Bunyard & Co., Allan, R. Smith, C. Ross, A. J. Thomas, J. Rutland, Sich, and Johnston.

MISCELLANEOUS.

The non-competing collections both of Apples and Pears were very extensive, and comprised in each case representatives of all the principal varieties in cultivation, but differed slightly in size and appearance according to the district in which they had been grown. Messrs. J. Veitch & Sons, Chelsea, had a grand exhibit, for which a silver-gilt Banksian medal was awarded. There were 160 dishes of Apples and about the same number of Pears, all being remarkably fine, but especially the Apples. A silver Banksian medal was awarded to Messrs. W. Paul & Son, Waltham Cross, for 160 dishes of fine Apples and 100 dishes of Pears. Messrs. J. Cheal & Son, Crawley, were accorded a similar honour for 130 dishes of Apples and forty of Pears, the former being superbly coloured. Messrs. C. Lee & Son, Hammersmith, who had ninety dishes of Apples, all very fine fruits, were also awarded a medal of the same kind, a bronze medal being adjudged to Mr. S. Ford for fifty dishes of Apples and Pears. Mr. H. J. Thomas, gardener to J. Butler, Esq., Sittingbourne, showed handsome Pears, Louise Bonne of Jersey, Beurré Clairgeau, and Pitmaston Duchess being especially good. Mr. S. Jacobs, Covent Garden Market, was awarded a bronze Banksian medal for a huge Pumpkin weighing 213 lbs. W. Roupell, Esq., Roupell Park, also sent fifteen dishes of Apples and Pears, distinct varieties.

VEGETABLES.

Messrs. Sutton & Sons, Reading, offered five prizes for collections of vegetables, the varieties not stipulated, which brought an excellent display of well-grown kitchen garden produce, nine capital collections being staged, and so close in merit that it was not easy to select the winners. Mr. S. Haies, gardener to the Earl of Radnor, Coleshill House, Highworth, secured the leading honours for fresh, clean, handsome examples of Intermediate Carrots, Autumn Giant Cauliflowers, Canadian Wonder Beans, Schoolmaster Potatoes, Reading Perfection Tomatoes, Major Clarke's Celery, Rousham Park Hero Onions, and Sutton's Exhibition Brussels Sprouts. The second position was gained by Mr. W. Meads, gardener to the Right Hon. Viscount Barrington, Beckett Park, Shrivenham, for a collection very nearly equal to the first. Mr. W. Pope, Highclere Castle Gardens, Newbury, was third; Mr. W. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher, fourth; and Mr. G. H. Richards, Somerley Park Gardens, Ringwood, Hants, fifth.

COMMITTEES.

Both before the Fruit and Floral Committees there were sufficient exhibits to render the meeting interesting to add materially to the extent of the display, four rows of tables in the conservatory being fully occupied with Apples, Pears, miscellaneous fruits, vegetables, plants, and flowers.

FRUIT COMMITTEE.—Present Harry J. Veitch, Esq., in the chair, and Messrs. John Lee, J. Woodbridge, G. T. Miles, T. Francis Rivers, G. Bunyard, John E. Lane, J. Eilam, John Burnett, Charles Ross, Sidney Ford, F. Rutland, Wm. Paul, Arthur W. Sutton, T. B. Haywood, and G. Paul. Mr. C. Herrin, Chalfont Park Gardens, Gerrard's Cross, sent a bunch of his seedling Grape Chalfont Black, which was obtained from Madresfield Court crossed with Avercainy Seedling. It has a similar flavour to the fruit named, but is said to surpass it in its quick colouring and freedom from cracking. The berries were of medium size, and bearing a dense black bloom. Samples of Late Prolific Raspberries were also shown bearing a number of firm red fruits, and some large Cob Nuts, for which a letter and vote of thanks were accorded. Similar recognition was adjudged to Mr. G. Thompson, gardener to W. E. Wells, Isleworth, for large fruits of

Russian Transparent Apple and Souvenir du Congrès Pear. Mr. T. Laxton Bedford, sent dishes of the red Plum-like Dartmouth Crab (vote of thanks), the open air Tomato, which was referred to Chiswick for trial, and September Beauty, which was certificated. Mr. A. C. Roffey, St. Andrew's Villa, Church Road, Croydon, sent seed fruits of his Improved Telegraph Cucumber. Mr. W. Howe, The Gardens, Park Hill, Streatham, was awarded a cultural commendation for three bunches of Alicante Grape weighing 18½ lbs., and said to have been taken from a Vine bearing seventy bunches averaging 4 lbs. each. They were well coloured, the berries being of medium size. A cultural commendation was also awarded to Mr. A. Pettigrew, Cardiff Castle Gardens, for an exceedingly handsome fruit of Charlotte Rothschild Pine Apple, large, beautifully proportioned, and finely ripened. Messrs. J. Veitch & Sons, Chelsea, showed their Apple Bismarck, which was recently certificated at the Crystal Palace. The Committee thought highly of it, but require to see six fruits from a tree out of doors. Mr. R. Gilbert, Burghley Gardens, sent a green-flesh Melon of which the Committee think highly, but wish to see it again under more favourable circumstances; the flesh deep, and of a dark green colour. Burghley Champion Tomatoes were also shown very fine, the fruits large, even, and of a bright scarlet colour. Mr. W. Divers, Wierton Palace Gardens, showed several dishes of Apples and Pears. Mr. S. Ford, Leonardslee Gardens, showed Reine Claude de Bavay Plums in good condition; Messrs. T. Rivers and Son, Sawbridgeworth, had handsome fruits of Lady Palmerston, Salway, and Golden Eagle Peaches, and of Grand Duke Plums. First-class certificates were awarded to the following:—

Chou de Gilbert (Mr. Gilbert, Burghley Gardens).—This is described as a cross between Chou de Burghley and Brussels Sprouts, and has a large conical head like the former, with numerous large sprouts at the base, the stems shown being about 2 feet high. One member of the Committee speaks very highly of its flavour and good qualities as a vegetable.

Apple September Beauty (Laxton).—This was certificated at the recent Crystal Palace Show, and was described in that report.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., in the chair, and Messrs. J. Douglas, J. Laing, J. James, W. Beahy, W. Bennett, H. Herbst, W. Wilks, John Fraser, G. Duffield, H. Ballantine, J. Dominy, H. Williams, H. M. Pollett, James O'Brien, E. Hill, H. Turner, James Smith, J. Child, James Walker, W. B. Kellock, and Thos. Baines.

A grand group of Gladioli was staged by Mr. Alexander Campbell, Gonrock, N.B., comprising 170 spikes of the handsome varieties we have frequently commended. Very rarely are such fine examples of these flowers seen so late in the season, and the silver-gilt medal awarded was thoroughly deserved. Mr. T. S. Ware, Tottenham, had a varied and bright collection of hardy flowers, in which the early Chrysanthemums predominated, together with several pots of *Colchicum speciosum rubrum*, autumnale flore-pleno, and album flore-pleno, all beautiful bulbs for autumn flowering. A bronze medal was awarded. Mr. W. Bnll, Chelsea, showed several new and rare plants; *Alocasia reginae*, with heart-shaped metallic-like leaves, being notable, also *Lælia autumnalis atropurpurea*, with extremely rich crimson-coloured flowers. Mr. Cummins, gardener to A. H. Smee, Esq., Wallington, showed a plant of *Lycaste Smeana* with white sepals and petals and a small bright rosy lip; also *Cattleya speciosissima Ernesti*, which has blush sepals and petals, a white throat, and a crimson-tipped lip. Dr. Duke, The Glen, Lewisham, was awarded a cultural commendation for a well-grown plant of *Barkeria Lindleyana Centeræ*, which has been previously certificated. Mr. Stevens of Putney sent flowers of a neat Pompon Chrysanthemum named Early White Perfection.

Messrs. J. Veitch & Sons, Chelsea, contributed a group of greenhouse Rhododendrons, comprising a number of their superb hybrids, and some small plants about 8 inches high were bearing trusses of flowers. A cultural commendation was awarded for a magnificent plant of *Callicarpa purpurea* from the same firm, which was about 4 feet high, with long drooping branches, bearing large clusters of bright purple berries in the axils of the leaves. The peculiar but attractive *Amasonia punicea* was also shown in fine condition, its spikes of pale yellow flowers and bright red bracts being very effective. A cultural commendation was awarded to Mr. Hill, gardener to Lord Rothschild, Tring Park, for *Vanda Hookeriana*, with three strong growths and a spike of its lovely rich crimson-spotted flowers. A similar award was granted to F. A. Philbrick, Esq., Q.C., Bickley, for a plant of *Oncidium tigrinum*, with several large panicles of flowers. A vote of thanks was accorded to Mr. Maurice Young for plants of *Hedera Helix minima*, a variety with extremely small leaves produced closely on upright stems. Messrs. H. Cannell & Sons, Swanley, had a collection of fine Tuberous Begonia blooms, also Zonal Pelargoniums and the early yellow Chrysanthemum Fiberta, for which a vote of thanks was accorded. Mr. Forbes, Dover House Gardens, Roehampton, had a stand of new Japanese Chrysanthemums, one of which was certificated; and Mr. T. Sadler, gardener to C. Lambert, Esq., Oakhill Place, Leigham Court Road, Streatham, showed a stand of twelve magnificent blooms of *Elaine Chrysanthemum* with others. A silver Banksian medal was awarded to Mr. H. B. May, Edmonton, for handsome groups of Ferns and fine-foliage plants, most tastefully arranged.

First-class certificates were awarded for the following:—

Begonia John Heal (J. Veitch & Sons).—A graceful variety obtained by crossing *Begonia socotrana* with a seedling tuberous variety. It resembles the former in habit, producing light elegant flowers of a rich rose colour. It will probably form the commencement of a new race of winter-flowering Begonias.

Rhododendron Apollo (J. Veitch & Sons).—A grand variety with brilliant scarlet flowers in large trusses containing from ten to fourteen blooms.

Rhododendron Minerva (J. Veitch & Sons).—The best of the section, the colour a soft yellow with red stamens, fourteen or fifteen flowers being borne in a dense globular noble truss.

Eucharis Mastersi (W. Bull).—A beautiful addition to the genus, the flowers pure white, smaller than *E. grandiflora*, but without the cup or crown, which in that form is rather a disfigurement for bouquets or other floral decorations.

Pelargonium Alice Crouse (W. Beahy).—A double Ivy-leaf variety with large full rosy crimson flowers, a peculiarly soft yet rich tint.

Begonia Earl of Bessborough (H. Cannell & Sons).—A tuberous variety of dwarf compact habit, with large round bronze-yellow flowers, quite distinct in colour and free-flowering.

Chrysanthemum L'Isle des Plaisirs (Forbes).—A Japanese variety with flat or fluted florets, bright bronze red on the upper surface and golden on the lower. Of good substance and form.

NOTED TREES.

THE CHESTNUT.

THE Chestnut tree (*Castanea vesca*) is generally understood to be a native of Asia Minor, but it is abundant, at all events, as a naturalised tree in the mountainous parts of the south of Europe. The famous *Castagno di Cento Cavalli*, or Chestnut of the Hundred Horses, upon Mount Etna is probably the largest tree in Europe. It is so called, according to tradition, because Jeanne of Aragon and a hundred cavaliers of her suite took refuge under its branches during a heavy shower, and were completely sheltered from the rain. Brydone, who visited it in the year 1770, has given a particular description of it. He states it to have been 204 feet in circumference, but later observers reduce these dimensions to 190 or even 180 feet. It has the appearance of five distinct trees; but whether there were really as many trunks originally, or whether, as in the case of the Fortingall Yew, these trunks be merely portions of one great one, it is difficult to judge. Most travellers, however, who have examined it, incline to the opinion that the trunk is actually formed by the union of five stems all springing from the same root. A hut has been erected in the hollow space in its centre, with an oven, in which the inhabitants dry the Chestnuts and other fruits which they wish to preserve for winter, using at times for fuel pieces cut with a hatchet from the interior of the tree. The Chestnut throws up shoots very readily from the root, and Philippi says it is a general custom in Sicily to cut them down after they have attained a considerable size, when the new stems which are thrown out from the base shortly become trees again. This certainly furnishes a very weighty reason for supposing such to be the structure of the *Castagno di Cento Cavalli*; but there are other colossal Chestnuts also upon Mount Etna with undoubtedly single trunks. One of these, known by the name of the "Chestnut of St. Agatha," is 70 feet in circumference; another is the "Della Nave," which is 64 feet; and the third, called "Della Navella," is 57 feet. Some general idea of their age may perhaps be formed by a comparison with other individuals whose history is better known, such as that at Sancerre, described by Bosc, which, although only 33 feet in girth at 6 feet from the ground, has been called the "Great Chestnut of Sancerre" for 600 years. Though none of the English Chestnuts rival the Sicilian ones, yet there are some enormous ones in this country. That at Hitcham Priory, in Hertfordshire, had in 1789 a circumference of more than 14 yards, or 42 feet, at 5 feet from the ground; and though the internal part was decayed and hollowed by time, the external part and leaves were vigorous. Grose found four Chestnuts in the garden at Great Crawford Park, Dorset, 37 feet in circumference, and though shattered and decayed, it still bore good crops of fruit. The great Chestnut at Tortworth in Gloucestershire, and which is a signal boundary to the Manor of Tamworth, has, however, had dimensions as well as age assigned it belonging to few other English trees. In 1720 it measured 51 feet in diameter at 6 feet from the ground. Lysons, however, by later measurement, in 1791, made it out to be only 45 feet 3 inches. It bore fruit abundantly in 1788. In the reign of Stephen, who ascended the throne in 1135, it was already remarkable for its size. But even this tree, which has probably long since celebrated its thousandth anniversary, does not equal the smallest of the three Sicilian Chestnuts.

ORIENTAL PLANE.

The Oriental Plane (*Platanus orientalis*) is one of the largest trees of temperate climes. Pliny speaks of one in Lycia whose trunk, hollowed by age, presented a cavity 81 feet in circumference, in which the Consul Licinius Mutianus slept with eighteen persons of his suite; and Olivier, Dr. Walsh, and other modern travellers describe one in the valley of Bujukderé, three leagues from Constantinople, which is 90 feet high, and with a stem 150 feet in circumference. The trunk is hollow within to the level of the soil; the cavity is 80 feet in circumference, and occupies a space of 500 square feet. Vautier mentions one in Tiresia, near Pontus, which was 20 feet in diameter. There are no certain means of determining the age of these trees; but Hunter mentions, in Evelyn's "Sylva," that an Oriental Plane, planted in Norfolk in 1744, was at the age of thirty-one years 7 feet 9 inches in circumference at 1½ foot above the ground, which yields an average annual increase of 10 lines; and this calculation applied to the tree at Bujukderé would make it 150 years old, although if we consider that young trees increase much more rapidly than old ones, we might with safety assume it at between two and three times that age, or at least 400 years old. This is on the supposition that the trunk consists of a single stem, but the recent observations of Mr. Webb leave little doubt but this monster trunk is formed by the junction of several original trees planted in close proximity. Indeed, all along the shores of the Bosphorus, there are many groups of younger Planes, which for their shade have been designedly planted in a small circle, and their trunks will in time become similarly incorporated. Pliny's Lycian Plane may have also had such an origin.

THE ELM.

The Elm (*Ulmus campestris*) attains a large size, and lives to a great age. Mention is made of one planted by Henry IV. of France, which was standing at the Luxembourg at the commencement of the French Revolution. One at the upper end of Church Lane, Chelsea, said to have been

planted by Queen Elizabeth, was felled in 1745. It was 13 feet in circumference at the bottom, and 110 feet high. Supposing it were planted about 1570, its age would be 175 years, and its annual average increase in diameter about 3½ lines. Piffé's Elm, near the Biddington Oak, in the vale of Gloucester, was in 1783 about 80 feet high, and the smallest girth of the principal trunk was 16 feet. From the planting of Sir Francis Bacon's Elms in Gray's Inn Walks in 1600, and their decay about 1720, one would be disposed to assign the healthy period of the Elm in this country to be about 120 years. But De Candolle mentions one at Morges which fell down in 1827, probably undermined by the waters of the neighbouring Lake of Geneva. It was perfectly healthy, and had been growing in a favourable situation. A section of the trunk above the root showed it sage to be 335 years; at the same place the diameter was 16 feet 4½ inches English, and immediately below the branches, at 12 feet from the ground, it was 29½ in circumference; of five immense branches one was 15 feet 9 inches English in girth.

Of American Elms (a different species, however, from any of the European ones) the most noted is that upon Boston Common. Its girth at 5 feet from the ground (in 1844) was 16 feet 1 inch; at the height of 3 feet it measures 17 feet 11 inches, and near the earth 23 feet 6 inches. It is said to have been planted in 1670 by Capt. Daniel Hendman, then a schoolmaster in Boston, and who afterwards joined the artillery. It is therefore (1846) about 175 years old. In an old map of Boston, published in 1720, the Elm is delineated as a large tree. In 1800 there was a great hollow in it, large enough for a boy to hide himself in; but the cavity was then cleared of its rotten wood, and filled with a composition of lime, rubbish from old buildings, and clay. There is now no appearance of the hollow, and the tree is apparently as flourishing as ever. The Aspinwall Elm in Brooklyn is also of considerable size. It was planted in 1656; and in 1837, when 181 years old, measured 16 feet 8 inches at 5 feet from the ground, and 26 feet 5 inches close to the surface. These give the annual increase of growth of the American Elm very accurately at 4½ lines in diameter.—(*Forestry*.)

KITCHEN GARDEN.

TRENCHING.—We do not like to see an empty kitchen garden at any time of the year, but in late autumn and during the winter vacancies do occur, and from now onwards for the next four or five months ground requiring trenching must have attention. Our system is to trench a piece or two every winter, and we have never more to do than can be accomplished comfortably. Shallow soils are not the best, and for the majority of crops, and in most districts, the soil cannot be too deeply trenched. From 2 feet to 2½ feet at least is not too deep for the production of heavy high-class crops. Poor subsoils should never be turned on to the surface in any great quantities in one year. The first crop will not be very satisfactory, and when there is a great extent of bad surface supplies may be deficient. In dealing with bad subsoils we generally keep them in the bottom, and simply fork a quantity of rough rubbish and manure into the bottom of each trench to improve it there, and as this goes on it may be turned on to the surface in a few years afterwards. Three years ago we dealt with a stiff piece of clay land in this manner, and we are now trenching it again, with the result that the cold wet stiff bottom is found to be excellent soil for any vegetable crop. Where manure and refuse is scarce we have trenched ashes into wet soil with good results. We do not begin trenching a quarter to-day and finish it off to-morrow, but it is a "standing job" during the winter, depending upon what else there is for the men to do and the state of the weather.

DIGGING.—We dig every inch of our kitchen garden annually, and although trenching may not be necessary, digging must be done. Short spades are of no use for this work. They should not be put in at an angle, but straight down, and the soil should be turned clean over. At this time and on during the winter it cannot be left too rough, as the frost acts as a pulveriser.

ROOTS.—Carrots and Beetroots which have attained a good size will not become much larger, and they will now be safer under cover. The Carrots may be lifted with the aid of a fork if they cannot be drawn up freely, and the Beet may have to be lifted in this way too, but the utmost care is necessary that the skin should not be broken. The tops may be cut close in to the crowns in the case of the Carrots, but the leaf stems of the Beet should be left a few inches in length to prevent bleeding. When the roots are plentiful it may not be necessary to reserve the worst of them, and small and deformed ones can be used for the pigs, but where they are scarce it will be well to save all, as it is surprising what an obliging cook can do with inferior roots. As in the case of all other roots, these should only be lifted on dry days, and they may be stored as soon as they have become dry. A shed or cellar is a good place for them. Put them down in layers on the top of each other with a quantity of sand, ashes, sawdust, or ordinary garden soil between each. We prefer the latter, as it is always convenient and answers the purpose well. Do not lift autumn-sown Carrots; they will continue growing until Christmas or later and may be drawn up as required. Onions which were taken

under cover a little while ago should be cleaned and stored in their winter quarters. When being dried place them in a single layer, but when stored they may be put on each other until a large heap has been formed.

Salsafy and Parsnips may be left in the ground and lifted as required. White Turnips are the most tender, and those which are of a good size may be lifted and stored. They keep longer in this way than if left in the ground. Swedish Turnips and yellow varieties are much hardier, and need not be lifted until the weather becomes severe.

TOMATOES.—Gather all the green fruit of a naseable size before it is touched with frost, and hang it up in a dry glass house or room to ripen. Keep recently rooted cuttings in a cool house near the glass, and do not attempt to pot them this autumn. Dwarf compact plants are very desirable, and can only be grown in a cool house near the light.

CABBAGE.—Keep on all old plants which are producing a quantity of sprouts. These stand the winter well, and after they have had a little frost become as tender as the most delicate spring Cabbage. Plants which have been out in their bearing quarters for a few weeks may have a little soil drawn to their stems to keep them firm. Plant out more of the largest plants from the seed beds, and see that the slugs do not destroy them.

PARSLEY.—Provision should exist for a daily supply of this. Where it has grown very luxuriantly, and has now many large leaves which are beginning to wither, take these off and only allow the fresh green ones to remain. We never lift any Parsley to put in frames for winter, but when necessary we put hoops over the beds and throw mats over these. It is not very easily injured, and does better without any pampering. Kidney Bean and other seeds should be collected every other day at this season, as the damp soon injures the pods.

PLANT HOUSES.

Cyclamens.—If these are wanted in flower early, and the plants are now in a backward condition, the strongest and most forward should be selected and placed upon a shelf near to the glass. A close atmosphere must be avoided, or the flower stems as well as the foliage will draw up weakly. Arrange them in some light structure where the temperature at night can be kept from 55° to 60°, with a rise of from 5° to 10° from sun heat by day. Ventilate whenever the weather is favourable, and if very mild the ventilators may be open a little all night. If these conditions are carefully carried out the plants will soon commence throwing up their flower stems. If the plants are in small pots, which is generally the case when required for decoration, weak stimulants may be given every time water is required. Liquid made from cow manure and soot water is invaluable for these plants. All later batches may occupy cold frames for some time yet, or a light airy place in the greenhouse or any structure that can be freely ventilated and kept cool.

Double Primulas.—These must not remain in cold frames any longer, especially in low damp localities. They require a little more heat during the winter months than the single forms, and are best on a shelf close to the glass, where the atmosphere can be kept moderately dry and the night temperature 50° to 55°. With careful watering in such a position they will yield abundance of flowers. Weak stimulants are required after the plants have been flowering for some time, and we have found nothing better than clear soot water and an occasional application of artificial manure to the surface.

Single Primulas.—In placing these from the frames in which they have been grown to shelves in cool houses the plants should be sorted. This saves considerable trouble afterwards in the removal of the flowers from those that are not wanted for some time, and in drafting the strongest plants to the house in which they are brought into bloom. The earliest plants will soon push up their flowers in a light airy house, where a little heat is turned on at night and during dull damp days. The plants will be found invaluable for associating with Cyclamens, Roman Hyacinths, Zonal Pelargoniums, and other flowering plants next month. Plants in 3-inch pots are very serviceable, and some of the smallest are retained for flowering in that size. Plants for flowering after the middle of April should now be placed into 3 or 4-inch pots.

Calceolarias.—Frame room now being more abundant, these can be given a lighter and better position than they have been occupying up to the present time. The largest plants can be transferred at once into 5-inch pots, while the smaller ones can be potted if they need it. Those still growing in pans may be placed singly into small pots. At this season of the year small shifts only should be given, and the plants will be found to do much better than if large shifts are given to save the trouble of potting. These plants do well in a mixture of rich loam, one-third leaf soil, one-seventh of cow manure, and a liberal dash of coarse sand.

Cinerarias.—The earliest plants ought to be well advanced, and if placed from the frames into a light house they will come into flower early and prove most acceptable. They must be kept perfectly free from insects by slight fumigations with tobacco occasionally. Clear soot water should be given them every time they need water at their roots. Later plants that are in their largest pots can now be given more room in order that they can develop a good leaf growth without becoming crowded. The successional plants may be placed without delay into 5 and 6-inch pots, while those for late flowering that are still in pans should be placed at once into small pots. The smallest of these plants may be returned to the pans and potted singly in the space of a few weeks when they are ready. These will do very well for some time in frames.

THE FLOWER GARDEN AND PLEASURE GROUND.

Damage by Frosts.—The early and rather severe frosts experienced early in the week commencing September 27th was rather unexpected, and will have caused much damage to numerous plants that had not been protected. *Echeveria metallica*, *E. metallica glauca*, *Pachyphiton bracteosum*, *Sempervivum tabulaeforme*, and a few other tender plants are very badly damaged, and in all probability many will have lost their entire stock. In some cases, if they are potted at once, have all decaying leaves removed and be placed in a rather dry heat, the stems of the plants may push out a few shoots suitable for making into cuttings in the spring. Any other damaged plants, such as *Heliotropes*, *Iresines*, *Tropeolums*, *Ageratums*, and *Alternantheras* that it may be found necessary to take up, should have the frosted portions cut away, be given rather small pots, and placed in a rather dry heat, such as the shelves of a forcing house, and this may save a good many of them. If stood in a cold damp pit or frame the majority of them will rapidly damp off. In some gardens only a few of the beds are badly disfigured, and these, especially where the garden is in a prominent position, ought to have been cleared off and temporarily filled with either neat branches of variegated Hollies, Ivies, Box, and other hardy trees or hardy plants from the spare borders. For instance, quite a showy bed could be formed with Golden Pyrethrum next the edge, inside of this a band of dark Beetroot from the kitchen garden, and a centre of strong plants of *Cineraria maritima*, *Centaureas*, or pieces of variegated Holly. All Tuberous Begonias, where the position of the garden is low, and therefore liable to be more damaged by early frosts, are very badly cut up, and the sudden check may injuriously affect the bulbs' keeping properties. If lifted at once the soil should not be very closely cleared from the roots and as much of the uninjured tops be preserved as possible. They should be closely packed in shallow boxes and rather moist soil, and be stood in a frame or cool house and allowed to ripen gradually. Late Gladioli are also much injured, and these will not therefore perfect such good corms as usual. It is not advisable to disturb them yet, but those that are matured may be lifted, partially dried, and packed away in boxes of sand. Even the Chrysanthemums that were not yet showing colour are much injured, and in some cases ruined, but those that are yet in a promising state may well be lifted with a good ball of earth and roots, and be planted against a wall or in some other position where they may be protected with mats when necessary. The early-flowering Chrysanthemums are also much injured, and on the whole the beds and borders in many places are in a worse plight than they were last year at the end of October.

Roses from Cuttings.—During October and early in November is the best time for inserting Rose cuttings made from strong well-ripened growths. Those inserted last season struck remarkably well, owing principally to the well-ripened state of the wood and the immunity from severe frosts during the winter. It is the simplest method of increasing the stock of dwarf Roses on their own roots, and which succeed very frequently so much better than do those on the Manetti and Briar stocks. Those Roses with few or no thorns, such as John Hopper and Countess of Oxford, are the most certain to strike, but we have also been successful with nearly every sort we have tried. The long firm growths should be selected, rejecting the unripe portion of these, and cutting the remainder into lengths of from 10 to 12 inches. Each should be cleanly cut to a joint and have the lower half of the buds trimmed off. They should not be allowed to lay about several hours, this resulting in the loss of much of the moisture they contain and ending fatally, but they should be inserted in the ground as fast as they are made. An open spot should be selected for them, the soil being well worked, and will be all the better for an addition of horse droppings or old Mushroom beds and road grit, this being well forked into the surface, the cuttings to be dibbled in firmly to about half their length, taking care that each touches the bottom of the hole formed for it and is properly fixed with the point of the dibble. As they will form good flowering plants during the following summer it is advisable to give them plenty of room, or say not less than 12 inches each way. As a few of the cuttings usually fail, we prefer to place the roots 18 inches apart and the cuttings 9 inches apart in the rows, and in this manner the blanks are not so conspicuous. The strongest of those struck last winter may be transplanted in November or next spring, and in all probability will soon become strong free-blooming bushes, and which will remain vigorous much longer than those on stocks of any kind.

Planting Anemones.—Now is a good time to plant the fleshy roots of such kinds as *A. apennina*, *A. nemorosa*, *A. coronaria*, and *A. vernalis*, this supposing they are in a plump condition. When, however, they are newly bought in, and have been kept for some time in paper bags, they are almost certain to be somewhat shrivelled, and if committed to the ground in that state many very probably will decay. It will be found a safer plan to start them in boxes of moist sand, planting them out directly they appear to be commencing growth. They are most effective when planted either in patches of about six roots or in beds. The latter should be raised above the surrounding level, as badly drained positions or too much moisture is apt to prove fatal to the most delicate of them. If it can be afforded it is advisable to mix a good quantity of sandy loam with the ordinary garden soil. The drills may be drawn about 6 inches apart and 2 inches deep, and after a little sand has been added the roots may be planted 6 inches apart, and the bed levelled over. If no fresh soil is added to the bed the roots ought to be surrounded with a good sandy compost, and this will encourage a healthy start. Ranunculuses ought not to be planted till February, while the first week in November is usually found quite early enough for planting Hyacinths, Tulips, and various other bulbs.

THE BEE-KEEPER.

MARKETING HONEY.

THE honey harvest being now over, and the season on the whole having been a good one, many bee-keepers have a large stock of honey on their hands, and the question naturally arises, How they are to sell it?

If they wish to realise at once the only plan is to sell to any of the wholesale dealers, taking care, however, to get their money, as if we were eager to appear in a court of law as a defendant in a libel suit we could refer to cases within our own experience where honey has been sold, but the unimportant (!) part of paying has not followed. By all means let sellers beware to whom they sell their honey. Long prices look very well on paper, but for our part we prefer shorter prices—and cash.

Those bee-keepers, however, who wish the larger profits of selling without the middleman must take care to see that their honey is put up in an attractive form to tempt the public to buy. Honey may be divided for commercial purposes into two classes—honey in the comb, and honey out of the comb; that is to say, run or extracted honey. Of late years section honey has taken the place of the supers of glass, wood, or straw which were formerly so common, and the reason is not far to seek.

The sections, holding nearly one or two pounds, which are generally used, are neat and portable, and if packed in the glass card-cases are very attractive, and will save the bee-keeper the trouble of glazing each section, as unless the honey is protected in some way it will be spoiled by flies, wasps, &c. These cases for 1 lb. sections can be purchased from the hive-dealers for about 15s. the gross.

They consist of really two boxes without covers, the unglazed one being slightly smaller than the other. The section is put into the glazed box, and the other box fits over this, and is made all secure by the little projecting flaps of gummed paper. This doubtless is a considerable addition to the cost of a section, but as they can be used over and over again, any cases returned in good condition could be allowed for. We have frequently seen exhibits disqualified because they were not properly protected from robbing bees, and when judging at a show a short time ago we had to order the removal of a very meritorious exhibit of section honey, and which would have won the second if not the first prize.

The best way of cleaning sections from propolis, &c., is to use a sharp knife and scrape the section, as, if we use spirits of wine, ether, &c., there is generally a stain left on the wood. Run or extracted honey is best put up in glass jars or bottles, and must be carefully corked to prevent the honey leaking. Here again, the cost of the bottle bears rather too large a proportion to the value of the honey. What is wanted is an article which could be retailed for about 6d., very much in the same way as we see jam and marmalade sold in tumblers, &c., which, when empty, can be used for other purposes; but at present we have seen no such inexpensive method with regard to honey.

As regards the price of honey, it is difficult to determine. We have seen run honey (not extracted) sold for 2s. per lb., and we have heard of 1 lb. sections being sold for 6d. each, and in the last number of the *Bee Journal* extracted honey of good colour is offered for 6½d. per lb.

Whether the price of honey will rise during the winter will depend on the demand, and bee-keepers must judge for themselves whether they will hold back or sell at these low prices. If they decide to keep their honey on the chance of getting more later on, they must be careful to keep the honey in a warm dry room, and never covered over until it is fully ripened. A good way to prevent fermentation is to cover the vessels containing honey with unsized paper, which has been dipped in a solution containing one part of salicylic acid to ten parts of spirits of wine. If, however, any fermentation

takes place, the honey must be heated and then carefully skimmed; but this is only of use when fermentation has only just begun, as, after a short time, fermented honey is of no use except for making vinegar.—THE SURREYSHIRE BEE-KEEPER.

THE LAST CHANCE.

SEPTEMBER has passed away, and has not failed to give warning that frost of some severity may shortly be experienced. Unless to repair the neglect of the earlier part of last month no manipulation should now be undertaken, but the bees should by perfect quietness and freedom from interference be allowed to settle comfortably down ready to meet the unkind weather they are likely, at no very distant date, to experience. All unions should now be effected, but most thoughtful bee-masters will already have performed this most salutary operation. Unity is strength: a strong hive now will be strong in spring, and will amply repay any extra expense incurred in the purchase of some pounds of bees if there are no honey stocks to afford the necessary contingent. The stronger a stock is in autumn the greater the yield in spring; the better the foundation the firmer the structure. The seed bed must be in good condition to insure a healthy growth. So must the stock from which the swarms of a future year are expected; or, if the swarms are prevented increasing, must be full of bees with a plenteous store, in a warm hive sheltered from the cold north wind, protected from the rain and damp, freed from vermin, and tended at times, when care is required, by the owner, who is acquainted with the different wants and requirements of his busy insect labourers.

There is, it must be admitted, one fear in connection with buying bees, and that is the importation of foul brood. But with discrimination and due care to buy only from men whose honest dealing and acquaintance with the appearance of a foul broody stock is assured, this danger may be reduced to a minimum. Food, too, must be administered if a full supply has not already been given, and it is here that the greatest care is requisite to prevent "robbing." A little syrup spilt will cause a great disturbance, and if measures be not taken at once to stop the thieves, much mischief may be done, although here again by keeping all stocks strong in numbers, an excellent preventive will be afforded and less loss entailed.

This reminds me that early in August I had a bad case of robbing, but taking stringent measures, and losing no time in their application, peace was soon restored, and no further outbreak has occurred. I was feeding a driven stock of great strength with the ordinary round tin feeder, and although covering the feeder well up, the bees, while not venturing inside the hive, managed, as I afterwards discovered, to get a little syrup from the feeder direct, owing to a flaw so small as scarcely to be perceivable. It was on Sunday morning the "row" was at its height, and on the next morning peace was almost wholly restored. The measure I took was harsh. On the top of the hive, enveloping both it and the feeder, I laid a carbolic sheet. This I should hardly have dared to do had I not been at home to see the result, as driven bees not having any particular attachment to a hive containing no brood, and strongly scented with crude carbolic, might possibly I thought leave the hive. They were, in fact, driven from the feeder; but the robbers, they hovered round and round, and endeavoured to resume their work, but in vain, and gradually their efforts became more feeble. At night the sheet was taken away, a filled feeder placed in the stead of the one the cause of the disturbance; the bees taking possession at once, went peacefully on with the work from which they were compelled to desist by the strongly scented carbolic. So far as I am aware, no robbers have since attempted to assail the stock, which, to their great disgust, they found, when expecting a stolen feast, possessed of a vigilant, if inanimate, assailant of incalculable value to the bee-master. My bar-frame hives are packed for winter in a manner advocated by many as an effectual means of preventing dampness, and to my mind rightly so. Ticking, quilts, and then a section crate filled with cork dust on the top, as warm as possible, clean, admitting of easy ventilation, carrying away the damp, there seems to be no more admirable winter covering.

To a careful apiarian the winter season brings no fear, because he knows his bees are well provided with all the necessities they require to withstand the season. But how different is the case; and I once, and only once, experienced it, of the man who has stocks not strong in numbers nor well supplied with food, and if to this be added an insufficient covering, a very climax of misery must be reached. Each day he fears to find his stock dead; and when, in the latter end of January, mild weather enables him to partly repair his previous neglect by

giving a supply of syrup, his troubles are by no means at an end. Insufficient food in winter, coupled with paucity of bees, generally cripple a stock to such an extent that the honey harvest is, if not over, at any rate far advanced before there is the slightest chance of obtaining surplus honey. Such a stock, indeed, drags on its weary way, yielding no profit, affording no pleasure, but it is a perpetual eyesore, reminding the neglectful owner of what "is might have been."—FELIX.

QUEENLESS HIVE—BEE SLAUGHTER.

I HAVE had some little doubt as to the state of one of my bee hives lately. The one I speak of is a frame hive. It swarmed three or four times; the bees, however, always returned, and it was apparently very strong both in bees and honey. It made a sort of attempt at the usual time to kill its drones, but in a very mild way, and after a few days that ceased. I therefore examined it. I could not find a queen, there was no brood, not very many workers, a fair quantity of honey, and a large number of fine drones. I suspected there was no queen, but they were very irritable, and did their best to sting me and my assistant, but we were well protected.

On October 1st I procured a driven swarm, and joined them to my frame hive, taking the usual precautions as to feeding both sets of bees and giving a little smoke. The following morning I removed from the entrance a large quantity of dead bees, most of them appearing as if they had been dead for some days. No dead drones were brought out, but dead bees were dragged out all day.

On October 3rd, at 2 P.M., the drones and bees came out in large numbers suddenly, as if about to swarm; the bees ran about on the entrance board, fed one another, and flew out. After a time they gradually returned. On October 5th the weather was bad, but a few bees were still dragged out, though they were settling down. October 9th the bees are again dragging out the drones, both dead and alive, in a slow way, but evidently more seriously than they did three weeks ago, and more bee bread is coming in. Altogether, there is a more business look about the bees. The weather is still cold and stormy. Will your Lanarkshire correspondent kindly explain the cause of all these proceedings? Am I now to hope that I have a healthy queen? I do not like opening the hive if I can help it.—A BEE-KEEPER IN DUMFRIES-SHIRE.

[There is little doubt from the description given that the hive was queenless, but the driven swarm now added and carrying pollen indicates all is right again.]

The returning of swarms arises from various causes. A common one is where many queens are in the swarm; or it may be that the old queen, from some defect, does not leave the hive, but is ultimately killed by some of the young queens being hatched which were being brought forward to supersede the reigning one.

Bees in queenless hives are sometimes liable to sting on the slightest interference. A drop or two of the oil of peppermint is more effective in gaining swarms than smoke, which in large quantities injures both bees and honey.

The most successful way of joining two or more swarms together is by driving both into empty hives, then, after both are fed, knock them together. Where there are combs, one or both of the bees soon empty themselves, and, where no scent has been used, often result in one or part of both being killed, the conquering bees always managing to cause the rivals to disgorge their honey.

The reason no dead drones were dragged out at first was probably the onput bees being killed, and the great rushing out was perhaps because the queen was encased—a ruse by the bees, as if swarming, to induce those encasing the queen to liberate her, or it might be simply a rally after the battle to put all right, when the slaughtering of the drones and pollen-carrying took place. Sometimes most of the bees killed remain on the floor till carried out, which occupies the bees a day or two. Others are simply wounded, leave the hive of their own accord, and are never observed unless watched for.

A queenless hive does not always retain the drones, neither does one with a young and fertile queen kill them at the usual time. I have one of the latter at present, a young and very prolific queen, which is a perfect treat to see carrying pollen, as well as to hear the deep hum of the drones ringing in the air, reminding us of all the joys of summer weather while it is actually winter, snow and hail falling at intervals, with 9° and 10° of frost at night, but with some sunshine through the day.—A LANARKSHIRE BEE-KEEPER.]

DRIVEN AND FED BEES FOR STOCKS.

ON Sept. 19th I drove from three straw skeps 9½ lbs. of bees, and united them in a hive 17 by 12 inches. I divided half-pound foundation comb over the bars (eleven). The bees commenced on all the bars at once, and have built comb fully half way down. I have given them 30 lbs. of best crystallised sugar with nearly its own weight of water made into syrup, but for the last two days they are not taking the syrup as freely as they did at first. What can be the cause of this? I intend to give them another 5 lbs. of sugar. Would that be enough to keep them all right until spring? They are not building comb so fast as they did, but they are carrying in great quantities of pollen every dry day. Will bees treated in this way throw off swarms next year?—J. E.

[The bees referred to seem to have done fairly well considering the very cold and boisterous weather prevailing both in September and the present month. The quantity of syrup given is sufficient to tide the bees over till spring, but it would be better could the bees be induced to build down their combs now, as by that means an excess of drone comb would be avoided. The cause of the bees ceasing to feed arises from two causes—1, The extreme cold; 2, Sitting closely and nursing their brood, which the carrying of pollen indicates there is a good deal of it in the hive, and, what seems better, that it is a young queen they have at their head, which, if so, will do well next season in spite of all any old "fogey" may say to the contrary. As milder days are to be expected yet keep feeding them. The best of all feeders for the purpose is the frame-feeder as recently described. Bees both in autumn and spring when sitting closely upon brood do not feed rapidly, and will sometimes die before they will leave their charge to feed, particularly when the syrup is placed away from the cluster. The frame-feeder places the syrup close to the bees, and as it is wood well waxed they feed from it when all other feeders are deserted.]

THE HONEY MARKET.

I NOTED the above article on page 327, and although not a bee-keeper I should like to say that I have seen exposed for sale in the grocers' shop windows in Lynn sections of honey at 8d. each. It was very good, the cells being well filled and the colour grand. For my own consumption I pay 1s. per lb. for run honey.—STEPHEN CASTLE, West Lynn.

TRADE CATALOGUES RECEIVED.

Dammann & Co., Naples.—*Catalogue of Flower and Vegetable Seeds.*
Thomas Roberts, 112, Victoria Street, Westminster.—*List of Stoves (Illustrated).*
Bandriller, Angers.—*List of Fruit Trees, Ornamental Trees and Shrubs*
Richard Smith & Co., Worcester.—*Catalogue of Stove and Greenhouse Plants.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Seedling Primula (J. C.).—The variety is a pretty one, and worth preserving, but it would not possess any great trade value, as there are others of similar character.

Lord Palmerston Peach (F. B., Lankhills).—Although we have seen larger fruits, we have no hesitation in saying that yours "weighing 9 ozs. is a satisfactory size for an amateur," as it is above the average of amateurs' productions in Peach culture.

Large Tomatoes (E. S.).—Your Tomatoes, borne by plants raised from cuttings in October of last year, are larger than those sent by "J. W. L.," but not quite equal to them in shape, firmness, and colour, and had the two lots been in competition yours would have had the second place. Your fruit, weighing 1½ lb., is heavier than any we have received this year.

Fasciated Tropæolum (Miss H.).—The name of the plant No. 1 is Tropæolum tuberosum, which is quite distinct from T. speciosum. No. 2 is, we suspect, an abnormal form of the same, or a seedling variation from it. It is much fasciated and very curious. We know of no method of inducing it to flower other than growing plants in a very light greenhouse. Perhaps if you were to strike cuttings now and keep the young plants steadily growing on a shelf near the glass through the winter they would flower next year. If it is a form of T. tuberosum, as we suspect, the distinctive affix of fasciatum would be appropriate.

Camellias (W. Kruse).—There are so many superior varieties of Camellias that we suspect it to be quite impossible for anyone to name half a dozen varieties that would be universally admitted as the "best." Some are best for flowering in a comparatively small state in pots, others for attaining large dimensions planted out. The following are good free-flowering varieties:—Alba plena and Mathotiana alba, white; Marchioness of Exeter and Sarah Frost, rose; Madame Lebois and Bealii, crimson; Comtesse Lavinia Maggi, striped; and Giovanni Santorelli, marbled. You can exclude any two of these according to the colours you prefer.

Peaches on Shaded Wall (J. T. W.).—If you remove the Peaches it is very improbable that you will succeed in covering the space with fruitful growths of any other trees you may plant. Victoria Plums would be as likely to succeed as any, but there is no certainty about these. Cannot you lower the front trellis, bending it over in the form of an arch to the side of the walk, securing it there about 3½ feet from the ground, or so that the sun would shine over and reach the trees on the back wall? If you cannot do this you might cover the wall with Camellias which grow well in the shade.

and are hardy enough for unheated houses in the south of England; but you omit to state the district in which you reside.

Insect Cocoons (W. M., Hatfield).—The objects you enclosed are cocoons, produced by a species of sawfly which has no popular name, but is termed in science *Trichiosoma lucorum*. As the specific appellation implies, the insect occurs upon a variety of trees and shrubs, but the larvæ or grubs chiefly consume the leaves of the Whitethorn, Blackthorn, and Rose. Occasionally they occur upon fruit trees, but as the females scatter the eggs here and there it is seldom abundant enough in any locality to produce serious injury to any cultivated plants. After attaining maturity, the larvæ form these cocoons, from which the flies emerge during the spring. If opened now, they will be found to contain the larvæ closely rolled up and motionless; they eventually change to pupæ, in which state they pass the remainder of the winter.

Exhibiting Chrysanthemums (E. C.).—There is quite room in the box illustrated on page 301 for the blooms when cupped and placed in the stands. The exhibitor to whom you allude uses cups, as do all others who succeed in winning the best prizes. Some blooms are so perfect that nothing will improve them, but the majority appear to much better advantage in stands when cups are employed.

Water Lily not Thriving (G. G.).—We suspect you have not got the hardy pink Water Lily, some of the coloured species requiring heat. As you purchased the plant we presume it would be named, and if you will send the name your letter shall have further attention; also please state whether you want two other aquatics for the open air or the vinery, in either case stating the size of the tank.

Preserving Walnuts (H. J.).—If you have no cellars at your command we should place the nuts in large earthenware pipkins, or failing these in large flower pots, and bury them in a cool position in the garden. We have kept nuts successfully by this simple method. In some of the pots we have mixed sand with the nuts, others sawdust, and in other pots the nuts have been placed without either sand or sawdust, and there was little or no difference in the results. Walnuts may be kept for a considerable time in an ordinary shed if they are placed in pots with moderately moist sawdust, but not that from Fir trees, which contains turpentine.

Bone Dust for Vine Border (A. B.).—The quantity of bone dust that should be used depends on the condition of the Vines. If they are the reverse of luxuriant a quarter of a pound lightly pointed into each square yard of the border will not do any harm, neither, perhaps, will it do much good if there are not plenty of fibrous roots working not far from the surface of the border. A great deal of manure is wasted on Vine borders that contain little beyond straight fibreless roots a foot or two below the surface, and the chief feeding roots, as is often the case, far beyond the confines of the border.

Manure for Mushroom Beds (T. W. D.).—The manure collected from the London stables for Mushroom-growing is not weighed. It is true the size of carts vary, but, as stated in "Mushrooms for the Million," the manure is "stacked square 2½ feet above the top of a full-sized cart," and this you may take to mean the largest carts in regular use in your district. Manure that is sold by the ton about London is too much decayed for the purpose in question. One of Mr. Barter's loads would perhaps not weigh much, if any, more than three-quarters of a ton, and if he pays 3s. 6d. per load and sells the old beds for 2s. 6d., and you pay 8s. 6d. per ton and sell for 7s. 6d., you appear to be on a level with him as to profits; for if you buy at a higher rate than he does you would naturally sell at a higher rate too; and the value of the crops of Mushrooms grown in the meantime, assuming them to be equal in bulk and quality, would necessarily be the same in both instances.

Grapes (V. A. Brown).—Your questions were answered on page 261, No. 273, the issue of September 17th. Dr. Hogg Grape is not a Muscat of the type of Muscat of Alexandria, which has large oval berries, but is a Frontignan with much smaller and round berries, with a rich Muscat flavour. It will succeed in a house in which Black Hamburgs ripen in August, assigning it a warm position. The same remarks apply to Gros Maroc, but this is a very strong grower, and requires a width of 5 feet of roof space. Alnwick Seedling will ripen in a Hamburgh house in which the Vines are started in March, and a suitable temperature is maintained for their healthy growth. Foster's Seedling is the most reliable white Grape for growing with Black Hamburgs, and with good cultural attention the berries neither shank nor crack.

Potting Violets (X. X. X.).—You had better take up and pot your Violets at once, removing all decayed and discoloured leaves, also worms from the soil that adheres to the roots, yet as much of this should be retained as can be conveniently placed in the pots. Use fresh loam with a sixth part of manure so much decayed and dried that it can be rubbed through a sieve, adding also a little wood ashes and sand to render the mixture porous. Work this well amongst the roots, then press it down firmly, giving a good watering. The plants should be placed in a frame, which may be kept close, and even shaded for a few days, if that is necessary to prevent the leaves flagging, but the less of shade the better if the leaves can be kept fresh. When the plants have recovered from their removal they require much light, and all the air that can be afforded without checking the expansion of the flowers by sharp currents rushing through the sashes.

Clematises (T. T.).—You appear to require some of the free-growing or rambling varieties, on which a correspondent wrote as follows a short time ago:—"All the species and varieties of this genus are admirably adapted for covering walls or any blank spaces, or for covering a verandah, porch, trellis-work, or bower, or, what is more to our purpose here, for scrambling over old ruins, rookery, or rockwork. In such places even the common English species, *C. Vitalba*—Traveller's Joy, as it is frequently called, in some localities more frequently known as Old Man's Beard—is extremely ornamental. *C. Flammula* is a deliciously fragrant old species, of which there are several forms. All, however, are white and sweet-scented, differing only in size and robustness. The leaves are small, pinnate, and dark green, whilst the pure white fragrant flowers are borne on branching panicles in great profusion throughout the summer and autumn months; and *C. montana* is special valuable on account of its blooms appearing so early in the year. Th

flowers are large and pure white, with pale green stamens, appearing in April and May. The following are mostly hybrids, which have been raised in this country, and flower somewhat in the order named:—Albert Victor, large, deep lavender, barred with brown; Alexandra, petals broad, reddish violet; Azurea grandiflora, violet blue; Cœrulea odorata, small, dark purple, very fragrant; Fortunei, creamy white, double, fragrant, Japan; Gem, rich blue, continuing into late autumn; Lady Lovelace, double rich blue; Lord Londesborough, deep rich mauve, striped maroon; Lady Londesborough, silvery grey, with pink base; Lanuginosa, large azure blue, China; Lanuginosa candida, large, creamy white; Lanuginosa nivea, large, pure white; Lucy Lemoine, large, double, pure white; Magnifica, purplish crimson; Miss Bateman, large, pure white, striped with creamy white; Jackmani, large, rich violet-purple, a profuse bloomer; Prince of Wales, deep vinous red, shaded violet; Rubella, large, deep claret; Rubro-violacea, maroon, shaded violet; Standishi, violet-purple; Star of India, rich plum, red bars; Thomas Moore, large, rich purplish violet, white stamens; Tunbridgensis, fine shape, deep bluish mauve; Velutina purpurea, large, rich purplish black.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (A. M. Turner).—Cornish Giliflower. (H. Hewat Crawl).—American Mother. (X. Loughgale).—Loddington. (Alfred Brook).—1, Fearn's Pippin; 2, Brickley Seedling; 3, not known; 4, Ord's. (S. C. Clay).—Suffolk Thorn, gather it now and keep till it is ready. (J. L. H.).—1 and 4, Northern Greening; 2, White Nonpareil; 3, London Pippin. (James Woods).—Apple, Keswick Codlin. Pears, 2, Easter Beurré; 5, Beurre Sterckmans. (W. S.).—1, Calabasse; 2, Beurré Diel; 4, Hacon's Incomparable; 5, Gillogil; 6, Duchesse d'Angoulême. (W. G.).—A, Forelle; B, Beurré Diel. (A Constant Subscriber).—1, Gloria Mundi; 2, Reinette de Canada; 3, Gravenstein; 4, not known; 5, Hambledon Deux Ans. (C. J. Nicholson).—1, Hollandbury; 2, Stoup Leadington; 3, Greenup's Pippin. (South Essex).—1, Golden Reinette; 2, Bess Pool; 3, Braddick's Nonpareil. (R. E. Filkins).—2, Hollandbury; 5, Ribston Pippin; 6, Northern Greening.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (G. H.).—1, Hibiscus syriacus; 2, Mesembryanthemum echinatum; 3, Davallia canariensis; 4, Davallia bullata; 5, Selaginella Martensi.

COVENT GARDEN MARKET.—OCTOBER 14TH.

SUPPLIES and prices continue much the same as last week.

WHEAT SOWING.

Now that the time for sowing Wheat has come again, many a farmer has to consider if it is worth while making any reduction in the number of acres of land for the cultivation of a crop which in many, perhaps in the majority of farms, has proved to be so unprofitable again. Free trade has brought us into competition with the Wheat-growers of other countries; we have now to offer our samples for sale in the world's market. Are we to withdraw from the contest beaten? It is undoubtedly a wiser course to bow to the

inevitable than to struggle on hopelessly against it; but before doing so we ought certainly to see for ourselves if failure in this important matter is really inevitable. In doing this let us omit nothing, but weigh well the cost of foul land, inferior seed, long fallows, farmyard manure with the heavy expenditure involved in its manufacture and use, and then let us strive to master fully the advantages of clean land, no long fallows, the application of manure either in the form of pure artificial home-mixed manure, or of green crops ploughed into the soil, of good seed of the best sort, of a reduction both in horse and manual labour upon the farm. How seldom do we meet with a field of White Wheat, and yet there can be no good reason why it should not be grown extensively upon farms south of the Trent. We were recently asked by a tenant farmer for a reduction of rent upon the plea that his crops did not "pay," adding, by way of illustration, that he had only got a yield of 24 bushels an acre of Red Wheat this year, and he had just sold it for 3s. 9d. per bushel. Messrs. Webb, of Wordsley, Stourbridge, send us extracts from a letter published in a newspaper, and written by Mr. Evan Baillie of Filleigh, to the effect "That from a field which has been considered the poorest on Newhouse Farm, in Chudleigh parish, there has this year been grown, thrashed, and winnowed White Wheat at the rate of 47 bushels per acre. The straw was 6 feet high;" and after telling how the land had been drained, ploughed fairly deep, and cleaned from weeds, he adds: "The inferences to be drawn are, I think, these—first, that under certain favourable conditions, such as having the land in good order, the best seed, and a good season, Wheat may still be grown at a profit; and, secondly, that it is, at least, more advantageous to farm well than to farm badly. Whatever goodness there was in the soil the Wheat plants had the whole benefit of it, there being no weeds to rob them or to choke the good seed." Mark the contrast of results, and let us go a little further and see something of the returns per acre under what may fairly be considered ignorant and intelligent methods of culture. In recent quotations from Mark Lane we have the best Kent or Essex White Wheat at 38s. per quarter, or 4s. 9d. per bushel, which, at 47 bushels per acre, give the following remarkable results:—

White Wheat, per acre.	£	s.	d.	Red Wheat, per acre.	£	s.	d.
Grain.....	11	3	3	Grain	4	10	0
Straw	3	0	0	Straw	2	10	0
	£14	3	3		£7	0	0

It may be said with undoubted truth that there are plenty of worse crops of White Wheat and better crops of Red Wheat in this country, and we agree. But there are nothing like facts, and our object in a comparison of results in two extreme cases is obvious enough, and we have been careful to avoid over-statement in either case. One more fact should not be overlooked, and that is, that although closely pressed by foreign produce, home-grown Wheat still commands the highest price at Mark Lane.

The home farmer must always grow enough Wheat for home consumption, and if he be wise he will not make any reduction in the additional quantity he is accustomed to grow. Let him, however, see that every point of culture has due attention, and is done in the best way. Clean well-drained land, good seed of the best sort, and well-stirred fertile soil. If the land has not been enriched sufficiently by the ploughing in of green crops or folding, then give it a half-dressing of artificial manure at the time of sowing and the other half-dressing next February—quarter cwt. nitrate of potash, three-quarter cwt. nitrate of soda, quarter cwt. of superphosphate, quarter cwt. of ground coprolite, and quarter cwt. steamed bone flour. This is the correct quantity per acre for a half-dressing, each sort of manure being had separately, and then mixed under the farmer's own supervision at the farm. When the mixing is done weigh off the quantity required for each field, put it in bags, and if not used at once set the bags apart from others with a label bearing the name of the field for which it is to be used. Drill the seed corn,

follow with the manure mixture sown broadcast, and then pass the harrows over. Pay no attention to chatter of ignorant people about loss of nitrates, or overgrowth of straw from the use of nitrate of soda. Among really earnest thoughtful men such erroneous ideas have long been set aside, for the simple reason that they were proved—mark the term—proved to be wrong. If we are to have a full strong development of straw and grain among our corn the plant must have full sustenance from the time of seed-germination, and, therefore, the soil must be sufficiently stored with fertility. Do not hesitate to sow Wheat or any other corn twice or more in succession upon the same piece of land if you have only taken care to restore to it the elements of fertility withdrawn from it by the last crop. That is a point of good culture always to be remembered; but, then, in order to do it well and in the right way we must know all about the soil, the crop, and the manure we use. Again we say, regard the soil as a medium for the conveyance of food to plants—a medium from which the store of food is to be absorbed, and to which it can be restored just as often as we know it to be necessary.

WORK ON THE HOME FARM.

The Flock.—In about another week the tups will be withdrawn from the breeding flock, and two or three of the best of them will then be sent to the ewe lambs at two off farms. In view of this the lambs have had plenty of dry as well as green food for some months, in order to bring them forward in growth and strength for breeding thus early. We are bound now to make every stroke tell, and although sheep have fallen much in price we must keep on doing our best with the flock, and we have not yet lost faith in lambs as a profitable investment. For some weeks past the sheep have been withdrawn from the grass land and been on the Clover layers, and the rain has induced so free a growth on the meadows that we have an abundance of food on all the good meadows. Some poor land will soon have old sheep put upon it in folds to help the grass for another season. Old sheep, with plenty of nutritious dry food, doing so much good as to render the soil rich in fertility for another year. We have a considerable number of such sheep either withdrawn from the flock or purchased for folding on poor land, and some of them are almost ready for the butcher, our plan being to withdraw them in hatches from the folds as they become fairly plump. Many old ewes were kept so late with the lambs this year as to be left in wretched plight, and they were then pushed into the market and sold for a trifle, owing to the scarcity of food which the drought caused. To purchase such old sheep to fatten for the butcher is certainly a rash proceeding if done for that alone; but for folding on poor land the plan answers very well—better, perhaps, than anything else we can do for the improvement of poor grass land.

Arable Land.—So busy have we been upon the land that it has been no easy matter to spare horses to cart corn to market. Ploughing and Wheat-sowing is being pushed on as fast as possible, and we hope now to soon turn our attention to the root crops. Mangolds have made a good late growth, and the crop has gained considerably in bulk. This valuable supply of roots will be carefully stored, and the Carrots will be taken to one of the outbuildings for immediate use among the horses and dairy cows. Much of the Mangold field will be ploughed for Wheat, which always answers well after Mangold, plenty of manure remaining in the soil to insure a full Wheat crop. We have taken especial care in the selection of our seed corn for autumn sowing as an important means to success.

REMARKS.

4th.—Fine, but slight shower about 5.50 P.M.

5th.—Dull and drizzly all day.

6th.—Fine bright morning, very wet afternoon, and in night.

7th.—Fine and bright; fine sunset.

8th.—Dull showery morning; fine and bright most of afternoon; showers in late evening.

9th.—Fine and bright.

10th.—Rain in small hours, and till 10 A.M.; damp afterwards.

Rainfall still above, and temperature below the average—in fact, the temperature has fallen almost without interruption since the middle of August, and has been almost always below the average.—G. J. SYMONS

THE HISTORY OF THE PEAR.

THE Pear Congress of the Royal Horticultural Society was opened yesterday (Wednesday) at Chiswick, and proved in all respects a worthy successor to the remarkable display of Apples which was provided at the same place two years ago. A report of the exhibits appears in another portion of this issue, but in view of the interest attaching to the important fruit so well represented in the Chiswick Gardens we give the following *résumé* of the chief points in its early history.

The Hebrews knew the Pear only in its wild state (Agas), but Homer places it among the fruits of the garden of Alcinous:—

"The branch here bends beneath the weighty Pear,
And verdant Olives flourish round the year.
The balmy spirit of the western gale,
Eternal breathes on fruits untaught to fail:
Each dropping Pear a following Pear supplies,
On Apples, Apples, Figs on Figs arise:
The same mild season gives the blooms to blow,
The buds to harden, and the fruits to grow."

Beyond the fact of the ancient Greeks having this fruit in cultivation we know nothing; but when we descend a little lower in the order of time we find among the early Romans not only considerable knowledge of its cultivation, but that they had many varieties, distinguished by names which told of their quality, their place of birth, or their first owners. Thus Cato, who lived half a century before the birth of our Saviour, enumerates, as the most excellent of Pears, the Voleman, Anicianan, and Sementivan; at the same time characterising the time when winter had quite departed, as being "when the Pear begins to blossom."

Cato also gives directions for raising the Pear from seed and giving them a shelter, which might be adopted even here advantageously. He says: "Sow it very early in the spring. Make the beds 5 feet wide; lay in some pulverised manure; spread it and break the clods; make the bed level, or rather a little hollow; then sow the seed thick, like Flax, sift the earth over it an inch thick; level the earth with a tablet or with your feet; fix poles around, lay perches on them, and lay on sprays or hurdles made of the Fig tree, which may keep off the cold and the heat. Make them so that a man may be able to walk under them. Weed the beds often; as soon as the beds begin to grow take them up, for if you pluck up hardy weeds you will take up the Pears with them."

Columella, Pliny, and others are still more copious in their lists of Pears; and some modern fruitists have endeavoured to identify these with varieties at present known to orchardists. Without expressing any assent to these identifications, yet we think they are not without interest; and we would not have the man for our friend who does not care to know that he is partaking of fruit descended from trees of which Pliny, Cicero, Varro, Columella, and Virgil may have enjoyed the produce.

To aid our readers in the enjoyment of this pleasant

possibility we will trace out some particulars which Dalechamp and others have suggested upon this subject.

Columella says: "We must be careful to plant our orchards with the most excellent and fruitful Pears. They are these:" Crustumina.—This was so called from Crustuminum, in Hetruria, where it was most cultivated. Pliny says it was of most grateful flavour; and Servius says it was small and partly red. Supposed to be our Petit Blanquet, Little Blanket. Regia, or Royal.—Pliny says its stalk was so short that it grew close to the branch, was oblong in form and green in colour. Dalechamp considers it to be the Carmaignole. Signina.—So named from Signia, in Italy. Pliny says it was by some, from its appearance, called Testacea, or Brick-coloured. Dalechamp thinks it is the Cat Pear (Poire Chat). Superba.—It is small, says Pliny, but it is the earliest. Hardouin and Dalechamp agree that it is our Little Muscat. Ordeacea, or Barley Pear; because, says Pliny, it was ripe in Barley harvest. It is thought to be our St. John's Pear, or Amire Joannet. Favoniana.—Pliny says it was red, and a little larger than the Superba. Dalechamp and Hardouin think it is our Great Muscat. Lateritana.—Probably from its brick-red colour; is supposed to be the Poire Prévost, or Provost Pear. Dolabelliana was named after a Roman citizen, and distinguished for its excessively long stalk. Dalechamp thinks it is our Musette d'Automne (Autumn Musette), or Pastorale. Venorea, or Venus Pear.—So called, says Pliny, from the beauty of its colours. Dalechamp says it is the Poire Acciole. Onychina, the Onyx Pear, from its purple tints. Dalechamp thinks it is the Cuisse Madame.

We might extend this catalogue twofold, but, after remarking that though the Romans paid such attention to the Pear, it is entirely neglected by the degenerate race now occupying the territory of the Seven Hills, we will next pass on to the consideration of what has been done to improve this fruit in more modern times.

To show further the knowledge of Pear culture possessed by the Romans we shall not stop to gather together the fragments of information sustaining our opinion, which we find scattered through the works of Cato, Columella, and Varro, but will turn at once to what is said by the brothers Gordian and Maximus Quintilius. They flourished in the second century, and in fragments of their writings, in the "Libri xx. Geoponicorum," we find that they recommend for the Pear a cool and damp soil, adding that if the fruit is gritty the soil should be improved and well watered—a recommendation also given by Palladius. Diophanes, who wrote before Columella, Varro, and Pliny, for they quote from his writings, directs that Pears must be planted in a mild situation; that to promote fruitfulness some of the main roots should be split, and the fissure kept open by a wooden wedge; and that if languid they should be manured with the refuse of the wine-press. The Romans had their Mr. Rivers, or advocate for dwarf Pears, for Tarentinus directs them to be grafted on the Quince (*Malum cydonia*). We might enlarge our extracts demonstrating that they knew how to propagate the Pear by cuttings, a lost art, but recently said to be re-discovered; however, we have quoted enough to justify our statement, and will at once proceed to examine what our earliest English herbal writer, Dr. Turner, says about this fruit tree.

In the second part of his "Complete Herbal," published in 1562, he remarks, "We have many kinds of garden Pears with us in England, and some kinds better than ever I saw in Germany for wholesomeness; and some in Germany more pleasant and greater than ever I saw in England. I have read in no old writer so many kinds of Pears as I read of in Pliny, whereof I will show certain Latin names, and compare them with our English Pears and Dutch Pears as well as I can. Pyra superba—that is to say, Proud Pears, are little, and soonest ripe; and these are called in Cambridge, Midsummer Pears. Falerna pyra have their name, saith Pliny

because they be full of juice. These are called, in some places, Watery Pears or Moist Pears. Dolobelliana are the Pears that have long footstalks. I remember not how they be named in England. Volema, whereof Virgil makes mention in the second book of his Georgicks. These, because they are very heavy, as Virgil sheweth, and very great, as their name betokeneth, for they seem to have their name of vola—that is, the hollow place or loof of a man's hand, because they be as big as a man can grip in the palm or loof of his hand. These are commonly called in English, Wardens, if they have a binding and be red when they are roasted, and indure unto March or February. It appeareth that they have their name of long keeping; for Warden, in Dutch, from whence our English came, is to keep. Serotina pyra are they that hang upon their mother until winter, and were ripe with the frost. These are partly our Wardens, and partly other long-during Pears, which are called in Dutch, Winter Birnen; and they may be well called in English, Winter Pears."

Next in order of time came Gerarde, who says—"The stock, or kindred of Pears are not to be numbered; every country hath its peculiar fruit. Myself knows one curious in grafting and planting of fruits, who hath in one piece of ground at the point of threescore sundry sorts of Pears, and those exceeding good, not doubting but if his mind had been to seek after multitudes he might have gotten together the like number of those of worse kinds." Johnson has altered Gerarde's arrangement of the Pears he specified, and given the following as the ancient titles, and our Pears which are synonymous. Whether correct or not in that respect, they certainly show eight varieties then known in our gardens, and some of which are still surviving. 1, *Pyrus superba* (Katherine Pear); 2, *Pyrus præcocia* (Jenneting Pear); 3, *Pyrus Jacobæa* (St. James's Pear); 4, *Pyrus regale* (Pear Royal); 5, *Pyrus Palatinum* (Bergamot Pear); 6, *Pyrus Sydonia* (Quince Pear); 7, *Pyrus episcopata* (Bishop's Pear); 8, *Pyrus hyemale* (Winter Pear). "All these," says Gerarde, "and many more, and those most rare and good, are growing in the grounds of Master Richard Pointer, a most cunning and curious grafter and planter of all manner of rare fruits, dwelling in a small village near London called Twicknam; and also in the ground of an excellent grafter and painful planter, Mr. Henry Banbury of Touthill Street, near Westminster; and likewise in the ground of a diligent and most affectionate lover of plants, Mr. Warner, near Horsey-down, by London." It would not avail much now to seek for Pear trees either in Tothill Street or Horsleydown!

Descending a few years later we find, in some degree from our increased intercourse with France, but still more from the improvement in our garden literature, that we have much fuller and certain information relative to the varieties then known. Many of them are among our most common Pears now cultivated. Thus Parkinson, in his "*Paradisi in sole Paradisus terrestris*," published in 1629, mentions among others the Bon Chrétien, Bergamot, Green Chesill, Catherine, Windsor, and "the Peare of Jerusalem, which being baked, is as red as the Red Warden, whereof Master William Ward of Essex has assured me, who is the chief keeper of the King's Granary at Whitehall."

Parkinson was certainly not a total abstinent from chirpy liquor, for he says, "The Perry made of Choke Peares, notwithstanding the harshnesse, the evill taste, both of the fruit when it is greene, and also of the juyce when it is new made, doth yet after a few moneths become as milde and pleasant as wine, and will hardly bee knowne by the sight or taste from it; this hath beene found true by often experience, and, therefore, wee may admire the goodnesse of God, that hath given such facility to so wilde fruits, altogether thought uselesse, to become usefull, and apply the benefit thereof both to the comfort of our soules and bodies."

Some old and well authenticated varieties are still in cultivation, but the majority of those generally grown have been raised or introduced during the present century. As

instances of a few of those that made their appearance before that time, and are still found in gardens, we may cite the following. The Achan, probably introduced to Scotland from Norway at an early period, but the actual date is uncertain. The Amadotte was also early introduced to England from France. Angelique de Bordeaux was brought from France about 1708. Autumn Bergamot has been doubtfully supposed to date from the time of Julius Cæsar. Barland was grown in Herefordshire as early as 1674. Besi d'Héry was discovered early in the seventeenth century, in the forest of Héry in Brittany. Beurré Rance was raised at Mons in Hainault in 1762. The Catherine Pear was mentioned by Parkinson in 1629. Chaumontel was discovered in the Château Chaumontel, on the road from Amiens to Paris in 1685. Gansel's Bergamot was known before 1753. Gros Rousselet was mentioned by Rea as the Great Russet of Rennes in 1665. The Longueville is thought to have been brought over to Scotland from France in the fifteenth century. Louise Bonne originated at Avranches in 1728. Passe Colmar is of Belgian origin, having been obtained at Mons in 1758. St. Germain is an old French Pear known about 1690. The Seckle is of American origin, and was in cultivation before 1765. Uvedale's St. Germain was raised in England towards the close of the seventeenth century, and the Windsor Pear was known as early as 1563.

Probably some of these patriarchs of the Pear world will be found amongst the numerous exhibits at Chiswick, as well as the very abundant, handsome, and fine quality varieties of later origin.

ANNUAL MEETING OF THE YORKSHIRE ASSOCIATION OF HORTICULTURISTS.

ADDRESS BY THE REV F. D. HORNER.

[At the last annual meeting of the above Association, held at the rooms of the Paxton Society, Wakefield, the Rev. F. D. Horner delivered an interesting address upon the general objects of the Association, and this was supplemented by a lecture on the Auricula. We have been favoured with the MSS. of both these, and as they are of far more than local interest we present them to our readers.]

I ESTEEM it a great honour and feel it a great pleasure to be asked to take this part in the day's proceedings. If I am to stand before you as a sincere lover of flowers, then my heart does not condemn me, but if it is as one who is able to say all that should be said on such an occasion, then my knees tremble, and I think you might have found someone more capable. Feeling this, I begged our Secretary to call my address a short one. Perhaps that is not as plainly said of my lecture also, but I must ask you to understand it of that too.

The Auricula is a very favourite flower of mine, but lest over it, or the other branch of my subject, I should stray into too great lengthiness, I have taken the precaution to anchor myself, as it were, to the limits of this paper. An important feature of our evening's programme remains after I have spoken, and I wish to keep mindful of this.

Into whose mind the idea which we develope to-day first came as a germ of thought I do not know, but it was a happy thought. The Wakefield Paxton Society, in having taken the first action, may be said to have germinated the idea as far as the seed leaf. That, we all know, is an early crisis in the life of a young plant, and it must soon lay hold of wider stores and stronger elements, and seize the opportunities and means of growth into maturer life that come within its reach. So our seedling idea, finding congenial elements in other horticultural societies of our county, is brought well into the rough leaf of its existence to-day, and now by combined harmonious action on the part of all, we hope, and have good faith in our hope, that the project will put forth branch and blossom, and bear much fruit.

These societies, and especially such strong combinations of their varied strength and experience as we inaugurate to-day, cannot but tend to spread horticultural knowledge and fervour. It is a friendly combination of practical men, and the aggregate force of it will be great. I hope we shall all think much of its intent and inherent powers. It will be held together by that bond of brotherhood which is at once so strong, yet gentle, among lovers of flowers. That love is very innocent, and it is one of the most natural of our affections. It speaks well, it is some relic of bright things in erring human nature to know that one pure taste and love left in it is natural to it, born with it,

and not destroyed. Children learn to love flowers before they learn to understand evil. The country child's first toys are flowers, the town child's chief wonderment outside his dingy surroundings of streets and paving stones are flowers. What a sign of a pure love and taste triumphant was that poor crippled child's sick-room window, that had in it a Hyacinth blooming in an old blacking bottle. I think it was Charles Dickens who noticed this, and he knew the little watcher and sufferer needed no more sweet comfort of flowers, because next spring the child's Hyacinth was not there.

Well, my friends, the bond that draws us now together is that of an early implanted natural affection. This love of flowers is first pure then peaceable; let us keep it so, and then we shall not fail of all the good we seek. Each separate society in our Association does not lose its own identity, its own marked line of interest, its own particular colouring, by joining in one at this point, any more than do the side streams that here and there along the watercourse of a river join in on one common journey to the great sea lose their names and qualities where they are yet separate becks and rivulets. But, like as many tributaries make a river navigable at last, and of untold value not only to a district, but to a whole nation, so do we hope that the Yorkshire Association, which, riverlike, gathers from the wide horticultural area of the grand county of which we Yorkshiremen are so proud, may bring and carry forth results that shall be marked, and broad and valuable to the whole pursuit and science of floriculture.

To change the figure, and speaking, of course, still figuratively, we shall keep one another warm, brace each other up, help and expand each other's views. This nearer view will make us look more narrowly at one another, and we shall find our brethren not so narrow as perhaps we thought. If other of the societies that become kin to-day are like the Paxton Society of Wakefield, then the florist element will be appreciable. I suppose I may say it is a rare, I am sure I may say it is a useful element; I hope it will increase. I daresay I am put down as a specialist and an extremist, and so I may as well say that the florist element cannot be overdone; I believe its essence really pervades and influences further and wider than is thought. One truth our horticultural brethren will learn from us florists is this, that the love and intimate observation which the culture of florists' flowers beget, do not restrict and blunt floral sympathies, but enlarge them. It is just those who go most minutely and strictly into any pursuit or science who have large heart and eye for all. Such devotion is expansive. I have never met any who loved a wild flower so well as brother florists, never any who had a fuller appreciation of all than those who were supposed to care for only one or more strict florist's flowers.

I hope many florists will join this Association, and that many others who have joined will become florists. I hope that every wholesome leaven brought in may work throughout the whole; and, speaking of my brother florists, I think I may say that the general body will find that the particular men the florist specialists have so large sympathy with all floriculture, that they gladly join this Association through its tributary branches, as a welcome means of letting their whole heart go free. None of us can go beyond our opportunities, few of us can find that our means and opportunities are equal to the breadth of our desires, the depth of our floral love, the height of our aspirations. Where we cannot have full scope for these implanted and aroused instincts, what so near and cheering as the advantages of such an Association as this? The very objects of it speak of the wealth we can enjoy in common, the good which we can give and take, according to the varied store in our different treasuries of literature, knowledge, and experience. If we could say that we felt no interest in the objects of our united action as laid before us now, it would be saying we did not value the science of our art, and were content to be more or less solitary and shallow pursuers of it, each one buying his own experience and selling it not.

But where knowledge is wide standards are high, and success is greater in the sense of being more highly prized, but I can remember the time when a secret was the supposed way of success. The time, use, and fruition of knowledge, which is the imparting of it, was not always understood and felt. Now we walk in a fairer truer light, and the endeavour, one with another, is to see not how little we have to learn, and how little we need impart, but how much and how thoroughly.

Of course, exhibitions are instructive; there we see plants and flowers and fruits in such calm and finished perfection, that they seem to have known nothing of the roughness, suffering, and sorrow in which the whole creation, alike of things that feel and things that cannot, groan together in this sad world, and we know that the competition is a sharp spur to effort, and

where competition is healthy and fair it is a life-giving stimulus. But something more besides these contests is required to bring the full life into play, something more than conquests won and disappointments borne with silent grace and fortitude, and one thing more is this broad, brave, and helpful fellowship of friends and fellow labourers. I think our Association is meant to be, and will prove to be, a vital organ of the body floricultural.

If flower shows are the outward features, so fair and varied in their beauty that they seem like something belonging to that old first garden, of which but the name remains to us now, then this new community in which we enrol ourselves will be the power and function that will send the pulse and glow of healthy life throughout. I think I am not too sanguine in anticipating and hoping and prophesying this. I at least take no credit to myself for far-sightedness. I do not consider that I am looking through spectacles rose-tinted by the warmth and enthusiasm of this day's inauguration festival. No, I am looking with naked eye, and I think yours will be as single as mine.

The time has gone by for regarding a brother horticulturist merely as somebody set up to be bowled over at a show, and all the better victim for being as raw and unenlightened and unhelped as possible. What I may call the cold heartless competitions of shows is passing away, or is gone. We meet at many by times, and have wayside intercourse. Men of a fancy, a taste, a pursuit of recreation, are not content to meet as strangers, and as strangers part, they know there is always something valuable in that which helps to an interchange of knowledge, and which gives a body of men coherence, that will be the province of our united horticultural forces. If the example is new, let us keep it good and true, and then the spread of it will be one more bright feature in the prospects of horticulture.

(To be continued.)

NOTES ON GRAPES.

TRENTHAM BLACK.—This may be seen in the early house at Wrotham Park in company with Black Hamburg and Black Prince. The bunches are late in showing and are not very handsome at any period of growth. The berries set somewhat irregularly, but with careful thinning a fairly good-looking bunch can be grown. The shape of berry (if my memory serves me right) resembles Black Prince. It is a good grower, assumes a beautiful colour, and in flavour it is first rate.

MADRESFIELD COURT.—This is a grand Grape, and I am glad to say I have found out the way to grow it. Seven years ago I lifted a seven-year-old Vine out of the late house and put it at the warmest end of the second house, and so pleased are my employers with it that I am instructed to plant more of it in preference to Black Hamburg. I keep the top ventilators open a little at all times, and also in front when the berries are swelling, and have no trouble to finish it without cracking. The only fault I find is that it does not keep so well as Mrs. Pince, Alicante, and Lady Downe's.—G. MERRITT.

JOHN DOWNIE.—I had a young Vine for trial from Mr. Downie of the Vine bearing his name, with the view of proving its worth and its distinctive character. It was planted in a house to be used chiefly for the growth of Muscats along with a few other black sorts. Within a year or so, as is my usual practice, I took from five to ten bunches from each supernumerary Vine. John Downie and Alnwick Seedling appeared to be identical in appearance of foliage, wood, strength of growth, appearance of fruit, and flavour. This year (being their second season of fruiting) I can discover no difference between them. Mentioning the fact to Mr. Downie when he paid a visit here last summer, he stated that he believes a mistake has occurred in sending out this Vine, as the original variety seemed much more like Gros Colman than Alnwick Seedling, and so I think, judging from samples of each which I saw exhibited together.—M. TEMPLE, *Carron House*

JUDGES AND THEIR WORK.

It would seem from the remarks of "A Kitchen Gardener," page 203, that judges are not much better chosen in his district than in this, and I am sorry to say there are other places where similar blunders are continually being made.

In the county town here (Midland) there are five shows held during the year, which are well patronised by the public, yet there are but few examples worth going to see, as many of the best exhibitors do not show now. There are four judges, who are nearly always chosen for each of these shows; one is superintendent of the cemetery, another of the public park, another is a florist, and the other is a clergyman who grows Roses and Pansies well, but never attempts to grow anything else.

What practical gardener would exhibit fruit and vegetables there and expect justice? Why are they chosen? Because they are each well

known in their separate lines of business, yet many appear surprised that showing is on the wane in the neighbourhood.—J. L. B.

THE PRIMULAS.

(Continued from page 313.)

P. CLUSIANA, *Tsch.*—Though as yet rare in gardens this is the most beautiful of all the Tyrolean Primroses, and perhaps the easiest managed in cultivation. Through the early spring months it is unsurpassed by any hardy flower, its firm-textured flowers resisting almost all kinds of weather. The flowers are larger if anything than our Alpine Auriculas and produced with equal profusion. It thrives best on a west exposure in a rich soil to which plenty of limestone has been added. It must not lack water during the growing season, and if planted on a slope it is rarely if ever damaged by moisture during winter. The position should be exposed, and be such as to allow the plant to get the midday and afternoon sun. A plant nearly related to the above has been lately introduced from the Continent under the name of *P. Churchilli* or *admontensis*. It seems to be a hybrid like *P. super-Clusiana*. The leaves are smaller, narrower, and partake a little of the glossy

Fig. 55.—*Primula Clusiana* (Reichenbach's "Icones Plantarum").

P. spectabilis. It is, however, inferior as a garden plant to the type, and only desirable for variety.

P. Clusiana grows from 6 to 9 inches in height, the scape bearing a head of flowers numbering from five to ten, each about an inch in diameter, of a very bright rose colour. Leaves broadly ovate, slightly pubescent, prominent on the margins, which are slightly indented from where the leaf begins to taper to the petiole. Sepals ovate, very blunt, sparingly hairy. It flowers from the end of March until May. It ripens seed freely, and is also readily increased by division.

P. CORTUSOIDES, *L.*—The Cortusa-leaved Primrose is said to have been first introduced to this country about the year 1796 by Messrs. Lee & Kennedy, nurserymen at Hammersmith. It was much admired at that time, when something under a dozen Primulas were all in general cultivation. It has up to the present time held its own ground in the popular estimation, and in some of its forms, including the *amœna* varieties, bids fair to be the Primrose of the future. The remark of Linnæus that it has the foliage of a Cortusa with the flowers of the *Aretia vitalliana* holds good now, the typical form grown in gardens having altered little in all these years. Although perfectly hardy with us it should never be planted in exposed places, as, owing to its tall habit of growth and fine-textured

flowers, it invariably suffers from cold winds if not from late frosts, &c. A sunny sheltered nook in the rockery suits it well close to low shrubs or stones, but with a full exposure to the south or west. It grows best in rich light soil kept free and open with small pebbles, &c. Good drainage is of great importance to the successful growth of this plant, and especially during the resting season. It is from 6 inches to a foot in height, bearing a loose capitate head of handsome rose-coloured flowers of various shades, deeply cut, and about an inch in diameter. The leaves, which die during winter, leaving the crown exposed in the form of a ball, are ovate in outline, bluntly and irregularly toothed, having a cordate base, the edges being involute when in a young state. It has given rise to numerous varieties, the *amœna* section being treated under *P. Sieboldi*. It flowers May and June, and is a native of Siberia, increased by division or seed, the latter being best, as they make the freest flowering plants.

P. CRIDALENSIS, *Hort.*—This is supposed to be a hybrid between *P. tyrolensis* × *Wulfeniana*, and from the appearance of the plant, both habit and leaves, there is every reason to believe this is correct. It was introduced by Mr. Backhouse of York. It is growing well on an east exposure, but seems to suffer from drought more than either of its parents. Leaves ovate, again broadening to the base of the petiole, slightly ciliated, and rough on the upper surface. We have never seen this plant in flower.

P. DAONENSIS, *Leby.*—A name given in 1854 denoting one of its localities, and preferable to *P. œnensis*, *Thom.*, which, though given two years earlier (1852), is altogether unmeaning compared with the other. It is now being generally adopted, and will no doubt in time take the place of the other. *P. daonensis* is a very pretty little plant, never attaining more than an inch or so in height; but as it seems to be variable it may be more robust in some of its forms. It was one of the plants brought home by Mr. Maw from the Lombardy Alps in 1875, at that time considered a rarity and much sought after. It forms little glutinous rosettes as close to the ground as *P. minima*. The leaves are wedge-shaped or cuneate, and may be compared to a lawn tennis bat, the margins of the upper half bluntly serrated and thickly studded with glandular hairs. The large pale rose-coloured flowers are very handsome, their beauty being increased by the lovely silvery white eye. It thrives best on limestone, the plants requiring to be firmly wedged between them. It likes plenty of sun, a south-eastern exposure being the most suitable. It flowers in May and June. Native of the Tyrol, Eastern Swiss Alps, &c., from 6500 to about 1000 feet above the sea level. Syn., *P. cadinensis*, *Hort.*, a garden form with longer and narrower leaves; *P. œnensis*, *Thom.*; *P. Stelviana*, *Vulp.*; *P. hirsuta*, *Rech.*

P. DENTICULATA, *Smith.*—For the introduction of the purple Nepal Cowslip we are indebted to the enterprising firm of Messrs. Veitch of Chelsea. This is also one of the plants that have not got quite used to our climate, either throwing up its handsome heads of flowers too late in the season or too early before the severe frosts and cutting east winds have ceased. In a few places where it can be well sheltered without the exclusion of light it flowers freely and shows an extremely vigorous habit. At Wisley, the experimental garden of G. F. Wilson, Esq., I saw large patches of them growing in the wood. They had plenty of the needful light, and were well sheltered on all sides by the thick brushwood, and overhead with the forest trees. I had also the pleasure of seeing the flowers produced in the spring well-formed heads almost as large as a cricket ball and of a superb colour. Of course there is not such a wood in every garden, but all who wish to grow a really valuable plant will not be long in finding a position suitable to its requirements. Whatever situation be chosen it must be one well sheltered from the east winds, for even in the south of England in the open border the flowers never open, the flower heads are distorted, and the plant rendered useless. It does not seem to be a very good perennial even where it succeeds, and after a year or two seems to lose energy and deteriorate. My plan is to lift the plants every second year, divide them as small as possible and replant; the result is renewed vigour, and a greater number of larger flowers. I have also seen this used effectively in large conservatories, planted as an edging with *P. japonica*, and attaining remarkable dimensions, with both flowers and foliage.

It usually grows about a foot high, throwing up numerous stout flower stalks, which are terminated with large heads of purple flowers in various shades. The flowers are closely packed together, averaging half an inch in diameter. Leaves oblong, spatulate, about 6 inches long, wavy, wrinkled; veins reticulated, and sharply toothed margins; the petioles are generally of a reddish colour, peculiar to Indian species. It has given rise to numerous varieties, among the most distinct being *B. cashmeriana*, which grows larger than the type, and with dark lilac flowers, very distinct and beautiful. *Henryi*, perhaps a robust form of the variety *pulcherrima*, which may easily be distinguished by the presence of meal dust; it is a

much handsomer plant than the type, and in all ways preferable. *Amabilis*, lately introduced by Max Leichtlin of Baden-Baden, is quite distinct, and very showy; the varieties *nana* and *paucifolia*, both of which are distinct, do not appear to be in cultivation. All the above plants flower from early March until June, and where well sheltered form really handsome groups. The flowers last a considerable time in water, and will be found very useful in a cut state. Syn. of type, *P. Hoffmeisteri*, *Klots*. Natives of the Himalayas.—D.

(To be continued.)

JUDGING CUCUMBERS.

MUCH has been written lately about judging Grapes at our exhibitions, and some good hints have been thrown out to judges and others on the subject. While attending flower shows in different parts of the country my attention has been drawn repeatedly to the way in which Cucumbers are generally judged, and I have often wondered why the subject has not been taken up long ago. If I understand rightly, the prizes offered by societies are meant to encourage the cultivation of the most useful varieties; but, as a rule, the prizes are given to long unproductive varieties that have no merit whatever but their length to recommend them. I have been often asked, and by competent gardeners too, "Why it was that judges encouraged the cultivation of these by giving them prizes, as they were unprofitable either for market or for private use?" I had to confess that I did not know myself, but that I had seen them marked in seedsmen's catalogues as being good varieties for showing, and that, I believed, was all they were good for, as it would not pay to grow them for market nor for private use, when there were so many good prolific varieties in cultivation—varieties that yield ten Cucumbers, from 12 to 16 inches in length, of the best quality, for every one that those monster long guns produce. I am fully convinced that the majority of Cucumber growers would give their verdict in favour of the prizes being given to Cucumbers from 12 to 20 inches in length. I would like to know your practical correspondent "Thinker's" opinion on the subject.—EUPHRASIA.

GARDENS NORTH AND SOUTH.

ON page 296, the issue of the 1st inst., reference was made to the condition of gardens as influenced by the great heat and extreme drought that so long prevailed in the south of England, and to the comparative freshness and consequently greater productiveness of gardens two hundred miles northwards. The difference that existed in those respects could not be appreciated except by travelling direct from one part of the country to another, and this I did. In Sussex, for instance, and it was the same in hundreds of gardens in the southern counties, it was found practically impossible to raise Turnips; in Lincolnshire and Yorkshire the fields were packed with them, and so luxuriant were they that on some highly farmed land where the crop was in rows 2 feet apart the growth overlapped the spaces completely. Nothing could better indicate the character of the season in the respective localities, and northern gardeners have had a "better time" than their southern brethren in distress during the summer that has now closed.

Even in the lowlands of Essex and the Fens of Cambridgeshire, so far as could be judged from the Great Eastern express on its way from London to Doncaster, vegetation appeared to be more exhausted than on the higher lands further north, where showers had been more prevalent and the sun consequently less continuously scorching.

FARMERS' GARDENS—ROSES.

In the garden of one of the best farmers in England, Mr. Ismay Fisher, a tenant on the estate of Mr. Sutton Nelthorpe, in North Lincolnshire, beds of Asters far surpassed any I had seen in the south, and if Messrs. Sutton of Reading could have seen the products of their seed they would have been satisfied with the manner in which the excellence of the varieties was displayed. This garden, too, is noted for Roses. Not only do the blooms "take the lead" at local shows, but Mr. Fisher has as one of his possessions a silver medal of the National Rose Society, won at Manchester last July with a magnificent bloom of Lady Mary Fitzwilliam as the best H.P. in the amateurs' classes; indeed, good judges have stated it as their opinion that a finer bloom was not seen during the season. In the chief open class at Hull, in which some of the foremost rosarians entered, though all of them did not compete when they saw what they had to contend against, Mr. Fisher's Roses excelled all others. He does not grow many, possibly not more than 200 plants, but grows them well. Fewer varieties and more of each of those that flourish there will be his future policy, dividing those that are found best adapted to rather light soil from others that prefer strong, and planting them accordingly. This, it will be conceded, is a practical method and can scarcely fail to have a satisfactory result. The grower of these Roses, as may be imagined, is not one of those persons who muddle along in one of those paradisaical "small holdings" in which the so-called "farmer's" wife boasted they kept a "hen and things." Neither is his farm so unwieldy that he cannot do full justice to it, hence by high culture he places himself beyond the pale of "depression," enjoys a good social position, and can indulge in the delightful pursuit of growing Roses to any extent desired.

A COTTAGER'S ROSES—LARCH.

While on the subject of Roses a quick and profitable method of raising them that has been pursued for years by an industrious "son of toil" may

be mentioned. John Braiser "works in the woods" on the estate named; in fact, takes the practical lead in their management, and if he could write about Larch culture as well as he conducts it could tell how sandy and apparently almost barren tracts of land could be profitably occupied. Planting a hundred thousand trees a year has been part of his duties, and the thrifty plantations are a treat to see. There is "money in" Larch-growing as practised there and on land that is practically valueless for agricultural purposes. But to the Roses. This worthy woodman digs up Briars in the autumn and plants them in his well-tilled cottage garden. They root quickly and push strong shoots in the spring, ready for budding immediately buds can be found. This is early in June; they start growing at once, and often flower freely during the season. Three or four buds inserted in a stock form a good head by the autumn, and thus Rose trees are made and sold within twelve months from planting the Briars. This is quick work, and if the plants or trees did not give satisfaction customers would not be retained year after year.

FROST IN SUMMER—THE CZAR PLUM AND HESSLE PEAR.

In contrast with the heat that was so oppressive in the south may be mentioned a "nipping frost" that occurred a little further north in the same country early in August. One large, prosperous, and excellent farmer on the estate of the Earl of Yarborough had three acres of Potatoes cut down, and Scarlet Runners, where not sheltered, shared the same fate. In other fields I saw many Potatoes cut by frost, but not so seriously. Mr. Beaulab, the gentleman referred to, is a good gardener, apiarian, and entomologist, but gardening and orcharding are in their infancy in his new home; still he has in a young plantation of fruits discovered the value of the Czar Plum as an orchard standard, trees of it having "done better" than any others. This and the Victoria he considers two of the most useful and profitable varieties to grow. He is probably not far wrong, yet while the latter is well represented in the north the former is scarcely known. It is known in Kent, and is being extensively planted by the fruit farmers there, which is about the best testimonial a hardy fruit can have.

A Pear not much cultivated in the south is seen in numbers of gardens and orchards in the north—namely, the Hessel, and it is a question if there is a more reliable orchard variety in cultivation. The branches were borne down by their loads, and the fruit sells readily in the markets, as the quality is known to be good. The Hessel Pear is in use in October, but once in it is soon over. It is not at all uncommon for fifty pecks to be gathered from a tree, and if only sold at 6d. a peck, the crop is of more value than the ground which the tree occupies, as it is not of spreading habit. In the district in question one tree of the Hessel is worth more than three of Beurré de Capiaumont, which is esteemed as an orchard Pear in some localities.

APPLEBY HALL.

The description of Lord St. Oswald's Yorkshire seat, Nostell Priory, reminds me of calling at his lordship's Lincolnshire residence, Appleby Hall, a quaint old building, surrounded with fine trees and shrubs. There is an extensive lawn and pretty flower garden, and so far from the drought and heat checking the growth of grass and flowers, the beds were overflowing with luxuriant plants, and the mowing machine was in constant requisition. At the same time lawns in the south were "burnt up" and flowers could not grow for the want of moisture. The gardens at Appleby are admirably kept, and vegetable and fruit crops good both outside and in. Amongst the plants well grown under glass, *Posoqueria longiflora* is cherished; it resembles a vigorous *Toxicophlœa*, and is similarly fragrant. The curious and brilliant *Strelitzia regina* was in superb condition, and *Chrysanthemums* were so good that if disbudding were practised they would produce blooms of exhibition quality. Mr. Johnson is not only an industrious and competent gardener, but appears equally skilled as an apiarian. He is an adept at making hives and sections, secures an abundance of honey of the first quality, and is quite convinced that "bees pay when well managed." That he manages them well, and the garden too, is beyond a doubt.

POTATOES—THE JENSENIAN SYSTEM.

Much has been heard about the Jensenian system of Potato culture of late, as "invented" by a Danish professor as a preventive of the murrain. The plan has this year been tried at Chiswick, but the season has not been favourable for testing its merits. If, as I understand it, the method consists in dividing and partially bending back the growths and "crowning" the plants with soil directly over the roots, the plan has been in operation at Appleby for a quarter of a century, not as an experiment in the Hall gardens, but as a regular method of culture generally adopted in the parish. The plan was to place good sets a yard apart on the surface of the ground and cover them with soil dug from between them. As growths extended they were thinned, leaving about four of the best, these being opened out and "crowned." This crowning was continued at intervals till no more soil could be found. The plants were then on hillocks, with the growths hanging down and covering the sides. The object of the cultivators was to get a peck of Potatoes of 21 lbs. from each root or hillock, and the feat was occasionally accomplished, while the yield was invariably great, as it ought to be considering the labour involved; and what is more, and this supports Professor Jensen, when the murrain was raging furiously in the district in 1872 the Appleby crops were practically free, as I ascertained from the excellent clergyman of the parish, Mr. Cross, to whom I wrote for information at the time. I shall be glad to learn in what respect the Jensenian system differs from the method described, and which I saw extensively adopted in the parish

named thirty years ago. It is not much practised there now, if at all, but recourse would perhaps be had to it should wet summers come again, and with them a malignant outbreak of the Potato disease. Be that as it may, someone commenced the practice at Appleby that appears to be identified with a foreign name, and I am sufficiently patriotic to desire Englishmen to have the credit to which they may be entitled, even in a method of growing Potatoes.

OAKBROOK—SHARPE'S VICTOR POTATO—DESTROYING WASP NESTS.

Moving on I next found myself at Sheffield, and a passing call on Mr. Woodcock at Oakbrook enabled me to see how well he continues managing Mrs. Mark Firth's gardens, and also to note that there had been no parching summer there, and lawn-mowing, that lapsed in the south, was a weekly duty. The Royal trees, of which there are seven in the grounds, are making good progress, the specimens of Fisher's Golden Irish Yew, planted by the Prince and Princess of Wales a few years ago, sharing the honour with a pair at Chatsworth of being the finest in the country. Lapagerias, which are so well grown at Oakbrook, were commencing to expand. The Parsley-leaved Bramble was producing long clusters of its large black fruit, thrice the size of wild Brambles, and regarded as indispensable; and Sharpe's Victor Potato had just been lifted—as fine a lot of tubers as was ever seen, and mentioned here because the variety is described by Mr. Woodcock as the best early Potato he has ever grown in frames or outside, and others may like to know it. Mr. Woodcock had also a very fine lot of Chrysanthemums, but I was sorry to hear from Mr. B. Simonite that most plants on the north side of the town were cut to shreds by a hailstorm early in August.

Though the summer was not hot wasps' nests were numerous, and the easiest, cleanest, and quickest way of taking them may be mentioned. The agent employed is cyanide of potassium. Many persons know how effective this is, but numbers have not tried it. They may do so next year if they are troubled with the fruit-devouring pests. A strong nest was found, and in the daytime, when the wasps were busy, about a teaspoonful of the rough salt-like substance was placed on the end of a 3-foot latb and tipped into the entrance, that is all. No more wasps came out till dug out; but what about those that are not in? They return from their foraging expedition and go tumbling in never to come out again alive. We watched attentively for half an hour, and not one escaped. The nests are dug out the next morning, but if firmly blocked up it is difficult to conceive what more is needed, except baits for fishing or food for fowls, which eat the white fat "grubs" ravenously.

TO CHATSWORTH.

And now on we go over the hills to Chatsworth—a twelve-miles drive, than which it is not easy to imagine anything of the kind more delightful in summer; but the run from Callendar to Loch Katrine leaves nothing to be desired. I have yet to see the lakes of Killarney, but as both Mr. Burbidge and Mr. Murphy have invited me "over," I hope to be able someday to compare Irish with Scottish and English scenery. There are two routes from Sheffield to Chatsworth by coach, and persons who have not travelled by either of them, and should have the opportunity, should choose the one by Froggat Edge (if there is another "t" in the word those who know can add it, I am sure I do not). It is marvellously cheap, only costing 1s. 6d. The "Edge" is the abrupt termination of a range of hills, rent and riven as if by some Titanic force tearing the rocks asunder and spreading the ponderous masses on the slope as if they had been so many pebbles in the hands of a sportive child. This is the work of far past ages. The ruin, if it may be called so, is stupendous, and is as rugged and wild as the most romantic mind can imagine. It is on the left; and on the right, what a contrast! Below us and stretching far away is a smooth charming pastoral valley hiding itself here and there between the tree-clad hills, the twisting Derwent shimmering in the foreground. If there were nothing but this even the gardening tourist would be satisfied; but there is Chatsworth at the end of it, and from a gardener's point of view the assertion may be ventured that it was never better worth seeing than during the present year. No attempt will be made to describe it. A notebook is essential for that, and it would be filled; but as this was deliberately and, if you like, by "malice aforesaid," left at home, only a fringe of the great place will be touched, with the object mainly of directing attention to a delightful Water Lily that all should grow who can, and which many might succeed in doing if they tried without the convenience of such a luxury as will be alluded to, and which can only be possessed by the few.

VICTORIA REGIA HOUSE—NYMPHÆA DAUBENIANA.

Since its erection this splendid structure has always been one of the noble features of these princely gardens. This year it is no exception to the rule, having recently been thoroughly repaired and redecorated. At the time of my visit it presented a sight not easily forgotten. The centre tank, 36 feet in diameter, is occupied with the Victoria regia, which was planted late in April. It has now twenty leaves on, many of them 6 feet in diameter. Between forty and fifty flowers had then expanded, and there were many more to follow. The largest flower measured 12½ inches in diameter.

Round the edge of the large tank are planted many varieties of Nymphæas which flower freely during summer and autumn, and add much to the beauty of the house as well as proving most acceptable in supplying a great quantity of choice cut flowers. The variety Daubeniana is the most useful for the latter purpose, and might with advantage be more extensively grown in stoves, where its fragrant and beautiful flowers would be much appreciated. Mr. Thomas has kindly penned a few lines

on the cultivation of this variety, which will be found in another column. Another superb species is the new Nymphæa zanzibarensis, its large purple flowers with brilliant orange centre producing a rich effect among other choice Nymphæas, such as pure white dentata and the Carmine Devoniana. There are many other varieties of Nymphæas in this tank, but the above are the most popular and showy. In the side tanks (eight in number) are planted Nymphæas of various sorts, Nelumbiums, Thalia dealbata, Pontederias, Triana bogatensis, Ceratopteris thalictroides (the Water Fern), and other rare aquatic plants. The side of the house and the curbs round the tanks are occupied with ornamental plants, conspicuous among them being the Musa coccinea (true variety), flowering freely on plants potted from suckers this spring. Celosias are splendidly grown in this house, the abundance of light, heat, and humidity seeming to suit them admirably. Coleus also succeed well here. I do not remember having seen any better coloured before, and, what is unusual, they are allowed to flower, which they do freely—a dozen spikes on a plant, several of them measuring 18 inches long. The effect of these light blue flowers against the brilliant foliage of the Coleus is most charming.

The doorway and a portion of the sides of the house are festooned with climbers, such as Cobæa scandens variegata, Cissus discolor, Vitis gongyoloides, and the pillars are effectively clothed with Allamandas, Bougainvilleas, Clerodendrons, &c. A notice of this house would be incomplete without a mention of the superbly grown baskets of Achimenes, which have been grown there for many years past, suspended from the roof. They have charmed and surprised all who have had the privilege of seeing them. They have been as fine this year as usual, as will be admitted when it is stated they were complete floral halls, varying from 12 feet to 15 feet or more in circumference.

In other departments the Chatsworth Gardens will bear close inspection. Eighty-years-old last-autumn-lifted Vines were bearing a splendid crop. Pines have undergone a striking transformation, 130 handsome fruits then advancing for autumn and winter; the plant houses near the mansion being thoroughly restored, and their contents in excellent condition, while the kitchen garden was filled to overflowing with useful crops. Scarlet Runners, however, that were exhausted by heat in the south, the sun burning off the flowers, were so checked by cold at Chatsworth that they could scarcely produce any flowers and no crop of pods worth gathering. Gardens, then, have not been "burnt up" all over, and the reports of heat and drought with the consequent scarcity of vegetation in the south must have been almost regarded as exaggerations by some northerners; but they were not.—J. W.

EARLY PRUNING OF VINES.

I WISH we had a few more men like Mr. Iggulden, who would give us their experience when they strike out of the beaten track. We are so apt to follow another, without stopping to consider if it is the most practical course to pursue, until we either stumble over something accidentally, or someone points out a much more reasonable way. I am but a young man, yet I have considerably altered my method of cultivating many plants from what I was first taught, chiefly through reading the Journal.

I was very pleased to read Mr. Iggulden's remarks on early pruning of Vines, as I have been practising early pruning about six or seven years by shortening the laterals and sub-laterals a little every week, commencing about the 1st of September (according to the season and the ripeness of the fruit), until the laterals are shortened to the leaf next above the bunch, and the sub-laterals have been all removed up to the last two years. Since, then, I have left the three lowest on each lateral. Since doing so, I think I have had better bunches. Previously I used to pull off all the lower sub-laterals when they were quite young, about the time they were in flower, or thinning commences. I should like the opinion of Mr. Iggulden and others on this, Are these lowest sub-laterals better left on and pinched to one or two leaves, or taken off when quite young? —J. L. B.

THE meetings of the NATIONAL ROSE SOCIETY have been arranged for 1886. The Metropolitan Show will be held at South Kensington, July 6th, the Provincial Show at the Botanic Gardens, Birmingham, on July 15th. The following Rose show fixtures have also been announced—Farnham, June 30th; Reigate, July 1st; Tunbridge Wells, July 2nd; Eltham, July 3rd; Sutton, July 7th; Hitchin, July 8th; and Wirral, July 10th. These Societies are all affiliated to the National.

— WILLIAMS' ORCHID ALBUM for October contains plates of the undermentioned. SCHOMBURGKIA TIBICINIS, the noted Cowhorn Orchid of Honduras, which is remarkable for its large conical hollow pseud-

bulbs. It bears a great dense spike of crimson and purple flowers, not unlike some of the *Lælias*.

— AN excellent plate of the small-flowered *ONCIDIUM BRUNLEESIANUM* is also given. The flowers are about an inch in diameter and are borne on closely branching panicles; the sepals and petals are pale yellow with slightly darker bars; the lip is rich orange, with the fore part dark brown, a curious contrast. The species is a native of La Plata and was found with *Oncidium varicosum* on the Rio de la Plata.

— A DELICATE and pretty introduction from Brazil is *LÆLIA MEASURESIANA*, which was pure white sepals and petals, the lip slightly fringed rosy crimson with a yellow throat. It flowers in April and May lasting "three weeks in perfection," and was named in honour of R. H. Measures, Esq., Woodlands, Streatham.

— THOUGH little known *TRICHOGLOTTIS FASCIATA* is a pretty and curious species, which is of scandent habit and grows somewhat like a *Renanthera*. It bears racemes of flowers upon the stems, the sepals and petals being yellow barred with chestnut brown, and a three-lobed white lip. At a glance it is not unlike some of the *Odontoglossums*.

— THE series of articles communicated to this Journal during the present year on the HISTORY OF THE CHRYSANTHEMUM by Mr. Harman Payne have been embodied by the author into a neat treatise of thirty-seven pages. It is not necessary for us to point out the exhaustive yet concise manner in which the subject is treated, but we may venture to say there are few if any growers of the popular autumn flower that will not find something in the treatise that they did know before it was pointed out by the author; and we suspect very few of them will fail to possess this little work, in which so much historical information is compressed.

— THE "Journal des Roses" for October gives a coloured plate of ROSE SOUVENIR DE VICTOR HUGO, which, judging by the figure, is a pretty brightly coloured variety, somewhat of the *Homère* style. It is a Tea variety, and is said to have been obtained from Comtesse de Cabarthe crossed with *Regulus*, and was obtained by M. J. Bonnaire, Monplaisir, Lyon. The flowers are very neat in the bud, the petals pale yellow or buff, edged and deeply tinged on the upper surface with bright rosy red.

— MR. R. SILK, gardener to J. Abernethy, Esq., Whiteness, near Margate, writes:—"In the prize list of the fruit show on the 13th and 14th inst., at Kensington, my name was mis-spelled 'Sich.'"

— THE date of the SHEFFIELD CHRYSANTHEMUM SHOW has been changed from the 13th and 14th to the 20th and 21st of November, on the ground that the flowers are so late in the district that they could not be fairly represented on the date first named.

— WE learn that Mr. B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, has secured the contract for the FLORAL DECORATIONS AT THE GUILDHALL on Lord Mayor's Day, in open competition.

— MR. DAVID THOMSON, Drumlanrig Gardens, writes:—"The statement quoted from a northern contemporary about THE DRUMLANRIG WOODS is not correct, beyond the fact that an immense number, about 300,000 trees, were blown down nearly two years since. Great numbers have been sold to various parties, but probably only about one-third of them have been disposed of. It will take years to clear the woods, yet I am happy to say that a visitor who had never seen the forests would not miss the fallen trees, so vast is the extent over which they are strewn."

— THE troublesome *CHRYSANTHEMUM APHIS*, to which English growers have applied the name of "the American Flea," and concerning which we have had several letters the past week or two, is also occasioning much annoyance in the United States, whence it is said to have been imported to this country in plants or cuttings of new varieties. A correspondent of "Meehan's Magazine" writes—"Every purchase of Chrysanthemums brings us an army of this pest, but I have always succeeded in getting rid of them. My method is to watch the plants carefully every day and wash them in strong soapsuds. Tobacco soap is best, but any good soap will do, taking care to allow none to escape from the dish of suds, and follow up this treatment without intermission as long as any remain. Various insect remedies are said to keep down all these pests of the greenhouse, but that is not at all satisfactory, and calls for 'eternal vigilance.' When extermination is at all practicable it should be the result aimed at."

— MR. G. F. WILSON writes:—"The authorities of the *Graphic* sent down a good artist to make drawings of our EXPERIMENTAL GARDEN AT OAKWOOD, WISLEY. Would you oblige me by letting my gardening friends know that these will appear in the No. of Oct. 24th?"

— THE Council of the HACKNEY MICROSCOPICAL AND NATURAL HISTORY SOCIETY will hold a Fungus foray in Epping Forest on Saturday next, October 24th. The trains will leave Liverpool Street station at 10.9 A.M. for Chingford, and 2.10 P.M. for Loughton. The route will be through the Green Ride and High Beach to the "Robin Hood" by the early train, where the afternoon party from Loughton can join at from 3.15 to 3.45 P.M. Dr. M. C. Cooke, F.L.S., Worthington G. Smith, F.L.S., Mr. J. English, Dr. H. L. Wharton, F.L.S., E. M. Holmes, Rev. J. McCrombie, and George Massee, are expected to be present. Mr. Collis Wilmott, F.R.M.S., of the Triangle, Hackney, is the Hon. Secretary.

— A JAPANESE has discovered a process of making PAPER FROM SEAWEEDES. It is described as thick in texture, and owing to its transparency can be substituted for glass in windows, and when coloured makes an excellent imitation of stained glass.

— "It requires," says an American contemporary, "a great deal of labour to run a LARGE VINEYARD. The proprietor of a raisin vineyard of 400 acres at Fresno, California, employs a force of 120 men to pick the Grapes, and will require this large number for a period of three months. His pay-roll for that time will average 3500 dollars per month."

— MR. J. HAM, The Wren's Nest, Ashwood Bank, writes as follows respecting OUR MIGRATORY BIRDS:—"House martins are always the last to leave of our summer migrants. A few remained with us until Tuesday last. About forty broods have been reared here this summer. Swallows were noticed on Sunday, but not since. The redwings were here on Wednesday, nine days later than formerly noticed. A woodcock was seen near here at the beginning of the week."

— SINCE June our borders have had no finer plant than *ROSA RUGOSA*, with immense trusses of large, clear, brilliant rose-coloured flowers. The foliage is very handsome, but the hips are even more so, being produced in large clusters, and are of a brilliant crimson colour. They are very effective, rendering the plants beautiful in early autumn, and are useful for purposes of decoration. The white variety, *R. rugosa alba*, is not so free-growing, being more erect in habit, still it has been admired as much as the rose-coloured form. In the bud state the flowers are charming. Both ought to find a place in every garden, being suitable for the front of shrubbery borders, the herbaceous border, or the rockwork.

— MR. R. OWEN, Castle Hill, Maidenhead, has sent us a bloom of an extremely handsome DOUBLE IVY-LEAF PELARGONIUM, which is one of the best and brightest-coloured varieties we have seen. The flower sent was 2½ inches in diameter, very full, and of a peculiar rosy scarlet hue, with a glossy surface, which has a beautiful effect in a bright light.

— THE same correspondent also wishes us to state that he was awarded a vote of thanks by the National Chrysanthemum Society for cut blooms of Chrysanthemums shown at the recent meeting in the Westminster Aquarium.

— THE NEW ENGLAND CROP OF APPLES promises to be larger than last year, and there continues to be a large supply of Apples in the market, especially from western New York. For the week ending Sept. 26th, shipments of Apples to Great Britain were 279 barrels from Boston, 10,146 from New York, and 559 from Montreal, making the total for the week of 10,984 barrels. For the season, the shipments foot up 27,232 barrels, against 64,792 for the corresponding period of last year. The last sales in Glasgow range from 3½ to 4½ dollars per barrel. Green fruit was neglected. In Liverpool prices were about 25 cents per barrel lower.

— THE first monthly dinner and conversazione of the HORTICULTURAL CLUB for the winter session took place on Tuesday last at their rooms, 1, Henrietta Street, Covent Garden. There was a large attendance, including Mr. John Lee (Chairman), Professor Foster, Rev. F. H. Gall and H. Flintoff, Messrs. Deal, Geo. Paul, Druery, Cousens, Collins, Stunfels, &c. The following new members were elected.—Rev. W. Willis, Shirley, Croydon; Messrs. E. B. Lindsell, Hitchin; Arthur Turner, Slough; W. H. Williams, Salisbury; Herbert J. Cutbush, High-

gate; and Geo. Bunyard, Maidstone. Professor Foster opened an interesting discussion on the "Germination of Seeds," which was continued by Messrs. Geo. Paul, Druery, Cousens, &c. The thanks of the members present were given to Professor Foster for his kindness in introducing the subject, and for the interesting facts brought forward.

— THE British colonies include the richest and LARGEST FORESTS IN THE WORLD, extending over millions of square acres. In India alone about 60,000 square miles are afforested, and the forests of Canada, Australia, New Zealand, and Cape Colony are second to none in size and the variety and value of their productions. The acreage under timber in France, Germany, and Great Britain is small and constantly decreasing. Of the 20,000,000 square acres of Scotland only about 700,000 to 800,000 acres are woodland.

— MR. GEORGE AUGUSTUS SALA is contributing to the *Daily Telegraph* a series of articles descriptive of Australia, the majority being readable and freely written letters. In a recent one on Adelaide he makes, however, an amusing BOTANICAL BLUNDER. He states that—"The site was, less than fifty years ago, literally a swamp, intersected by numerous small creeks and overshadowed by the maleficent umbrageousness of the Mangrove. That gruesome plant is said to shriek when it is interfered with by man. How the Mangroves must have bellowed when the practical utilitarianism of the last generation of South Australian colonists built up a commodious haven and a thriving town out of this quagmire." Is it possible that this usually accurate writer can have confused the British Mandrake with the tropical Mangrove?

— IN the production of ROSE BLOOMS for OTTO OF ROSES no less than 145 towns and villages are concerned. Under favourable circumstances 2000 lbs. of Rose leaves will yield 1 lb. of the otto, whereas at other times it will take no less than 5000 lbs. weight of leaves to produce the same quantity. The area required to grow the Rose trees to produce such innumerable quantities of flowers covers large tracts of country, and in order to save loss by evaporation after picking small stills are erected in the open fields. It is the more necessary to have the apparatus close at hand, as all the flowers for the same reason are picked if possible before sunrise.

— THE fourth annual report of the NORTH OF SCOTLAND HORTICULTURAL ASSOCIATION contains a general report of the proceedings and several papers that have been read by the members during the past season, those on the education of young gardeners, the culture of the Chrysanthemum, and the culture of the Tomato being particularly good. The Association is making substantial progress, and now includes 258 members. The programme for the present season is as follows, the meetings taking place the third Friday in each month at 7 P.M., in the Young Men's Christian Institute, 198, Union Street, Aberdeen:—November 20th, "Climbing Plants;" James Cannon, East Seaton. "Dinner-table Decoration;" J. M'Kay, Westwood. December 18th, the Lessons and Experiments of the Year. 1886.—January 15th, "Should Science or Practice Obtain Most Prominence on Discussions on Horticultural Subjects." Science, A. Robson, 18, Market Street; Practice, J. Henderson, Wellwood. February 19th, "Rose Propagation;" A. Innes, Ruthrieston. "The Construction of Fruit and Kitchen Gardens;" J. Forrest, Haddo House. Meetings at 8 P.M.—March 19th, "The Origin and History of a Few of the More Interesting Cultivated Plants;" Prof. Trail, Aberdeen University. April 16th, "Formation of Hardy Fruit Tree Borders and Management of Trees;" P. W. Fairgrave, F.B.S., Dunkeld Gardens. May 21st, "The Action of Light, and the Colour of Flowers;" J. Taylor, Clashfarquhar. "Peas;" R. Farquhar, Fyvie. June 18th, "An Hour among the Lichen;" G. Murray, 115, Causewayend. The Secretary is Mr. William Reid, 8, Hadden Street, Aberdeen.

JUDGING GRAPES.

Now that this most important subject is being well discussed in the columns of the Journal, I trust that all who are interested will lend their aid in trying to solve this most difficult problem. Much good may be expected from having this subject thus freely ventilated through the medium of the press. Still, gardeners should not neglect to use their influence in having the subject discussed in the horticultural societies to which they belong. I think the subject could not have cropped up at a more convenient season, as there is still enough time to have the matter fairly discussed ere the majority of schedules and prize lists are prepared for the ensuing year. It only requires a few energetic and influential individuals to take the matter up in earnest, and endeavour to induce the

leading horticultural societies to adopt some method which would bring both exhibitors and judges to a better understanding.

For instance, if a committee were formed composed of men well known for their experience and success as Grape-growers to gather evidence and carefully consider the respective merits of all the varieties of Grapes generally grown in our gardens, to decide the maximum number of points each variety ought to receive, and to draw out rules for the guidance of judges and exhibitors, such rules to partake of a kind of national character and free to any society which might choose to adopt them, the society adopting such standard rules would, by printing them in their prize lists, give intending exhibitors an idea of the lines upon which their fruit was to be judged. Besides, it would to a great extent prevent judges displaying their individual tastes and fancies, which are often as wide and diversified as the localities to which they may belong.

On page 292 of the Journal of October 1st, under this heading, "A Kitchen Gardener," while comparing Alicante to Madresfield Court, indulges in some rather hard remarks and a prophetic announcement regarding the latter variety, which must raise the ire of every lover of this noble Grape. I could not help thinking, while reading the remarks referred to, that if "A Kitchen Gardener" is as ungenerous in his cultural treatment of this variety as his style of writing about it is, I do not wonder at it both splitting, cracking, and failing to set with him. Some time ago I read in the pages of the Journal of an exhibitor who had for four or five years in succession taken first prize with this variety for flavour (black) against all comers, and that, too, at the largest Grape shows in the country, where hundreds of bunches are shown annually. So much for its "standard quality." As for its appearance, I have always been led to consider Madresfield Court has the handsomest bunch of any Grape with which I am acquainted. At the September show of the Royal Caledonian Horticultural Society a magnificent example of this Grape was shown by, I think, Mr. Brown of Abercainey, in a class for any other black, which was considered by many as the finest bunch in the show—no mean honour considering that over 400 bunches were staged. Judging from its appearance it would weigh about 6 lbs., was well shouldered and beautifully tapered, compactly built, with large berries, no evidence of any having been removed through splitting, perfectly black to the footstalk, and with a bloom as dense as any Alicante.

Again, I know a large establishment where Grapes are exceptionally well done, where this variety is as much esteemed for general use as Black Hamburg, being found as sure a cropper, as free a setter, more handsome in bunch, keeps as long, scarcely ever splits, and is found to bring to maturity a heavier crop than the Hamburg. It has peculiarities, I admit. But what first-class Grape of recent introduction has not faults? Duke of Buccleuch, Golden Queen, Golden Champion, Muscat Hamburg, Mrs. Pince, Madresfield Court, and a few others, comparatively new Grapes, have each their peculiarities, and more difficult to manage than either Alicante or Black Hamburg; but are they to be discarded and denounced as worthless, as many writers are trying to do, upon this ground alone? I daresay that during the last twenty years more matter has been written in connection with Grapes than all other home-grown fruits together. And what is to be the result of it all? Is no greater success to be expected from us than was achieved by our forefathers fifty years ago, who, with thin old-fashioned pits and frames, could grow Black Hamburgs, and such varieties, as good as we can do now? or the amateur of to-day, who, with his little greenhouse, would put many of us to shame in growing these common varieties?—D. BUCHANAN.

I AM pleased to think of the regard Mr. W. Jenkins (page 341) has had for my writings, and I should feel still more exalted if he would give me full credit for what I have written on this subject. He says I "even dispute the superiority of Madresfield Court over Alicante, and this simply on the ground of the popularity of the latter." Now, let me ask him if this was the only ground I claimed for the superiority of the Alicante? "S," who deals uncommonly fairly with his opponents, remarks at page 320, "A Kitchen Gardener" defends Alicante vigorously, and ably states his reasons for doing so. I also gave my objections to Madresfield Court, and if Mr. W. Jenkins can see nothing more in my notes than the brief distinction of "popularity," I can only say he is making poor use of his Journal. It is new to me to know that Madresfield Court has become more popular this last year or so. I have seen it better shown in Mr. Meredith's time than I have ever seen it since. "The grand bunch" shown at Dundee and "again at Edinburgh" does not speak highly for its abundance.

Referring to your report of the Edinburgh Show (page 248), I observe in the collection of twelve sorts Mr. Hammond (first) exhibited "grand Alicante," Mr. McKelvie (second), "Alicante, fine." In eight varieties, Mr. Hammond (first), "Alicante;" Mr. Jenkins, Durham (second), "Alicante, fine." In four sorts, Mr. Boyd (first), "fine Alicante;" Mr. Hammond (second), "Alicante, fine." "Messrs. Hammond and Boyd took prizes for Alicante, both with grand examples." Here we have Alicante figuring in all the prize collections, but not a word as to Madresfield Court or "the bunch" referred to by Mr. Jenkins. The same thing is occurring at all shows, no matter where they are held or who is judging, and so long as imperfectly finished Madresfield Courts are shown against those grand Alicantes all the writing in the world would never bring prizes to the former at the hands of impartial judges.

I see Mr. Iggulden has got as far as Shrewsbury in his crusade against this blind and foolish judging, but if I might be allowed to offer my candid opinion, I would say he is getting beyond his depth and including that which lies quite outside his experience. Unless it be Mr. Iggulden

no one will agree with Mr. Jenkins that the Black Hamburg cannot compete with Madresfield Court as a summer Grape.—A KITCHEN GARDENER.

THIS discussion seems in danger of ending, as others before it have done, in personalities, which are no aids to the decision of a question, and which only tend to lower the tone and weaken the effect for good which free expression of opinion and experience otherwise would have. I hope, however, that the little symptoms of personalities which have already displayed themselves may be nipped in the bud by the good sense of the controversialists, and even if that does not promise to be the case, that the editorial curb will be applied in time. My only aim and object in taking part in the discussion was the advancement of what would benefit Grape-showing and judging, totally apart from any personal desire to either appear as a "clever" arguer, or as evading important questions when put to me, as Mr. Iggulden seems disposed to think.

Whatever comes of the present discussion, I hope it will be clearly understood by Mr. Iggulden and those who side with him, that I have no desire to champion the Alicante against the Madresfield Court in a blind or bigoted way. When I said that, "other points being superior," Alicante should get the award at an autumn show in a competition, for any black Grape, even when brought face to face with Madresfield Court, which at that time would be superior—much superior, I admit—in regard to eating qualities, I simply said what I honestly think.

As long as prizes are offered in the way they are, "in season" and "out of season" distinctions will always bring about controversy. Judges must be allowed discretion in the matter, and I believe that the cases where gross injustice is done, as some would have us believe, are very rare indeed. Let there be, if it can be managed, entirely distinct classes for summer and winter Grapes at our shows. Let Alicante, Lady Downe's, Gros Colman, and other late kinds never be brought into competition with Madresfield Court, &c., and then a difficulty would be swept away. Prizes may be offered for late Grapes at autumn shows—as there will always be some growers who think they may be shown then—but keep them distinct and do away with "any other black class" if it is to be the cause of controversy.

In collections of fruit shown at our autumn shows, something the same would need to be done in regard to the varieties of Grapes shown in them. We see often a first-prize collection which has all or nearly all its Grapes composed of late varieties, which according to Mr. Iggulden should not be shown then. Collections of fruit must be in future only made up with those "in season" if the views of Mr. Iggulden and others are to prevail, or two classes be made, one in which the Grapes would need to be "in season" and the other in which late Grapes might find a place.

There can be no doubt that to exclude all late Grapes from early autumn shows would raise as much controversy as this question of "in season" and "out of season" has done. It remains, therefore, that the best that can be done is to make some re-arrangement in the classes to obviate this difficulty as far as possible, and also, be it remarked, that judges of experience and skill be in all cases chosen, so that there may be no occasion for after remarks and reflections. Those who would publicly denounce the judgment of men who are known to be without fear and without reproach, especially when their judgment has been made somewhat simpler by a slight re-arrangement of classes, are so very few that I venture to think they would never appear.

I do not forget that there are many Chrysanthemum shows held in England during November and December, but in Scotland such is not the case. This November there is to be an Apple Congress in Edinburgh, at which opportunities for displaying Grapes "in season" may be had, but I am not aware if there are any—or, if any, very many—prizes offered for Grapes, and this Congress is entirely exceptional. From September till March in Scotland there is as a rule no chance of showing Grapes at flower shows. Can it be wondered at, then, if there are numerous exhibits of late Grapes in September, especially when prizes are freely offered for them?

But Mr. Iggulden would have me believe that at these English Chrysanthemum shows there are plenty of opportunities, and much encouragement given for the display of Grapes "in season." Now I read in your Journal for October 15th some suggestions for the encouragement of Grape-showing at January Chrysanthemum shows, a time when late Grapes generally may be considered "in season." They certainly are not all, or nearly all, "in season" in November when the bulk of the shows are held to which Mr. Iggulden draws my attention. By "in season" of course Mr. Iggulden and others will understand the time when Grapes are at their best for the table. These suggestions for prizes for late Grapes in January are remarked on as being something novel, and therefore justify my remarks on the paucity of opportunities hitherto afforded for showing late Grapes at proper times. Even at the Chrysanthemum shows held in November and December I am disposed to doubt if there are as many inducements held out to Grape-growers to exhibit as Mr. Iggulden would wish to make out. Until there are many more opportunities afforded in November, December, January, February, and March for the proper display of late Grapes, I maintain that to discourage their exhibition at autumn shows will be considered a mistake; and this I do at the risk of being told that my arguments are "sentimental and worthless."

Mr. Iggulden seems anxious to account for the great popularity of Alicante. I think he may do so by calling to mind the fact that Alicante, while, to quote Mr. Iggulden, "fit for the table" in October—though I would rather say end of November—keeps plump and fresh till April, and thus allows one to "cut and come again" without the fear of finding

a "burst up" in the way of wholesale cracking, as is too often the case with Madresfield Court.

Certainly no one with much taste would care for Alicante in October, when so many other Grapes are to be had; but there comes a time when it may be deservedly appreciated. At the present moment we have both Duke of Buccleuch and Black Hamburg in splendid condition for the table, the former being golden coloured, with a rich lusciousness which cannot be excelled, if even attained, by any other Grape. As long as these last no one with any taste would think of taking the late Grapes in preference; but the latter have their value at the proper time, and are therefore duly prized.

It may be remarked that as a rule early-coloured late Grapes keep much better than those which are behindhand in that respect. This is the reason why they are in general started and forced along, so that they may be black in September, and not because, as some of your correspondents seem to think, they are wanted for showing in September, and for that alone. Experience has taught that early-coloured late Grapes are best. When prizes are offered in September, why should fault be found with those growers who have successfully coloured their late Grapes at that time—sure augury of their having Grapes that will keep—and who respond to the invitations of the prize schedules? No reasonable employer will ever grudge the cutting of a few bunches of late Grapes in September, when he is well served by his gardener, and knows that there is a good general crop to rely upon for the winter and spring, as there should ever be with those who exhibit.

Prohibit late Grapes entirely if you like from early autumn shows, if thereby Grape-growing will be improved. I for one would then not object. But until such provision can be made as would insure the exhibition and proper appreciation of late Grapes when "in season," I think it a pity to talk about excluding them from autumn shows because they are not "in season." Does Mr. Iggulden mean to assert that at the Chrysanthemum shows to be held in November and December there are prizes for late Grapes equal to those which every autumn show offers in all quarters of the land? I am afraid he cannot prove that sufficient inducement is held out at the present time, whatever may come to pass. However, I trust the outcome of the present discussion will be nothing but good, and that Grape culture may be stimulated and not discouraged by the different opinions expressed. I now take leave of the subject for the present.—S.

CHRYSANTHEMUM NOTES.

POPULARITY OF CHRYSANTHEMUMS.—Once more the season has rolled round, brimful of expectation. The anxious exhibitor is looking forward to the time when he hopes to recoup himself for his past year's labour and watchful care. Not in a pecuniary sense would he ever expect to be paid, but in the pleasurable anxiety in watching the unfolding of the flowers of the old favourites, and the anticipation of the characters of the newer varieties. The zeal and enthusiasm thrown into the cultivation of the Chrysanthemum in some districts can scarcely be exaggerated. We have heard of the same thing with the old school of florists, but we in the south never hear of a complaint called "the Tulip fever," or "the Auricula fever," but the Chrysanthemum fever is now very prevalent, and very contagious both amongst gardeners and amateurs when once it gets in a district.

THE SEASON—EARWIGS.—This year I anticipate will prove no exception to the rule; indeed, the increasing number of exhibitions and the extra amount of prizes will help and keep alive the interest amongst the older growers, and each year adds new recruits to the ranks of cultivators. Whether the exhibits this season will be up to the usual standard remains to be proved; it is rather too early to say, as much depends on the weather during the next fortnight, but certain is it the season has so far been most fickle. The early part of the year was favourable to a good growth, as the weather was so mild that the plants could be exposed to make them sturdy. Then the long spell of drought brought green fly, which was very prevalent in the neighbourhood, and also seemed to favour the production of an extra amount of earwigs, which throughout the autumn have been very troublesome. One noted grower in this neighbourhood has filled a pint and a half bottle with them in this way. A quantity of short pieces of bean stalks have been stuck in the rows of plants, and every morning these have been blown into a bottle which had a small quantity of salad oil put in at first; this kept working up as the bottle filled, and suffocated the insects as they were put in. There is not the least doubt but that these earwigs do much damage to the young shoots and buds in an early stage, and cause many deformed flowers, and if not well looked after now will soon damage a good bloom by eating away the base of the florets. If any loose florets appear lying about under the plants of a morning it is a sure indication that one has been to work in the night. The best plan is to search the plants every night by candlelight. It needs a quick action to catch them, as they have such a knack of slipping off the plants at the sight of a candle, and lying motionless on the ground.

EARTHWORMS — MILDEW.—Earthworms in the pots are another troublesome pest, especially where the extra precaution has not been taken to grow the plants on boards or tiles throughout the summer. These disturb the roots and cause the flowers to be thin and weak. A good nob of fresh unslacked lime put into a two-gallon watering can and left to settle will make sufficient lime water for a good number of plants, which is the best thing to use to kill the worms in the pots. Mildew will appear more especially on high-fed plants. The best remedy is sulphur, which should be dusted over at the first sign of it. Some varieties seem more susceptible to this than others. Val d'Andorre of the Japanese, and Triomphe du Nord, and also Dick Turpin amongst the Pompons, are the only varieties that have given me any trouble this season.

NEW VARIETIES.—Of the new varieties it is yet too early to speak, but I shall be much mistaken if there are not some good additions as to colour and size in the Japanese class. Madame de Sevin is a very promising, and I think will be a good addition. Trizon is a good colour, but I am afraid too small for exhibition. Cullingfordi is unfolding well with me, and I shall be disappointed if it does not come large enough to be included in the Japanese section, it is such a grand crimson colour. Then John Laing promises well for a good deep flower and a good colour, but like Mons. Mousillac, rather short in the petal. My favourite amongst the comparatively new varieties is Mons. Henri Jacotot, and I shall be surprised indeed if after this season it does not become a general favourite. It is a grand colour, crimson, of good size, and very certain. Of the others more anon as the season gets on.—C. ORCHARD, *Coombe Warren*.

CHRYSANTHEMUMS AND THE FROST.—Like "J. L. B." I, too, had been waiting to read accounts of the damage done to Chrysanthemum by the frost of September 27th before I recorded its effects, which I regret to say are serious, for the majority of the plants are more or less injured according to the stage the bud was in. Not expecting the temperature to fall to 24°, as it stood at 35° at eleven o'clock on Saturday night, I had only housed the earliest plants showing colour, when on Sunday morning a sight met my eyes I shall never forget. To have seen in September Chrysanthemums blackened by one night's frost, especially in the case of the Pompons, also Meg Merrilees and Peter the Great (Japanese). Scarcely a flower of the Pompons will open, they look as though they had been near a fire and got scorched. The large varieties are now showing the effects, since they have been housed a fortnight. Many of the crown buds are quite decayed; others are attempting to force out a few outside petals, but the centres are gone; some had the footstalks injured and, becoming soft, the buds hung down. In the case of Princess Teck and Meg Merrilees the buds were killed, so that I have cut the plants down together with many others.

They were all arranged in rows 3 feet apart on a piece of ground covered thickly with ashes in a situation open to the south, east, and partly to the north-east, sheltered on other sides by the plant houses, it being the only vacant space available here for the purpose. The district is low and damp. Dahlias, Pelargoniums, and all other tender plants shared the same fate.—A. A., *Mitcham*.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S ANNUAL MEETING.—The annual general meeting of this Society was held at the Old Four Swans Inn, Bishopsgate Street, on Monday, the 19th inst., when there were over thirty members present, Mr. E. Sanderson presiding. The minutes of the last general meeting were read by the Hon. Secretary, Mr. Wm. Holmes, the Society then proceeding to elect new subscribers and transact other business. It was stated that there are now over 290 members, and that sixteen provincial societies have become affiliated with the National, medals having been supplied to those who desired them. The Secretary read a letter from one correspondent in which it was proposed that the National Society should form a list of competent judges for Chrysanthemum shows and recommend them in rotation to such societies as required their services. No action was, however, taken in the matter. A sub-committee was then appointed to frame rules for the guidance of the Floral Committee. Mr. Wm. Holmes referred to the proposal that classes for late Grapes should be provided at the Show of late Chrysanthemums in January, and stated that the Society's funds would not admit of prizes being offered for the purpose named, but that he would be pleased to co-operate with all who are interested in the matter if a special fund could be raised. The meeting concluded with the usual votes of thanks to Mr. E. Sanderson, Mr. Wm. Holmes, and Mr. Ballantine.

CHRYSANTHEMUM SOCIETIES.—The Lambeth Amateur Society

will hold their Show in the Hawkstone Hall, Westminster Road, November 3rd and 4th, and a satisfactory display is expected, though the date is somewhat early. Yeovil Show takes place on November 17th; Havant, November 5th and 6th; Walton, November 12th; and Wimbledon, November 17th. The schedules including the usual prizes.

LONDON EXHIBITIONS.—The Exhibitions at the Inner Temple and Finsbury Park are now open to the public, but are not yet at their best. A week of fine weather will, however, make much difference.

CUTTING DOWN APPLE AND PEAR TREES.

It is known, and the fact is sometimes acted upon, that by cutting down old Grape Vines young ones are produced from the old stumps, which yield much better crops than could be obtained previous to this surgical treatment. It does not seem to be so generally known that the same operation may be advantageously carried out on old worn-out Pear and Apple trees to renew the vigour and bearing qualities of the tree. I have seen old trees with gnarled and knotted stumps, which for years has been fruitless, or occasionally so far fertile as to bear a few fruits of the poorest quality, after having been cut over send up strong, healthy, and fruitful growths, which bore large crops of the best quality. One of the Apples most subject to canker in the garden here is Cellini, yet I have cut a tree of this in the most robust health, which previous to this treatment was, to all intents and purposes, entirely worthless. We have a Pear tree which was apparently in robust health, yet year after year failed to set a fruit; by the simple process of cutting down a portion of the branches and the fresh young growth resulting therefrom, has for several years back regularly borne crops. In this case it was not necessary to cut every branch, and we find that by an occasional judicious cutting out of the main worn-out branches in bush Apple trees, that the few strong young growths thus encouraged impart a fresh vigour and fruitfulness to the whole tree. We have a curious commentary supplied just now, by a tree treated in the above manner, of the failure of grafting another variety on to a worn-out tree to do more than secure that object for a time. The scion is of the variety Hoary Morning, which having become rather worn-out had some of the branches cut well down to the base of the stem. Instead, however, of the same sort coming away, the result has been strong shoots of a later dessert variety of very heavy cropping proclivities. Of course there can be no objection to grafting good varieties on to poor ones, but I have no doubt that in this case, as so very often happens, the closely pruned branches had become comparatively barren, therefore condemned, and another sort forthwith grafted on to it. If the branches had been cut down and not grafted the tree would have been carrying large crops much quicker than it was possible for it to do when grafted.

Root-pruning has become a common practice as a means of restoring old trees to fruitfulness. Now, while it would be wrong to condemn this practice as unnecessary in all cases, at the same time no doubt much unnecessary labour is expended in carrying out this work in a scientific manner, keeping the greater part of the outdoor staff employed during the best portion of the winter months with results by no means commensurate to the outlay, when a judicious thinning-out of some of the main growth and the encouragement of young ones to replace, would have secured the end in view much more effectually and cheaply.

As there is no better time than the present to operate in the direction, and for the reason indicated, those who have trees either of Apples or Pears in an unsatisfactory condition would do worse than experiment a little in cutting down. I am perfectly certain from my own experience, and from what I have seen elsewhere, that there exists no cheaper, quicker, or more effective means of securing fruitful healthy trees than this one. If a garden is well drained and produces good vegetables there is no reason why it should not also produce good hardy fruits, provided plenty of vigour is kept in the trees by a systematic production of young growths following the removal of that which is exhausted and therefore barren.—B.

NYMPHÆA DAUBENIANA.

It would be impossible to say too much in praise of this neat and beautiful Water Lily. Among all the Nymphæas here none have been admired more this season than this one. Often we have had seven fully expanded blooms on a plant, the largest measuring from 7 to 8 inches. It is a most persistent and free-blooming variety, being in flower from May to October. The colour of the petals is a sort of creamy white suffused with violet, the centre is orange, and the stamens also are orange tipped with violet. It has a most deliciously fragrant perfume, which it is quite impossible to describe. It is the sweetest of all the Nymphæas. It may be easily cultivated in an ordinary stove provided it gets a moderate amount of light, and the temperature of the water is maintained at 70° or 75°. A tub from 2 to 3 feet wide and 12 or 15 inches deep is quite sufficient for its requirements. Place about 2 inches of crocks on the bottom of the tub, and on these about 8 inches of good loam mixed with a little decayed well-seasoned cow manure. In planting care should be taken not to bury the crown of the plant too deep. Warm fresh water should be added to the tub three or four times a week. It

must be kept clear of insects by syringing, and of sediment and decayed leaves. This species does not produce suckers freely, but is easily propagated in spring either from the leaves or division of the old root.—O. THOMAS, *Chatsworth*.

[We were surprised to find that the cut flowers kept fresh and frag-

out of doors, yet it requires to be flowered in a greenhouse to have it at its best, the flowers opening so much better and of a purer white under glass than in the open. Indeed, plants used for room-decoration in positions away from direct light have produced the best flowers I have seen. For the above purpose no plant is better adapted, standing as it does the rough-and-ready usage of house-work better than any other

FIG. 56.—*NYMPHEA DAUBENIANA*.

rant in water for ten days, opening and closing at intervals, and diffusing a perfume somewhat like Violets, but richer and more powerful.]

NICOTIANA AFFINIS.

THIS is one of the best decorative plants we have, and, judging from what I have seen, is not nearly so well known as its good qualities entitle it to be. My experience with it is that, although it will grow and flower

flowering plant I have tried. It also adapts itself in the most convenient manner to any size that may be wished to grow it. I have had little plants in 3-inch pots which have come in as useful as larger plants with twenty times the amount of bloom. The best way to use the plants is to dot them amongst those which are much dwarfer, a few specimens quite altering the appearance of a group of plants, and that for the better.

It is so easy of cultivation that a few lines will enable me to note the salient points thereof. I sow the seeds in March, in heat. The seedlings

are pricked off when large enough into boxes, and in due time placed singly into 3 or 4-inch pots and grown on in cold frames. Good plants may be produced by shifting again into 7-inch pots; and extra large ones by another shift into those 10 or 11 inches across. The soil used for them is a good loam enriched with a third of cowdung and a sprinkling of bonemeal thrown. Plenty of water must be supplied in all stages and as required. Manure must be given either in the water or on the surface to be watered in. The plants are best grown on out of doors until the flowers begin to open, when they will be greatly improved by being placed under glass to expand. It may be noted that the flowers, though scentless in the daytime, are sweetly scented in the evening.—B.

SCRAPS ABOUT FRUIT.

Now that we have such an excellent hardy fruit season it would prove highly interesting to fruit-growers in all parts of the kingdom if the Editor would kindly devote a small portion of its columns to publishing short notes or scraps on hardy fruit, similarly to the method adopted in these pages a year or two ago. Such would enable growers to have an interchange of opinions on the merits of the different varieties of fruit, which could not fail to be of great service, independently of the advantages of the Pear Congress, to the numerous readers of the Journal. I give two for a start, and hope the example may be followed by others.

GANSEL'S BERGAMOT PEAR.—A capital variety for growing on the cordon system. With us it is a free grower and a good cropper, and yields large handsome and highly coloured fruit, with white buttery flesh, and a very juicy, sugary, and delicious rich flavour. Grown as a pyramid it is very inferior as regards flavour except in the more southern districts. It requires to be grown against a south or west wall to bring out its beautiful colour and delicious Bergamot flavour.

BEURRE D'AMANLIS.—Another valuable September Pear suitable for cordon training. Grown on a wall, same aspect as the preceding variety, a cordon 8 feet long bore eighteen large handsome fruits, which were of a deliciously melting, buttery, and rich juicy flavour. This variety is not so well adapted, in our experience, for pyramidal training, being of a too straggling habit of growth.—T. W. S.

THE GLADIOLI AT SOUTH KENSINGTON.

I DO not think that the remarkable collection of Gladioli shown by Mr. Campbell of Gourock, N.B., should be passed over with the short notice given in last week's Journal, for I have no hesitation in saying that it was the most remarkable collection ever exhibited (in the south of England, at least) in the middle of October, and reflected great credit on the grower, both for the character of the blooms and for his enterprise in bringing them up such a distance and setting them up in such grand condition. As I have seen almost every exhibition of these grand flowers and am the oldest amateur grower of them in the kingdom, I feel that I may speak with confidence about them. The Royal Horticultural Society gave them the highest award it could do, but it ill requited Mr. Campbell for the expense and trouble he had been put to in bringing them up to London.

When I said they were remarkable for the middle of October, I do not mean to say that there was any need of excusing them in any way on account of the lateness of the time when they were exhibited. On the contrary, on comparing them in my mind with what Mr. Campbell exhibited at the Crystal Palace five weeks or more since, I believe that they were fully equal to those then exhibited. When you get spikes with ten or twelve expanded blooms bright and clean in colour, I do not think that any excuse is needed for them, and that was the case with those exhibited on Tuesday last. The same feature, too, was as noticeable now as then, that many of the older varieties which many had thought had been entirely superseded were exhibited in such form that one will have to "hark back" to them again.

Amongst the best of the varieties staged were the following:—Adolphe Brongniart, rose tinted orange, an old flower, but still one of the best; Africaine (1878), slaty brown on scarlet ground with white centre; Amalthee, pure white tinted violet, a long spike well arranged, and, although out some years, still valuable; Anna, cherry, tinted orange, carmine stripe on white ground; Archduchess Marie Christine (1879), white tinted lilac, flamed rosy carmine, a fine large flower; Baroness Burdett Coutts (1879), delicate lilac tinted rose, flamed rosy purple, a large and striking flower; Belladonna, white tinted clear lilac, lower petals striped bright carmine; Caméleon (1880), steely lilac, flamed orange, white lines; Coïenne (1880), rosy carmine, shaded cherry, creamy white blotch; Crepuscule (1883), a long spike, but somewhat too narrow; Dalia (1880), one of the best grown, bright rose, streaked and flamed carmine, large pure white blotch. There were several spikes of this with ten and eleven expanded blooms. Delicatissimus, an old flower, but pretty, white flamed and edged carmine; De Mirbel, fine rose, tinted lilac violet; Dumont D'Urville (1879), very long spike, bright cherry; Flamboyant (1881) fine spike of bright scarlet flowers, a very remarkable variety; Hesperide (1878), white ground, flamed rosy salmon; Leandre, lilac, slightly shaded carmine, white lines, large white blotch; L'Unique Violet, dark lilac, tinted violet, flamed dark violet; Marquis of Lothian, flowers fresh, rosy lilac, good form and substance, a northern flower raised in 1875, very robust; Meyerbeer, brilliant red, flamed vermilion, an old and fine flower; Murillo, rosy cerise, white lines, white throat, good; Psyche, clear light rose, flamed light carmine; Roseus perfectus, rose tinted violet; Samuel Jennings (Kelway, 1880), scarlet, with white

blotches on lower divisions; Tour du Monde, dark cherry red, white blotch, edged lilac.

It may be asked, How could such flowers be exhibited in such condition after the severe and stormy weather we have lately experienced? It is astonishing how much of this rough weather the Gladiolus will stand without injury if they are properly staked, but in this instance these flowers had been covered by wooden cases made expressly for them, and by means of which they are protected from all weathers. I do not, of course, know what is Mr. Campbell's mode of culture, but whatever it may be he has safely established himself as one of the foremost cultivators of this grand but capricious flower.

I cannot forbear saying what a splendid flower it is for cutting, and what a prolonged season of bloom one can have. I only planted some 400 corms, and yet from the middle of August I have had a succession of fine spikes, and I, this day, Oct. 17th, cut, I suppose, the last of them, although I see a few others which may yet flower; nor were these I cut to-day poor things, but really good spikes with a number of finely expanded flowers of good substance and bright colour.—D., Deal.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE CABBAGE.

LIKE that useful vegetable, the Potato, the demand for which is little affected by the diatribes of some modern philosophers who regard it as comparatively innutritious, the Cabbage, in one or other of its varieties, is to be found upon dinner tables all the year round. The circumstances of the growth of most of these render them very liable to the insidious attacks of insects, and there is not a month from January to December during which some species is not getting its subsistence off a Brassica that is under garden cultivation. A considerable proportion, however, of the Cabbage-loving insects are easily kept under by a moderate amount of care, and others less readily detected are seldom numerous enough to cause serious damage. Needless alarm has occasionally been excited amongst the growers of Cabbages and kindred vegetables by reports concerning destructive insects, circulated in ignorance of the fact that generally each species keeps to its particular food. Thus in 1782, when the caterpillars of the brown tail moth swarmed in several counties, an apprehension arose that they would lay the kitchen gardens bare, because people did not know they fed only on fruit trees. Also it has happened that when a few specimens of the great green grasshopper have wandered from field or hedgerow in amongst the Cabbages, a gardener has regarded them with disgust, on the supposition they were the pioneers of a hungry company of locusts.

In referring to the insects that commonly occur upon Cauliflowers, we have given an account of the caterpillars of the great yellow underwing (*Tryphæna pronuba*) and of the abundant Cabbage moth (*Mamestra brassicæ*), concerning which it will not therefore be needful to say more here than that there are few seasons when these insects are not observable in our gardens, though sometimes their numbers may be comparatively small. Also, we have named the small white butterfly (*Pieris rapæ*) as an insect which in its larval state presses to the heart both of Cauliflowers and Cabbages, yet from its habits and size is a less serious enemy to our plants than is its relative, the large white (*P. brassicæ*), an object pretty enough while it is on the wing in the summer sunshine, but too pernicious amongst vegetables to get much encouragement from us. Yet personally we must confess to a bit of sentimentalism which makes us loth to kill a butterfly, and there are other ways of keeping this species under even more efficacious. Like the small species, it is flying about as soon as winter has departed eager to deposit eggs, and caterpillars of the autumn brood may be taken until the end of October in the kitchen garden or on Cruciferous plants in the flower beds. It is scarcely necessary to describe so abundant a butterfly as this, but the fact should be noted for the benefit of those who may incline to destroy the perfect insect, that the females have several black spots scattered over the wings, which are lacking in their male companions. Since the eggs are deposited by the parent flies in clusters of three or four to a dozen, they may be found upon the leaves of Cabbages (and also upon Mustard and Turnip) during May, and by picking them off a check is given to the increase of the species at an important period. These eggs are yellow and ribbed, standing up on the leaves like tiny ninepins; the first business of the juvenile caterpillar is to devour its eggshell. If left undisturbed the period of caterpillar growth occupies about a month, on any alarm they drop hastily from the food plant, though, as Newman pointed out, they return almost exactly to the spot they quitted after the danger appears to be over. That velvety aspect displayed by several caterpillars of this genus is not discernible in *P. brassicæ*, which is bluish green above, paler below, and lined with yellow; all over the body are warts, each topped by a hair.

Having had these caterpillars repeatedly under observation, I was at one time inclined to think that there were three broods each year, not two only, as is the general statement of British entomologists. For it is certain that in most counties there are but very short intervals during the season when we fail to perceive them upon some Brassica

in field or garden. I conclude now that there is a succession belonging to both the spring and summer broods, their appearance being gradual, so that while young caterpillars are feeding, hatched from eggs laid by butterflies early out of the chrysalis, more butterflies are emerging from that stage of life. It is probable some of the chrysalids are destroyed by birds, because the insect thrives most where there are plenty of places in which it can find concealment during the period of torpidity amongst palings, walls, and the like. Hide as it may, however, a tiny parasite (*Pteromalus Brassicæ*) finds the chrysalis when yet soft, and depositing a hundred or more eggs thereupon renders its appearance as a butterfly impossible. Equally valuable to us are the services rendered by another parasitic fly called *Microgaster glomeratus*. This attacks the caterpillar before pupation, and numbers of them may be seen upon walls, shrivelling up in a vain attempt to transform, while soon after their bodies are covered with the yellow silky cocoons spun by the fly maggots. Some persons who really ought to know better take these to be the eggs of the caterpillar, and so they crush them, thereby killing the germs of a friendly insect, for the influence of these flies in keeping the species under is considerable.

All chrysalids seen should of course be removed. Many may be found from autumn to spring, and again in June those producing the second or summer brood are about. Proceedings against the caterpillars may be taken in various ways. Some gardeners have employed, it seems, children to pick them off, paying so much a pint for the caterpillar carcasses; this cannot well be done except in a limited area. Dressings that would destroy caterpillars on many plants are not, for obvious reasons, suitable of application to Cabbages; watering them with brine, lime water, or weak soapsuds might be safely tried, and the effect of simply drenching the plants with water is good, the colder it is the better, since it produces a very injurious effect upon the caterpillars, they are unable to eat, and die off speedily.

Allied to the Cabbage moth and placed in the same genus is the species called the Dot (*Mamestra Persicaria*). The moth is of a dark or chestnut brown, with a conspicuous spot of white upon the fore wings, hence the English name. The caterpillar is rather given to wander from plant to plant, feeding on various species in the flower or kitchen garden, and it has been taken upon Cabbages during July and August. When adult it is $1\frac{1}{2}$ inch in length, greenish or brown, the head being small and glossy; on the sides are a series of markings resembling the letter V, with the point directed towards the tail. It is one of those caterpillars that are frequently devoured by birds. A rarer species of this group, *M. albicollis*, is occasionally found as caterpillar on Lettuces and Cabbages; it favours the west of England.

Although *Hadina oleracea* has, beside another familiar name, received that of the pot herb moth, it is commonly reared upon such wild plants as Nettles and Docks, but still sometimes makes an irruption upon our gardens, where the caterpillar hides at or just above the roots of several vegetables of low growth, including the Cabbage. It is much lighter in colour than that of the Cabbage moth, usually green, marked with black and white, feeding in August and September. As a remedy, diluted gas liquor may be poured round the stems of plants, or soot, lime or ashes wetted with oil of tar sprinkled upon the soil. We must at least mention the caterpillar of the silver Y moth (*Plusia Gamma*) as an insect that may be taken feeding upon Cabbages. It is what is called a half-looper, having only twelve feet, grey in colour with lines of pale yellow, but seldom troublesome in Britain. On the Continent it positively swarms in some kitchen gardens, devouring every plant that is accessible.—
ENTOMOLOGIST.

NOTES UPON DAFFODILS AND NARCISSI.

It is doubtful whether any flowers are more popular than these. At the present time the general demand for them is enormous, and has been for several seasons past; but an immense impetus was given to a previously large trade by the Daffodil Conference held in London in April, 1884, when a magnificent display was made. Previous to this they were admired by a large circle of enthusiasts, but the number has greatly increased. Many amateurs, however, are not satisfied with some of the bargains they purchase; cheap offers of Daffodils are taken advantage of, but when the flowering season comes, the wild *N. Pseudo-Narcissus*, collected, may be, direct from some meadow or wood, is found to be the one in the garden, and a disappointment is experienced. The price of many of the best varieties is much against their cultivation. We may hope they will be within reach of most of the flower-loving public at some time; meanwhile, much greater discrimination might be exercised in purchasing the cheaper but really beautiful kinds in limited quantities for garden decoration, rather than spending even small amounts upon one common variety. No wonder

Daffodils are so popular when we consider their hardy constitution, time of flowering, and their value as garden ornaments and for floral decoration. If a good selection is made a long feast of their beautiful forms may be enjoyed for many weeks of the spring season, beginning with the little *nanus*—often called the "Fairy Daffodil" in Ireland—and *obvallaris*, and ending with the later varieties of *N. poeticus*. Their value in a cut condition can scarcely be over-estimated.

The demand for some varieties is enormous. For instance, I knew one grower who sent not less than 500 dozens of *N. poeticus ornatus* to one florist in Scotland the day before Good Friday last, and every one were sold; and turning to some correspondence I have upon the subject I notice that one grower in the Scilly Isles sent off, mainly to London market, not less than 2000 dozens of the same variety during Easter week, while as many as 8000 dozen blooms, of only a few kinds, were despatched in one week by the same grower, and all realised a remunerative price, so much so that their culture is being largely extended, about five acres of land being now occupied with them. One word of advice is useful on this point. They should be cut in an advanced bud state, and expanded in water, if in a warm room or greenhouse so much the better; the flowers will be much larger, cleaner, and last longer than if allowed to remain upon the plants until quite expanded. This is an immense advantage, especially when required for sending a long distance; the forward buds can be cut, stood in water for a time, and then pack for travelling.

A few words as to the best method of growing Daffodils may be useful now, as this is the season for planting. As little delay as possible should be allowed now, as it is quite time the bulbs were under the surface. They can be arranged in clumps, lines, or separate beds. I much like to see them in separate beds even if small, but as that method occupies a large amount of space when a large collection is dealt with, it cannot be generally commended. I have many thousands, all of which are arranged in lines in beds about 4 feet wide. Clumps are very convenient for borders, but it is necessary to label carefully and to mind the tallies are not lost. The *Polyanthus* varieties do best in a warm sunny position as well as the silver Trumpet varieties, such as *moschatus*. All require a well-drained soil, well enriched with rotten manure; that from a stable I have found most satisfactory. A deep stirring of the soil is needful, and the manure should be placed beneath the bulbs, a little soil being put between so that they are not in direct contact with it. This means a little extra trouble, but the result is more than commensurate with the labour incurred. Big bold Daffodils will be the reward, as well as unusual bulb-development, which in the case of choice forms means much. Under this treatment my stock of *Empress* doubled itself in one season, while 300 bulbs of *poeticus ornatus*, planted last autumn, produced when lifted in July last 930 bulbs, none very small, and many much larger than the originals.

Usually we call all the *Narcissi* Daffodils, but this is not quite right. I think the term should be applied to the Trumpet series, of which our wild *N. Pseudo-Narcissus* is the type, while all the rest should be called *Narcissi*. Mr. Baker of Kew has made a very simple arrangement of the genus into three groups—viz., 1, *Magni-coronatae*, or Large Trumpet section, in which the trumpet is very large, and which at one time were classed under the generic name of *Ajax*; 2, *Medii-coronatae*, or Medium-cupped, including the peerless Daffodil of Parkinson (*N. incomparabilis*) and some others; and 3, *Parvi-coronatae*, or Small-cupped, the true *Narcissi*, of which the "Poet's Narcisse" is the type. There are many hybrids in each section, between individual members of the same and between those of different sections, so that you get now a well graduated line from the smallest to the largest cupped section. Many are natural hybrids, and a very large number are the result of artificial cross-breeding, and further crossing is being actively pursued by enthusiasts at the present time. Most interesting it is, as there is not much difficulty attending it; but much patience is required, as some years elapse before a seedling produces its first blossom—five or six on the average. I hope to see three most interesting bulbs flower next season, as I believe them to be a successful cross between *N. Horsfieldi* and *N. triandrus*, two such variable kinds, that something odd may be expected.

It is extremely difficult to make a very rigid selection of these charming flowers to meet a general want. Everybody who wishes to grow them should see a good collection in bloom and make their own choice. I grow about 120 varieties, and made numerous notes at the time of flowering upon the best, with the idea of communicating them to the Journal earlier, but it is likely they will be interesting now that the bulb lists are being

examined. Taking the groups in the order previously named, I will make a few remarks upon the best varieties.—J. T. R.

(To be continued.)

THE NATIONAL PEAR CONFERENCE AT CHISWICK.

OCTOBER 21ST TO NOVEMBER 4TH.

THE Royal Horticultural Society opened yesterday (Wednesday) at their Chiswick Garden an Exhibition of Pears, which in extent and importance is second only to the extraordinary Apple Congress held two years ago in the same Garden. The season selected for the Apples was one that proved exceptionally favourable to that crop, and the present season was chosen for a Pear Show from similar reasons—namely, the general quality and abundant supplies. The result, as seen in the display now provided at Chiswick, is all that the promoters of the scheme could have wished, and more than was expected by many who could see the greater difficulties in the way of obtaining an Exhibition of Pears. Happily these have been surmounted. Gardeners and nurserymen in all parts of Great Britain have responded freely to the invitations, and, without the pecuniary temptations usually deemed indispensable, have provided an Exhibition of which all concerned have ample reason to be proud. These Congresses and Conferences possess that very agreeable feature, the combination of horticulturalists for a common benefit without the striving and struggling for money prizes that have in some cases almost rendered exhibiting a matter of business, and the numerous visitors who inspect this great Pear Show will not find their interest decreased by bearing in mind that it has been provided without offering a prize of any kind.

In round numbers about 6000 dishes of Pears are entered, occupying the whole of the large vinery and a spacious tent. The chief part of the display is of course in the vinery, where there are two wide tables extending the whole length of the house, and each bearing six rows of dishes. The side stages are also fully occupied, and the whole produces a wonderful display such has certainly never been obtained before at one time. In general effect Pears are less beautiful than Apples; there are few of the rich and varied colours which render the latter so charming, the brilliant red and crimson hues are wanting, but in their place we have some sober autumn tints, with a quieter beauty. Gold, with several shades of yellow and many browns, are the most noticeable, then there are innumerable shades of green, relieved in a few instances by a flush of warm crimson, all seeming suggestive of the falling leaves. In form there is more diversity amongst Pears, for we see gradations from globular fruits like Apples to long slender and elegant-looking fruits that would scarcely be thought to belong to the same family. In size also we find similar variations from pigmy Hensles and Sultans $\frac{1}{2}$ inch in diameter to giants of the Belle Angevine type 7 inches high and 15 inches in circumference.

The practical horticulturist will, however, find much more than this to instruct him, for accompanying each variety is a card telling many important particulars besides the name, the stock upon which the variety is mentioned, the average fertility, and other remarks, of which the value will be readily understood. Thus the Pears most suited for particular districts can be seen at a glance, and gardeners are fully aware how much success is dependant upon a selection of varieties adapted for the locality. It is surprising how altered a variety becomes in unfavourable circumstances, and in the Show in question there are innumerable instances of this kind that well deserve attention. Upon this, indeed, and the correct naming of the varieties submitted to the Committee, the real practical value of the Conference depends. By chronicling all the facts so collected, and correcting the nomenclature, they will be doing the whole fruit-growing community an inestimable service.

Up to midday on Wednesday Mr. A. F. Barron and his staff of assistants were busily occupied in arranging the enormous number of exhibits, and anyone who saw the hundreds of packages and boxes arriving on Tuesday would have thought it almost impossible that order could so soon have been obtained from such a chaos. By late and early working the greater portion of the exhibits were ready for the inspection of the Committee by 1 p.m. yesterday. As, however, it was impossible for us to then obtain a full report for the present issue, we can only give a few statistics, reserving further notes until next week.

England, of course, is largely represented, contributions being entered from thirty-five counties. Wales, Scotland are also represented, but to a much smaller extent, while from Jersey, Guernsey, and France collections of considerable merit have been forwarded. Concerning the English counties several interesting facts we observed. Dividing them into eighteen southern and seventeen northern counties, the following are the respective number of dishes from each.

SOUTHERN COUNTIES.—Middlesex, 694; Kent, 538; Surrey, 521; Herts, 445; Hereford, 343; Essex, 225; Bucks, 200; Devon, 189; Wilts, 133; Sussex, 182; Hants, 103; Dorset, 110; Somerset, 30; Gloucester, 98; Berks, 84; Oxfordshire, 41; Bedfordshire, 20; and Monmouth, 30. Total, 3985 dishes.

NORTHERN COUNTIES.—Nottinghamshire, 159; Worcestershire, 140; Yorkshire, 105; Northampton, 80; Staffs, 55; Leicester, 50; Cheshire, 50; Hunts, 52; Rutland, 50; Shropshire, 25; Warwick, 12; Norfolk, 52; Suffolk, 25; Lincolnshire, 30; Lancashire, 35; Derby, 12; and Cumberland, 2. Total 970 dishes.

We thus see that from the southern portion of England there is four times as many exhibits as from the northern half, and the first seven of the counties represent a total of 2968 dishes, or about half the whole number exhibited. It may be remembered also that at the Apple Congress Kent took the lead in numbers; this time, however, Middlesex heads the list by 150 dishes, due in a great measure, no doubt, to the contributions from Chiswick Garden. The lowest number is from Cumberland, two exhibitors sending one dish each. The greatest numbers of exhibitors are from Middlesex, Surrey, and Kent, the two first with fifteen each, and the last with eleven.

There are 170 exhibitors, the following showing fifty dishes and upwards:—Royal Horticultural Society, 200; M. Leroy, Angers, France, 196; Messrs. J. Veitch & Sons, Chelsea, 150; Messrs. W. Paul & Son,

Waltham Cross, 150; Messrs. T. Rivers & Son, 150; Mr. G. Pragnell, Sherborne Castle Gardens, 110; Messrs. G. Bunyard & Co., Maidstone, 100; Mr. C. Turner, Slough, 100; Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, 103; Mr. Wm. Wildsmith, Heckfield Gardens, 90; Messrs. G. Paul & Son, Cheshunt, 80; Mr. Le Cornu, Jersey, 80; Mr. E. Cole, The Gardens, Althorp Park, Northampton, 80; Mr. W. Coleman, Eastnor Castle Gardens, Hereford, 90; F. C. Barker, Esq., Heatherdale, Woodford Green, 50; Mr. C. Davies, The Moat Park Gardens, Maidstone, 50; Messrs. F. & A. Dickson, Chester, 50; Mr. F. Jamin, Bourgl-la-Reine, Paris, 50; Mr. Denning, gardener to the Earl of Chesterfield, Holme, Lacey, 62; Messrs. C. Lee & Son, 60; Mr. J. Renwick, Melrose, 50; Mr. J. Roberts, Gunnersbury Park, 50; Mr. J. Burnett, Deepdene Gardens, 55; Mr. S. Ford, Leonardslee, Horsham, 73; Messrs. R. Smith & Co., Worcester, 60; Mr. J. C. Mundell, Moor Park, 60; Mr. Thomas, Orchard Lane Gardens, Sittingbourne, 70; Mr. C. Haycock, Barham Court Gardens, 76; Mr. J. W. Dance, Gosfield Hall, Halstead, 61; Mr. P. Middleton, Wynnstey Gardens, Ruabon, 60; Mr. E. Cole, The Gardens, Althorp Park, Northampton, 80; Messrs. J. Cheal & Son, Crawley, 60; Messrs. Harrison & Son, Leicester, 54; Mr. H. Ritchie, Eardiston Gardens, Worcester, 50; and Mr. G. Breese, Petworth, 50. From Wales 143 dishes are sent; from Scotland, 134, not including those from Mr. Dunn, of Dalkeith Palace, which had not all arrived; and there are some from Ireland.

We should advise all interested in this Conference to visit Chiswick as early as possible, for there are many of the finer Pears that are now ripe which will not keep in good condition so long as the Apples did at the previous show.

AUTUMN SHOWS.

EXHIBITORS of Chrysanthemums will soon be actively engaged in preparing for the numerous shows announced for the present season, and the following list of fixtures may be useful as a reminder. Secretaries of Societies not mentioned will oblige by forwarding their schedules.

October 21st to November 4th.—Chiswick (Pear Congress).
October 27th and 28th.—South Kensington (Chrysanthemums and Vegetables).
November 3rd and 4th.—Ealing, Southampton, and Lambeth.
" 4th and 5th.—Brixton.
" 5th and 6th.—Richmond, Havant, and Highgate.
" 10th.—Southend and Putney.
" 10th and 11th.—Brighton and Kingston.
" 11th.—Basingstoke.
" 11th and 12th.—National Chrysanthemum Society and Croydon.
" 12th and 13th.—Lindfield and Portsmouth.
" 13th and 14th.—Huddersfield.
" 14th.—Ramsbottom.
" 17th.—East Grinstead and Devizes.
" 17th and 18th.—Lincoln and Winchester.
" 18th and 19th.—Northampton, Bristol, and Birmingham.
" 19th.—Taunton, Hammersmith, and Aylesbury.
" 19th and 21st.—Hull.
" 20th and 21st.—Sheffield.

STEPHANOTIS AND GARDENIAS.

It is rather surprising that the culture of these plants should be denounced, considering that their blooms are amongst the most chaste and beautiful of any we possess, and their successful cultivation is looked upon by many as a great achievement. Exception is taken to the fragrance of the Gardenia, and Mr. Muir states, page 295, that not one person in a dozen can really enjoy it, but I maintain that the perfume of Gardenia is as much prized as that of any other flower grown.

The Stephanotis must be cast away because its flower stems are so short and it cannot be comfortably arranged with anything else. Our plan is to put it by itself (except an edging of greenery), and for this purpose shallow vases or dishes are used, which are appreciated as much as any combination of colours—certainly they are not suited to mount on the top of tall vases or glasses.

If the cultivation of Gardenias was better understood there would not be so much need of the sponge. Procure cuttings thoroughly clean, and strike them at any time in any hot close frame, and when rooted pot them or plant them out. Never allow them to become root-bound, and syringe them heavily twice a day, and they will make fine plants a yard through or more in about eighteen months, with foliage as healthy as Laurels, and each plant will give scores of good blooms. Both these plants are as easily kept clean as many other stove occupants, such as Dipladenias, Ixoras, Crotons, &c. But what are we to grow in place of them? Of course no one will say a word against the Eucharis, but they must be grown in enormous quantities in order to give cut flowers all the year round, such as can be obtained from a dozen or two well-grown Gardenias, and we have been cutting Stephanotis since March, and hope to continue so until nearly Christmas.

As to the blooms of Gardenias being almost black after travelling, the fault is with the packing, as mine used to be so at one time, but since then I have learnt a lesson, as they generally arrive as "fresh as cut" after a sixteen to twenty hours journey. If Mr. Muir had some employers, they would perhaps prefer to "throw him away" and retain their Gardenias.—W. J. IRELAND.

MR. E. JENKINS, page 324, writes of these as if they were the only pretty and good flowers in our gardens. He would observe that I only wrote against them being taken in by those who were obliged to place them with other plants, and I said nothing against their cultivation in special houses. I may, however, verify my former remarks, and assert that I have known scores of growers, both amateur and professional, who had all their indoor plants together, complain bitterly of the extraordinary increase of pests which was continually taking place after these plants were introduced. There is nothing difficult in finding substitutes for both. Bouvardias, especially candidissima, jasminoides, and Humboldtii corymbiflora are as delicate and pretty as Stephanotis in summer, and far

more useful throughout the entire winter. The *Eucharis*, which was noted before, *Pancratium* in variety, *Jasminum sambac* and others, *Daphne indica alba*, and *Tabernaemontana flore-pleno*, any one or all of which are as pure and delicate as the *Stephanotis* or *Gardenia*. Most of them are fragrant, and all are white.

I am glad to see Mr. Pearson call attention to the statement of Mr. Jenkins respecting the price of *Gardenia* blooms; 2d. each is a great deal nearer the mark than 50s. per dozen. Did ever anybody sell a *Gardenia* bloom for 4s.? I was never offered £10 to find a mealy bug in the Chilwell Nurseries, but the late Mr. Pearson has told me more than once that he would give me a sovereign if I could find one, and I never won it; but how few could say this. "C. S. R." must be possessed of a very meek and mild type of mealy bug if it is exterminated by soapsuds. I congratulate him on making such a valuable discovery.—J. MUIR.

THESE are two favourites here, and I should be very sorry to see them discarded. As to bug, we have none on the place, nor anything to speak of in the way of insects that disfigure or injure plants. When we had our stock of *Gardenias* a few mealy bugs were introduced with them, but by constantly syringing with clean water they were soon dislodged. I know what a trouble this pest is in many places, but venture to think I should soon put an end to them if I had to deal with them.—J. MERRITT.

LILIUM SZOVITZIANUM

AMONG hardy bulbous plants the Lilies have long stood pre-eminent for their beauty and stately grandeur, and recent introductions have invested this genus with much additional popularity. Few

Fig. 57.—*Lilium Szovitzianum*

of the more recently introduced species, however, exceed in interest *L. Szovitzianum*, first cultivated in this country under the name of *L. colchicum*, by Messrs. H. Low & Co., of the Clapton Nurseries.

In the case of strong bulbs the stem reaches the height of from 3 to 4 feet, and yields from six to ten drooping flowers disposed in a scattered raceme. In the fully developed blossom the petals are more revolute than in the figure. The colour is a brilliant citron yellow speckled internally with purple crimson, and stained at the base externally with dull purple. The flowers exhale the most delicious and powerful fragrance, perceptible at some distance, and it is in fact a question whether any other of the numerous species of this genus exceeds it in the sweetness and diffusiveness of its perfume.

The foliage is scattered, broadly lanceolate, smooth above, but paler and somewhat hairy on the under surface and on the margins. Bulb rather large with yellowish scales. By the best authorities this plant is regarded as but a variety of the *L. monadelphum*, from which it is distinguished by its stamens not being united at the base, by the red colour of its pollen, by its longer style, as well as by some other minute characters. Like most of the species it is quite hardy against cold, and will succeed in any good substantial garden soil as well as in peat, but is liable to suffer from excessive wet, and precautions should therefore be taken to insure thorough drainage. Should the conditions of local climate render it desirable protection against heavy rainfalls may be afforded by placing over the bulb a large inverted flower pot, the opening being closed in wet weather.

Owing to the somewhat slow rate of increase of the bulbs of this

genus, new species are less rapidly disseminated than in the case of plants readily propagated by seeds, and *Lilium Szovitzianum* is therefore, in common with several other recently imported species, rather rare and expensive. It is true that most, if not all of the Lilies, ripen seed under favourable circumstances, which vegetates quickly if sown as soon as gathered, but several years usually elapse before the bulbs are of sufficient size to flower.

Notwithstanding this drawback, however, we do not hesitate to recommend to those of our readers who may be endowed with a sufficient stock of patience the propagation of the Lily tribe by seed.—W. T.

CHOICE BULBS.

IXIOLIRION.

IXIOLIRION MONTANUM.—This is a most beautiful hardy bulb from Syria, but being yet so scarce in Europe, it deserves the treatment and care of the half hardy-race. It goes to rest in winter, rises in spring, and flowers with us in May under the same treatment as the Squills—that is, in any light rich border. The bulb is not much larger than that of a strong Dutch-grown *Crocus*. The stalk is from 1 foot to 18 inches high, bearing long narrow leaves and bracts; the flower stalk, or peduncle, rises from these bracts near the top, and some of them are terminal from a cluster of bracts, and they generally come in pairs; the colour is a brilliant blue. Altogether, it is a fine thing for the borders in May. Col. Chesney met with it in great abundance in Palestine and other places in the east, flowering in April, and his account of it led to the supposition in this country that it must have been the "Lily of the Field" referred to in the Sermon on the Mount. The White Lily (*L. candidum*) could not be the one alluded to, as was long believed, because none of the multitude could know that plant, it not being a native of any part of Syria. The "Lily of the Field" is now, by common consent, believed to be the scarlet Chalcædonian Lily, which grows in abundance about Galilee and all round those parts.

IXIOLIRION TARTARICUM.—This is rather smaller in all the parts than *montanum*, and there are slight differences of botanical separation between the two, yet all that may have been owing to the difference of soil and situation where this was found on the Altai range.

IXIOLIRION SCYTHICUM.—This is another of the forms, but a much smaller plant than the other two. They were all referred to *Amaryllis* by those botanists who first discovered them, but Dr. Fischer of St. Petersburg divided them from that group and named the genus. The three are probably in the Russian botanic collections; they are well worth inquiring after. Some of our consuls in the east might fish them out of the troubled waters after political storms subside. What a pretty group these *Ixiolirions* would make in a border, with such blue flowers as *Camassia esculenta* from North America, the *Cummingsias* from Chili, the *Dianellas* from New Holland, and the Squills of our own land.

LEUCOCORYNE.—This genus was separated from *Brodiaea* by Dr. Lindley chiefly on account of three of the stamens being barren. Two of them, odorata and alliacea, have white flowers about the size of *Crocus* flowers, and *ixioides* is a light blue flower, as pretty as anyone could wish for. They are natives of the south of Chili, and all but hardy, and also all but impracticable to keep any length of time under ordinary cultivation. There are some flowers from Texas which seem on a par with them, the *Cobæas* and *Pentstemon*, for instance. Extreme cold at the roots when they are growing, very warm overhead at the same time, and a scorching heat both for top and bottom when at rest, are the conditions under which they flourish in a state of nature. Mr. W. Rae, the collector sent out by the Horticultural Society, found *odorata* in bloom high up in the south of Chili, where the snow had melted only a few days before.

No gardener has ever yet been able to cultivate the Cloudberry as a fruit plant. The fruit is about the same size, shape, and colour as the Roseberry Strawberry. Few gardeners can manage some *Pentstemons* and *Cobæas*; and, I believe, fewer still the *Leucocorynes* and bulbs of such habits. I have grown *ixioides* myself as well as it ever was or will be, by placing the bare bulbs on a slate shelf covered with an inch of sand all over, and from end to end, the sand being constantly wet all the summer from watering the pots of other plants which stood on the stage.

LIBERTIA.—These are not actually bulbs, but they look as if they ought to be bulbs, and might be grown in a border without prejudice to a collection of bulbs. They are Iris-looking plants, with the flowers shaped as in the Peacock Iris or *Sisyrinchiums* and *Cypellas*. They grow in either peat or sandy loam; *formosa*, the Chilean plant, is all but hardy, if not quite so. The Australian ones, frame plants, that would grow and flower out of doors during the summer. Mr. Anderson, who sent home *Fuchsia microphylla*, found *Libertia formosa* in the Island of Chiloe growing down to the edge of the tide, whence he sent it and other curiosities to Mr. Low of the Clapton Nursery many years ago. *Grandiflora* is an older plant from New Zealand; *paniculata*, fine, and *pulchella*, from New Holland, are quite as gay as any of their allies, the *Moræas*, from the Cape; *paniculata*, and the snow-white flowers of *formosa* would make a desirable cross, besides rendering the panicked breed more hardy. It will be difficult to find them in collections, as they go under various names, as *Sisyrinchium*, *Moræa*, *Marica*, and *Iris*.

MARICA.—This genus, with its beautiful ephemeral flowers is also out of its place here. They are neither bulbs nor half-hardy, but stove plants, with the habits of the common Iris; yet I have seen them

growing out of doors in summer, and I believe the greenhouse is the proper place for them during seven or eight months in the year. They all require strong, rich loam, and in that the greenhouse is too cold for them in winter; and in the spring they delight in the strong moist heat of the stove up to May. *Marica cœrulea* and *Northiana* are two as beautiful flowers as we can grow, but, unfortunately, they only last a few hours, and only two or three in a day, although strong old plants of them keep throwing up a daily succession of them for some weeks.

MASSONIA.—The only beauty in all the *Massonias* is in their broad recumbent leaves, two of them only coming at a growth or in one season. These lie flat on the pot or border, right and left, and from between them rise a host of small white flowers in a cluster, with hardly the semblance of a scape or stalk. *Angustifolia* has the leaves upright, and not so broad as in the others. *Daubenyas* are only coloured *Massonias*, as far as gardeners are concerned. All of them delight in rich sandy loam, and grow in winter with us.

MELANTHIUM.—This has been an ill-used genus; after being named from the dark and dingy flowers, the species with such tints have been weeded out of it, and named *Wurmbea*, yet no one sees *Melanths* in cultivation in these days; at best they are only botanical plants, with *Ixia*-like leaves, short spikes of small inconspicuous flowers, and slender bulbs, requiring about equal parts of peat, and loam, and pot culture.

MILLA BIFLORA.—This is really a very beautiful plant, with large white flowers as pure white as snow; they last a long time, and come in succession, and they are as hardy as to live out of doors with a slight protection. The name *biflora* is a very great mistake, by *Cavanilles*, I believe. I never saw one without four flowers in the umbel, and the peduncle is 3 or 4 inches long. The Horticultural Society introduced it from Mexico, and spread it far and wide among the Fellows; and if ever a bulb was worth caring for this is one; it lasts a long time in bloom, and is more fitted for a south border than a pot, being long-legged and the parts slender. It will grow in any good light soil all the summer, and go to rest for five months in the winter. The other one, called *uniflora* I think, has not been much tried. I think there is some mistake about the naming of it.—C. B.

TREE CARNATIONS.

VERY rarely are Carnations grown well in pots in private gardens, and many plants are annually conveyed to the rubbish heap through mismanagement. Failure does not so often result from insufficient experience up to the time it is necessary to house them as by the want of suitable accommodation for them afterwards. Another and probably the main cause of failure is due to the supposition that a profusion of fragrant flowers will be produced in succession from the time they are housed through the winter and spring months. The system of treatment pursued to accomplish this soon destroys the health of the plants, and failure is the result before the spring months arrive. To maintain a good supply of flowers from the present time until the end of spring a large stock of plants is required, for a few will yield more flowers after the middle of February than a large number will from now until then. From a good stock of plants in a suitable position solitary flowers may almost daily be cut from the time of housing them until they are produced plentifully about the time named, but from ordinary plants they cannot be had in any abundance.

It is very frequently forgotten that the *Carnation* is a hardy plant. Any system of forcing, however gentle, during the dreary months of winter, very quickly runs up the growths of the plants weakly and destroys them after producing a few small flowers. Those who attempt to force Carnations to flower during November, December, and January must be prepared to sacrifice the plants, for they are very little good afterwards, and will not yield in the end one-twentieth the quantity of blooms that they are capable of doing under natural treatment.

Carnations, after they are housed, may be stood in a vinery from which the foliage has been removed for a time, but they will not long continue satisfactory in a makeshift position. If numbers of plants are grown they should have a house to themselves, or the lightest and best side of the house if insufficient to fill the whole space. Wherever they may be placed the treatment and conditions of the house they occupy should be arranged to suit them. From the time the plants are housed they should have a light position, not too far from the glass. This treatment must be continued through the winter, and fire heat only employed to maintain an average night temperature of 45°, and occasionally during dull weather to evaporate damp. The growth during the winter months is almost at a standstill, and employing fire heat is injurious. Under the conditions advised they will continue growing slowly, and when the days lengthen with increased light and heat thin shoots will rapidly strengthen, and a large number of fine flowers will be the result in succession for a long time.

During the winter Carnations require careful watering at their roots; the soil must not be saturated, or the foliage will soon turn a sickly yellow colour. On the other hand, they should never be allowed to suffer by an insufficient supply of water or the roots soon perish. Strong supplies of liquid manure are also detrimental to them, but given in a weak state and judiciously it will prove the reverse. Clear soot water has a very beneficial effect upon the plants and quickly tells upon the foliage. Weak liquid made from cow manure is also good for them. In addition to the soot water we have found nothing better for them than

light applications of artificial manure applied to the surface about once a month.—LANCASTRIAN.

HARDY FRUIT GARDEN.

LET planting be now done as expeditiously as possible, but let it be done well, and with a clear end and aim kept fully in view, so that every possible advantage may be given to the trees, and a strong growth of root and branch insured next season. "When shall I get some fruit?" is, we fear, more frequently the thought of the planter than, "How soon will the trees be established and growing freely in the soil?" Remember, that for a fruit tree to bear really good fruit it must lay well hold of the soil and its roots be in full activity. To buy trees "well set with fruit buds," and to allow them to bear as much fruit as possible the first season after planting, is to run a serious risk of crippling them for some time afterwards. Repeatedly have we heard it said of newly planted trees at midsummer, "How can much growth be expected yet when they were only planted last autumn?" Yet we must again insist upon it that a young fruit tree has only to be planted well and it will grow as freely the first season as in any year of its existence. Let us be satisfied with nothing less than this, for we certainly cannot afford to lose a year's growth. The points of importance are healthy robust trees, fertile well-drained soil, as little exposure of the roots to the air as is possible in the transplanting, not to bury the roots deeply, but to spread them out at full length, to work the soil carefully in amongst them, to press it by treading firmly about them, to make fast the stem so that the roots cannot be loosened in the soil, to have not more than 6 inches of soil upon the upper roots, to apply a mulching 6 inches deep of half-decayed stable, piggery, or farmyard manure when the planting is done, and at the same time to prune the branches so that the sap may flow into the buds, or rather into the shoots springing from them to form the head of the tree, and not into growth that has to be cut off. In a well-planted tree branch and root-growth maintain a tolerably even balance, so that a glance at a tree is sufficient to show us what is taking place in the soil. The best time for planting is certainly during the next three weeks. It may be done throughout winter, but not under such favourable conditions as at the present time, and therefore with less certainty of success. However apparently trivial any of the cultural points enumerated may appear, every one of them is important, and must be considered as indispensable to success. Perhaps surface-dressing with manure is more neglected than anything else, and yet how important it is that the soil should be kept moist, and that excessive evaporation should be checked! To every planter we say, then, Get a clear knowledge of the conditions necessary to success in your work, and see that not one of them is wanting.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early House.*—The trees from which ripe fruit is to be gathered early in May onward should now be examined and receive their final pruning, but where this was carefully attended to so soon as the trees were cleared of their fruit it will be a light affair. The trees should be washed with an insecticide carefully and effectually, repeating it if the branches are infested with scale. Prior to this the wood-work should have been well washed with soap and water, and if necessary paint the trellis and the interior of the house before the trees are tied in. An impression prevails that casting the buds is caused by the imperfect ripening of the wood, but this is foreign to our experience, and so far from this being the case in early houses it generally happens that the soil gets dry or the trees receive a check before forcing is commenced. To counteract the tendency to over-development of the buds and insure a thorough moistening of the soil all early houses should have portable roofs, so as to afford the trees the full benefit of the autumn rains. The lights may be painted and prepared for placing over the trees, but they ought to be placed in position before the middle of November, as any excitement now followed by a check next month may cause the trees to cast their buds when they ought to begin to swell.

Succession Houses.—Although the wood appears quite ripe and the buds are prominent and abundant, the trees, no doubt owing to the rains, are holding their foliage well, but the recent frosts have caused the leaves to assume their autumn tints and are falling freely. When this is the case no time should be lost in proceeding with lifting, root-pruning, and replanting. Provide free drainage, employing good loam from an old pasture with a rather free admixture of lime rubble and charred refuse. Keep the roots near the surface, and make the soil firm as the work proceeds. Although Peaches and Nectarines will grow in almost any fresh well-drained soil they do best in a compost that offers some resistance, and does not soon become dry, and in such they always set, swell, and finish the finest fruit.

Pruning.—Years ago every shoot was shortened back to from 12 to 18 inches in length, but of late years the young shoots are left three times those lengths and ripen a good fruit to every foot length of wood laid in; in fact, we have had shoots 5 and 6 feet long ripening as many fruits, those from the extremity being as fine as that only a few inches from the base. A great change has been effected in the training of young

trees. A tree a year old, or one year's training allowed to extend, will give the first year a breadth of at least 6 feet, and instead of having a few gross shoots to cut away in the autumn all are fruit-bearing wood well studded with triple buds, and a fair crop insured the following season; all danger of gumming is avoided, and a good-sized trellis may be covered in three or four years. Pruning is reduced to a minimum, disbudding being the most important matter in the after management of the trees. With due care not to overcrop, a Peach to every square foot of trellis covered with foliage being a good average crop, and quite as much as can be secured in a succession of years. The other main point is not to lay in too much wood; two shoots to every foot will give abundance to select from, or one bearing and the other to take its place is all that should be laid in, preventing anything approaching crowding, diminishing the labour, and improving the quality of the wood from which the succeeding crop is to be gathered, as the main point in extension training is thorough exposure of the wood to light and air.

Late Houses.—Trees in late and unheated houses will require a dry atmosphere, with a free circulation of air to harden the young growths. Remove every shoot that will not be wanted next season, particularly the gross watery growths that are not likely to form flower buds. Old trees that carry good crops of fruit and receive annual attention to the roots in top-dressing, do not, as a rule, make too strong wood; but vigorous young trees are not so readily kept within bounds, as they persist in making late growth. Where this is the case the strongest shoots should be pinched, and a trench be thrown out as deep as the roots at a distance from the base of the stem that will insure shortening the strongest roots. The trench should be left open for a fortnight or three weeks, and may then be filled in and the soil made firm.

CUCUMBERS.—When the weather is wet and cloudy, the atmosphere surcharged with moisture, the plants require special treatment. Atmospheric moisture at such times must be reduced to a minimum, and air admitted very cautiously, otherwise mildew will be likely to attack the plants, which should, upon its first appearance, be dusted with flowers of sulphur, after which the house should be kept rather dry and airy until the disease disappears. In bright weather a more genial condition of the atmosphere must be maintained by damping occasionally, especially at closing time, but for the next three months a somewhat dry atmosphere should be maintained. Do not allow the fruits to remain on the plants a single day after they have attained a suitable size for the table. Placed on the stem end in saucers containing about an inch depth of water in a fruit-room, they will remain useable for several days. Thus relieved of the fruit, the sap will be diverted to swelling and finishing the younger and smaller fruits, which is a practice that ought always to be practised during the whole of the fruiting period of the plants. The night temperature should range from 65° to 70°, falling to 60° in the morning of cold nights, keeping at from 70° to 75° by day with fire, running up 10° or 15° with sun heat. Whatever ventilation is given should be in the early part of the day, never lowering the temperature, avoiding cold currents, and closing early, so as to husband the sun heat as much as possible.

The linings of dung frames will now require to be attended to regularly by having them made up weekly or fortnightly, according to the necessity of the case, and the lights should be covered with double mats at night. Mildew and canker may be destroyed by the timely use of sulphur for the mildew, and quicklime well rubbed into the parts affected with canker.

PLANT HOUSES.

Tea Roses.—Plants potted and treated as advised some time ago for producing blooms until Christmas should be placed in a suitable house at once. Many of them now possess a good number of small flower buds, while others have started freely into growth. If these are placed in a light house where a night temperature of 50° to 55° can be maintained, with a rise by day of 5° or 10°, the buds will soon commence opening, and during the autumn months will be highly esteemed. If there is any trace of aphides upon the plants when arranged in their winter quarters light fumigations with tobacco smoke will be needed. It not unfrequently happens that after the plants have been standing outside that small specks of mildew are visible on the young foliage. This must be destroyed by syringing with a solution of softsoap, 1 oz. dissolved in a gallon of water, to which one handful of sulphur has been added. If the Roses are well syringed with this solution and the sulphur allowed to remain upon them for a few days before being washed off all trace of mildew will disappear. Afterwards syringe in the morning only on fine days with the softsoap solution so frequently recommended. Supply water carefully, and all that were recently potted will need neither liquid or artificial manure. Plants with their pots full of roots may have weak stimulants. When admitting air every care must be taken that cold draughts do not strike upon them, or the young shoots and foliage will soon become affected by mildew. The house in which they are grown should be kept perfectly close and a little fire heat applied during cold bad weather. Young stock rooted from cuttings in spring, and now in 6 and 7-inch pots for supplying flowers at this season of the year, should be treated as advised for the others.

The Rose House.—In gardens where a house is devoted to Tea Roses for yielding flowers from Christmas onwards it is no position for the plants grown in pots for flowering up to that period. In this structure the Roses that furnish the central bed, the front, and rafters are planted out, and must still be kept perfectly cool by allowing the ventilators to remain open day and night for a few weeks longer. They should now be pruned. Cut out weak puny old wood that was laid in last year, and furnish the trellises again with the ripest and best wood that has been made during the year. Where the object is to obtain numbers of buds or cutting in preference to a limited number of large blooms do not

practise a very close system of pruning. After the removal of the wood indicated only take off unripe ends. After the house has been thoroughly washed or painted tie the plants into position ready for starting, a little of the surface soil of the borders being removed and top-dress with equal portions of good loam and cow manure that have been stacked for some months. Previous to top-dressing the borders it is a good plan to scatter thinly over the surface of the border a few half and quarter-inch bones. If red spider, aphides, or mildew be present destroy them before the borders are top-dressed. The soil should be kept rather dry until the house is closed for starting them into growth, when the whole of the soil about their roots must be thoroughly moistened with warm water. Plants subjected to this treatment will soon plump up their buds after the house is closed and break into growth without fire heat except in very cold weather.

Hybrid Perpetuals.—Those established in pots may remain outside until the approach of frost, unless the weather is mild and it is necessary to prune and house them ready for starting early into growth. All late plants should remain outside for at least the next two months. Where it is necessary to increase the stock strong plants from the outside can be lifted and placed at once in well-drained pots. The pots used may be 9 inches in diameter, but if the ordinary trade plants are purchased pots 2 inches less will be large enough. Employ a mixture of fibry loam, one-seventh of decayed manure, one 6-inch potful of soot to each barrowful of loam, and the same quantity of small bones. If the loam is of a heavy nature add to this a liberal dash of coarse sand. After potting plunge the plants so as to cover the rim of the pots, for if dry weather ensues no water will be needed at their roots. The foliage must be preserved healthy as long as possible, and if this is done a large quantity of fresh roots will be formed before it is necessary to place them in cold frames.

THE BEE-KEEPER.

SPREADING BROOD.

THE refutation of the arguments adduced by the supporters of spreading brood has been undertaken by men so eminently well fitted, both by long practical experience and knowledge of the theoretical part of bee-keeping, that until a few weeks ago I had no intention of giving my views upon the subject, although to my mind the practice has been condemned most thoroughly, if strength of arguments against it were the only consideration. Before going further we had better fix in our minds the object we have in view, which object is, so say the advocates of spreading brood, best attained by this questionable method. For myself I always keep my object in view, and carefully working to obtain the result aimed at, generally, if not always, arrive at the desired goal.

There cannot be a doubt that in the present day no man is able to hold his own without showing energy and perseverance, and in addition thrift. It may be that some men make money while others lose it, and if the case is carefully inquired into the result often shows that the cause of the failure lies at the door of the man himself, and that he and he only is to blame for the unsatisfactory results which have accrued either by "bad luck" or some other dreadful calamity. It is so in bee-keeping—one man makes money, another loses it. But to the point. The object to be attained in spreading brood is, I take it, to bring a stock forward as quickly as possible, in order to be ready to take advantage of the earliest honey flow, or, if the owner prefers it, to increase by swarming. Granted that the man who spreads brood is able to bring about this most desirable object, and to have his stocks strong, healthy, and in good condition at the end of April or beginning of May, they are, it must be admitted, in a most satisfactory condition, but for all that it does not at all follow that the only way to accomplish this admirable result is by the adoption of this troublesome and, in the hands of any but experts, most dangerous practice. If a means simpler by far, inexpensive, taking much less time, and therefore entailing little or no extra expense, can be pointed out by which stocks can be brought up to the point at which they are ready to be supered or swarmed at the same early date by a plan so simple as to be managed by the merest tyro in apiculture, and in addition so safe a method as to entail no danger of chilled brood, lost queens, or any other of the many dangers to which the spreader of brood is constantly liable, the result will be that all can be desired.

In the hands of Mr. Cowan the spreading of brood may be achieved at a minimum expenditure of time, and with the least possible danger; but how many are there who have the knowledge and experience of this great bee-keeper? Does he not himself warn us against the practice if not carried out with the greatest judgment and care? If, then, it can be proved necessary in order to prepare stocks to gather honey in supers in the earliest part of May to spread brood, it will be quite time to adopt the practice unless the disadvantages are so great as to counterbalance the advantages. That question cannot be here discussed. I maintain that exactly the same result may be achieved by attending to the following points in autumn:—

1. Every stock to receive additional bees, so that the colony is made very strong in numbers.
2. Every stock to be well fed, so that there shall be store enough to last till April at least.
3. Care to be taken to wrap up warm and keep bees dry and undisturbed, at any rate till March.
4. Good fertile queens.

By carefully carrying out these four rules the same result will follow as from the more complex method, and it will be evident that but a little extra time in autumn is required to strengthen and to feed up to the desired weight. Stimulating in spring is advocated also by some as a means of bringing forward a stock more quickly, but as far as my experience goes there is not much difference between the state of a stock well supplied with food and left undisturbed, and one with less internal supplies supplemented by dribbles in the cold bleak weather of March and April. Sugar-fed stocks, notwithstanding the Editorial in the *British Bee Journal* of 1st October last, are the choicest of stock for early summer work, and I may point out that one great and very general reason why these stocks do not come up to expectation is that insufficient bees are given. There cannot be too many; there may easily be too few. If a hive is well filled with driven bees, and fed up carefully, a result will be given even in face of the most sanguine expectations of most bee-keepers. To sum up, then, it seems to me that the advocates of spreading brood have to show

First, That their method, which for sake of argument we granted to be successful, is in reality so.

Secondly, That by no other method can the same good result be obtained.

Thirdly, That no other method so nearly approaches the spreading-brood system as to make it on account of simplicity and little expense of more practical profit than the more troublesome means they advocate. Surely there can be no difficulty in proving these three facts. It must be a very easy task if we may judge by the glowing accounts given from time to time of the great profits obtained by the advocates of this perfect utilitarian system. There can be no difficulty in quashing the arguments given of the experience of "A Lanarkshire Bee-keeper," and showing the magnificent strength of the rampart by which the advocates of the system defend themselves; for this I note that it is customary not to answer awkward questions amongst a certain class of bee-masters, and so to stifle as it were full discussion. This question ought to be considered on its merits, and it is with this desire that I have endeavoured to bring into publicity some facts which condemned the system, and to substitute a really useful and simple method of obtaining the same result.—FELIX.

WASPS.

In reply to "Basil," the best hint to prevent wasps entering hives is undoubtedly to destroy their nests, which may be easily found by close observation of the exact line they take on leaving the hive. Dusting wasps with flour on the alighting board enables us to keep an eye on them for a longer distance. If the nest is within a short distance it will not take them many minutes to disgorge and come back. I have often found nests by simply taking notice how long they were away. Wasps are most interesting insects to study. I have an excellent nest in a large glass super in full working order, which I keep for the inspection of

friends. Any nests known to exist at the present time should be destroyed to prevent the queens escaping. It is rather late, but in some warm dry places many will be found still. If the working wasps still trouble you stop up the entrances, of course giving ventilation, and place bottles half filled with beer and water sweetened with sugar, or vinegar and water and sugar.—J. HAM.

TRADE CATALOGUES RECEIVED.

Richard Smith & Co., Worcester.—*List of Plants*.
J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees, Shrubs, and Roses*.
L. Späth, Berlin.—*List of Bulbs*.
William Paul & Son, Waltham Cross, Herts.—*Illustrated Catalogue of Roses*.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Dry Vine Borders (A. G.).—The dryness of the roots to which you allude accounts in a great measure if not entirely for the premature shrivelling of the fruit. Dry soil causes the roots to shrivel, and then after water is given they are not in a condition to imbibe sufficient for the demands of the vine or fruit, and a collapse occurs sooner or later. It is the same when borders are excessively wet, causing the roots to decay. They must be in active working order for affording adequate sustenance to the wood, foliage and fruit.

Bleaching Pampas Grass (P. C.).—We believe the plumes are bleached by suspending them in a close shed, or any suitable place not in a dwelling or where plants are kept, and burning sulphur in it until the enclosure is filled with fumes, and not opened for several hours, or say till the next morning. If anyone can recommend a better method we will readily insert a description of it if obligingly forwarded for that purpose.

Roses for Market (J. S.).—The following are extensively grown to afford blooms for market:—Niphetos, Isabella Sprunt, Madame Falcot, and Génér al Jacqueminot. If they produce rather strong growths and these are matured, they are bent and trained round the plants if it is desired to keep them dwarf. More flowers are thus produced than when such growths are closely pruned and they are cut before half expanded, the great majority being required small and fresh for buttonholes.

Popular Apples (Planter).—There is something in your suggestion that "the most popular Apples are likely to be the most useful because their merits have been extensively recognised;" yet we scarcely consider the test conclusive. We name twenty-four each of dessert and culinary kinds that were the most fully represented at the Apple Congress at Chiswick, but we do not regard them as the best that could be selected, nor as even placed in the order of merit. They will still form a good collection:—**Dessert**—King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Kerry Pippin, Blenheim Pippin, Irish Peach, Devonshire Quarrenden, Sturmer Pippin, Scarlet Nonpareil, Court Pendu Plat, Yellow Ingestrie, Fearn's Pippin, Claygate Pearmain, Worcester Pearmain, Margil, Wyken Pippin, Cockle Pippin, Court of Wick, Red Astrachan, Adams' Pearmain, Mr. Gladstone, Golden Pippin, Mannington's Pearmain, Gravenstein. **Culinary**—Lord Suffield, Dumelow's Seedling, Kewwick Codlin, Warner's King, Blenheim Orange, New or Winter Hawthornden, Cellini, Ecklinville Seedling, Stirling Castle, Hawthornden, Manks Codlin, Golden Noble, Cox's Pomona, Alfriston, Emperor Alexander, Northern Greening, Tower of Glamis, Mère de Ménage, Beauty of Kent, Lord Derby, Yorkshire Greening, Annie Elizabeth, Norfolk Beefing, and Loddington Seedling.

Improving Lawn Tennis Ground (Mrs. Watson).—It is not unlikely the lawn requires draining, and if so the first step to take is to put in drains 6 or 7 yards apart and 18 inches deep, with proper falls into a main drain and a clear outlet for the water. Three-inch pipes will be sufficient, and they should be covered 6 inches deep with rough cinders or gravel to render them permanently effective. Drainage, however, may not be needed. Of this you ought to be the best judge; but whether it is done or not, a heavy dressing of fresh soil, with a liberal admixture of manure, lime, and wood ashes spread over, so as to almost cover the grass, cannot fail to be of great benefit. Before applying the dressing comb off all the moss you can with a small sharp-toothed rake. This you may do at any time when the ground is dry very early in spring, and later, when the weather is genial, sow thickly seeds of a renovating lawn mixture. Rake it in and roll the ground lightly, and you may expect a greatly improved lawn a few weeks afterwards. If you state the extent of the ground to any seedsman or firm who deal largely in grass seeds the proper quantity of a snitable mixture will be sent to you. If the lawn is full of deeply rooting weeds you had better dig it up, forking and picking out all the rubbish, then make it level and firm, and sow it as before advised. In this way you may form a cleaner and better lawn than by taking up the old and laying down fresh turf as you propose, as, however clean the new turf may be, the roots of the weeds left in the ground will grow, and the new turf will soon be as unsightly as the old.

Black Morocco Grape (S. N.).—Your Grape is the Black Morocco, which was sent out some years ago as a new variety under the name of Kempsey Alicante. It is a late Grape of good quality, and requires a warm temperature. When well grown, which is seldom, it is a fine Grape. Its great fault is being a bad setter, and it is only by gently drawing the hand over the bunches when in flower to remove the moisture that exudes from the stigmas, then apply pollen from another variety, if it is obtainable, to insure full bunches. If fresh pollen cannot be had the berries may set fairly without under favourable atmospheric conditions. It is, however, essentially an uncertain Grape, and not half so reliable as the Black Alicante, which is one of the easiest of varieties to grow, as the other is one of the most difficult.

Pruning Clematis Lucie Lemoine (Idem).—This variety belongs to the Florida section and flowers in early summer. The object of the cultivator should be the production of free healthy growth under the full influence of light and air, and only remove the unripe portions with any old growths that have become weak, as the best flowers are produced on good well-ripened young wood. Your plant is probably "sickly" by defective root-action, and fresh soil may be needed. You do not say whether your plant is in a pot or not, or under what conditions it is grown, so we are unable to give you more precise information. You may, however, read the reply given to another correspondent about its culture. Chip punnets, we believe, can be had from Mr. P. Nicholls, 377, Goldhawk Road, Hammersmith.

Mealy Bug in Vineries (J. L. A.).—This pest is the worst the Grape grower has to contend with in vineries, as it destroys the appearance of the fruit; and the measures necessary for the destruction of the insects cannot well be employed when they are the most active without injuring the Grapes. The mealy bug is most active during the growth of the Vines, remaining dormant during the winter or resting period of the canes, and is called into activity soon after fire heat is applied, which depends of course upon the time the fruit is required ripe. It is most successfully contested when the Vines are at rest. In your case we advise the Grapes to be cut at once and bottled, which will give you an opportunity of attacking the bug before it becomes ensconced in its winter quarter—i.e., beneath the bark, in the holes and crevices of the rods, also woodwork, &c., of the houses. The Grapes being cut syringe the Vines thoroughly both ways with petroleum at the rate of a wineglassful to three gallons of water, which should be kept mixed by one person stirring briskly with a broomhandle, whilst another is applying it to the Vines. It must be done thoroughly so as to saturate every part of the Vines, and not only those, but every part of the house. If the foliage of the Vines is difficult to reach on their upper surfaces they must be loosened from the trellis and lowered so that no part of the leaves escapes wetting with the petroleum water. Allow the foliage to become dry, and then repeat the operation. The leaves being somewhat mature will not be injured by the petroleum. When the foliage is mature the operation should be again repeated as before, and then matters may rest until the time arrives for applying fire heat, when the Vines and house should again be syringed with the petroleum, care being taken to perform it before the eyes have broken. This is a drastic remedy, you may say. It needs one, as no half measures are of any avail. During the growth, so soon as the Vines show leaf, a sharp look-out should be kept for any of the insects that have escaped the dressing, and of course destroyed, which will prevent propagation; and if any escape and get into the branches they should be destroyed by a small brush or camel's hair pencil dipped in methylated spirits.

Clematises for Conservatories (E. Willing).—We cannot better answer your questions, which are not particularly clear, than by citing from Messrs. Moore and Jackman's work on this beautiful family of plants:—"For conservatory decoration the varieties of *C. patens* and *C. florida* are infinitely superior to the rest as objects of ornament. The plants may be grown as pot specimens with excellent results. They may also be planted out in the conservatory, where they are especially fitted for training up the pillars or over the trellising fixed for covering walls, provided the situation is not too much confined and shaded by the other occupants of the house. They are, doubtless, more appreciated when grown in these positions, or in glazed corridors, than when grown outdoors, for not only are these earlier flowers more highly prized than the later ones, but the blossoms themselves are occasionally liable to suffer injury should severe spring frosts occur during the time they are open. The plants themselves are, however, perfectly hardy, and are really good wall creepers, so that but for this limited risk to the flowers themselves, no better or more interesting subjects for such positions could possibly be selected. For pot-culture, then—and supposing young plants are obtained to commence with—they should be shifted about March into larger-sized pots, using a rich loamy compost, and paying especial attention to drainage. If the plants are well rooted at the first, and in a healthy condition, the pots may be some two or three sizes larger than those in which they have been wintered, as this bulk of good soil will induce a vigorous growth of the branches during the summer, and preclude the necessity for a second potting later in the season, which might not be beneficial. The plants should flower well if grown in 10-inch or 12-inch pots. The chief object should be to induce the development of a strong shoot or shoots, and to get this young growth well ripened by exposing it fully to light while it is progressing, and by so ordering the root-treatment, and the supply of water, as to bring about a cessation of active growth towards the end of the summer. Thus developed and matured, the shoots are prepared to give forth their lovely flowers at the proper time in the ensuing spring. While growing, the young shoots cannot be better placed than when fastened perpendicularly to a string or wire in the full sunlight, but these shoots should be trained into the form required while they are still dormant in winter or early spring, so that the young flowering growths may dispose themselves naturally before the blossoms expand. Cylindrical or balloon-shaped trellises are the most convenient and suitable for specimen plants of this character. Plants thus grown, and thus trained, form fine objects for home decoration, as well as admirable subjects for the earlier or spring exhibitions. The natural period for the blossoming in a cold house entirely without artificial heat, is about the end of April or the beginning of May; but by the aid of gentle heat they may be had in flower earlier. The temperature should not, however, be allowed to range higher than from 45° to 55°, for if higher than the latter the flowers will not be of their true or natural colour. A rich light loamy soil, and an annual mulching to secure a renewed and vigorous summer

growth, are required; while the pruning must consist in the removal of a portion of the old flowering wood, sufficient to give the plants a new start, in order that young flowering wood for the following season's bloom may be secured."

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*G. R. J.*).—1, Gloria Mundi; 2, Reine de Canada; 3, Beauty of Kent. (*Caterham*).—The large Pear is General Todtleben—only a baking Pear with you, as it does not appear to ripen on your soil. The small one is not known. (*A. J. Brown*).—1, Blenheim Pippin; 2, Dr. Harvey; 4, Fearn's Pippin; 5, Lewis' Incomparable; 6, Duck's Bill. (*J. E. C.*).—Mère de Ménage. (*C. T. H.*).—1, Mère de Ménage; 2, Dumelow's Seedling; 3, Pear Calebasse. (*Constant Reader*).—1, Early Nonpareil; 3, Yorkshire Greening; 4, Nonesuch; 5, London Pippin; 6, Greenups Pippin. (*Somerset*).—No. 1, quite passed; 2, Vicar of Winkfield; 3, Figue de Naples; 4, Brown Beurré. (*G. B., Guildford*).—1, Glou Morceau; 3, Verulam; 4, Beurré Diel; 7, White Doyenné; 9, Gansel's Bergamot; 10, Vicar of Winkfield.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*C. H. S.*).—1, *Begonia semperflorens*; 2, *Dracæna*, but too immature to be determined; 3, *Adiantum cuneatum*; 4, *Pteris serrulata*; 5, *Onychium japonicum*; 6, *Phlebodium aureum*. The numbers had become so nearly obliterated, that we are not sure if the above are all in their proper order (*A. L.*).—1, *Pyrethrum uliginosum*; 2, *Rudbeckia speciosa*.

COVENT GARDEN MARKET.—OCTOBER 21st.

COBS selling freely, with a tendency to rise. Good Pines are now in demand, our market being nearly clear.

SHELTER FOR LIVE STOCK.

Will the time ever come when the shelter for the whole of our farm animals will be regarded as an indispensable necessity? Yes, we believe it will, when farmers are able to grasp intelligently the full significance of the term, and can understand its value. That exposure to cold and wet can be borne with apparent impunity by many animals is doubtless true enough; but such exposure is a piece of careless extravagance, in which we certainly cannot afford to indulge in these hard times. We may give an animal plenty of the best food, and yet it may not grow and lay on fat so fast as we know it ought, simply because more of the food goes to sustain heat in its body than need be if it had protection from cold and wet. In a recent visit to an off farm we found a fine herd of twenty bullocks out on the home close pasture. Now, it was raining hard with a high north wind, and the day was, in point of fact, just one of those bitterly cold wet days which so often prove fatal to young cattle at this season of the year. We went out among the

bullocks with the bailiff, and tried to convince him of the mischief arising from such exposure; but he evidently could not or would not see it, pointing to the eager way in which they were eating the grass as evidence that they did not suffer from the weather. Well, it is not an easy matter to overcome prejudice and fondness for old customs, and the only method in such a case is to give explicit orders that the cattle shall be kept in warm yards on such days.

The really practical point of view of this important matter is not how much exposure to inclement weather animals can bear, but rather what benefit is to be derived from shelter. To begin with, we must remember that a certain degree of delicacy is inseparable from the condition of domestic animals, and the necessity for shelter ought to be a foregone conclusion. We are bound now to strive for small profits and quick returns. To bring bullocks into growth and condition for the butcher at an age of eighteen or twenty months instead of three years, and sheep in seven or eight months instead of two years, there must be no cessation of growth or falling off in condition. As a means to this end we must add materially to our provision of all kinds of shelter. In every meadow there must be one or several large spacious lodges with yards or enclosures in front, with boarded sides to break the force of high winds. Let the lodges be boarded at the sides, the only opening being a doorway 6 or 8 feet wide. Always avoid narrow doorways to cattle lodges. Many an animal has sustained serious injury in the rush through them which occurs when the herd is startled, and the mere sight of a stranger will do this. Such lodges and enclosures afford shelter both in winter and summer. Once let cattle have access to them and they will invariably turn into them for shelter from heat and flies in summer, and from cold and wet at all seasons of the year. Especial care must be taken to raise the yard bottoms and lodge floors with some hard substance above the surrounding surface, so as to have them firm and well drained. We ought never to suffer cattle to lie down upon a bed sodden with moisture, or to stand for hours in winter in several inches of water. The same remarks apply with equal force to large cattle yards and lodges. Commodious buildings, snug enclosures, well-drained yards, plenty of soft dry litter are to be regarded as indispensable. In the yard for dairy cows there must be plenty of both open and closed lodges, no delicate cows being left out in the yard at night from the present time till the cows go out on the pastures again next spring. Let this be a fixed rule, and do not leave it to the judgment or fancy of the cowman. How can a farmer sleep soundly who has left such matters to chance or the discretion of an ignorant, thoughtless servant?

Turning now to the flock, we may well inquire into what has been done for it in the way of shelter. Folding on Turnips, Cole, and Mustard is now being done. We have heavy rainfalls almost daily. Can anything be more wretched than the plight of a flock kept standing for hours, or rather day after day, in several inches of mud? If folding upon arable land is unavoidable let it be done by day, removing the sheep at night to a sound dry pasture with lodges and enclosures with hard raised floors. "Bosh!" do you say, my good friend? Assuredly not. Have you never heard the distressing cough of many a sheep at this season of the year? Certainly you have, and if you claim to be a practical farmer you ought to have thought out the cause, found a remedy, and applied it. We ought not to suppose that a certain per-centage of loss is inevitable in a flock, but rather to make close inquiry into the cause of every loss, and to do all we can to prevent a recurrence of it. Do not keep weakly or over-age sheep, but always weed out all such from the breeding flock every year, retaining only young healthy strong animals which, with ordinary care, are likely to pass through ordinary exposure unharmed.

Of pigs it is often said with truth that one may force them in growth and condition more speedily than any other animal. Piggy is undoubtedly a kindly creature, with an

enormous appetite and wonderful digestive powers, but he suffers from cold perhaps more than any other animal. We may claim for him, in the interest of his owner, a sound roof and plenty of warm dry litter; and not without reason, for we have seen pigs in wretched plight clustering together for warmth upon a miserable wet, muddy bed under an apology for shelter in the guise of a few faggots, which certainly were the reverse of a dry roof.

WORK ON THE HOME FARM.

Frosty nights gave the signal for the clearance of Mangolds from the fields. The work is begun, but it is much hindered by wet days. No opportunity must be lost of pressing on with it both to get the roots heaped or housed before severe frosts set in, and to clear the land for Wheat-sowing as early as possible. Rye has come up nicely, and Winter Oats are also fast coming through the surface. Ploughing for Wheat and carting corn to market still goes on as fast as possible, but wet weather proves a sad hindrance to corn-threshing as well as field work. But little way has been made in cleaning foul stubbles this autumn, except where prompt action was taken immediately after the corn was carried to the rick yard. But it was just then that horses were so much in demand that our full strength could not be put into the stubbles. There is also an objection to ploughing or horse-hoeing before pigs and sheep have been run over the stubbles; but by taking field after field in succession it can usually be managed. We have had to leave one very foul field alone till we get more settled weather. It is good mixed soil, and we hope to get it clean next spring in time for roots, or Maize, or Mustard—anything rather than a long fallow. We have several farm roads in bad order, and have given orders that on every favourable occasion stone or gravel shall be accumulated for repairs during winter. Ditch-scouring and hedge-trimming is now being done, and due care taken to make clear the mouth of every field drain whose water is discharged into any ditch. This at least should be done annually, for without a system it is precisely one of the little matters—trifles, so-called, that are liable to be overlooked. Some miles of ornamental clumps and belts are in course of being thinned. We devoted several days to marking the trees before the pressure of Michaelmas work was upon us, and now the men are set to cut down trees and make faggots by piecework. There is nothing like piecework both for master and man. It puts an end to all eye-service, and if a man is worth his salt he will exert himself to earn a few extra shillings in this way. To set a body of men at work by the day in woods and plantations away from close supervision is wrong, and it never answers. Let a labourer feel that he has an interest in every stroke, and he will strike home. Only take care that he does his work aright. The shirkers are keen to recognise ability in a master, and either soon cease to be troublesome, or they have to be got rid of. Of other piecework land draining is also begun; but in one instance the subsoil was so hard that we had to withdraw the men for awhile. Two-inch tile drains will be made as far as is possible in wet land this winter.

KINVER GIANT WHITE WHEAT.—Referring to the article on "Wheat Sowing," page 351 of your Journal, will you kindly permit me to point out that your able correspondent has omitted to mention the name of the variety of Wheat which was referred to by Mr. Evan Baillie of Pilleigh as producing the large yield of 47 bushels per acre. The variety in question was Webb's New Kinver Giant White Wheat, and if you would kindly note the same in your next issue it would no doubt be much appreciated by your readers, who, I am sure, are always anxious to hear of new varieties of sterling merit.—W. B.

REMARKS.

11th.—Fine, but not very bright.
12th.—Fine and bright, but spots of rain about 11 A.M.
13th.—Dull and showery.
14th.—Dull and damp morning; wet afternoon.
15th.—Fine, bright day; damp drizzle in evening.
16th.—Fog early, then fine and bright.
17th.—Foggy morning; fair afternoon.

A damp cool week, the temperature still falling. With the exception of the week ending September 19th the mean maximum temperature has decreased without interruption and by very nearly equal amounts since August 15th. Of course a decrease of temperature in the autumn months is the usual rule; but it is very rare for it to be so regular as (deducting 21° from the week ending September 19th), the following—viz., 1° 3, 1° 7, 1° 2, 1° 6 1° 3, 1° 4, 3° 7, 3° 3, and 3° 4.—G. J. SYMONS.

THE ORIGIN OF ENGLISH POTATOES.

AS is well known to readers of horticultural and agricultural literature Lord Cathcart has long taken a deep and active interest in the improvement and cultivation of the Potato. At his lordship's instigation Mr. Baker of Kew undertook a review of the tuber-bearing species of *Solanum*, which was embodied in an admirable and exhaustive paper read by him at a meeting of the Linnean Society on January 17th, 1884. "What Lord Cathcart asked for," Mr. Baker observed, "were any suggestions that a botanist might give, founded on his knowledge of the Potato plant and its geographical distribution, that were likely to be of practical value to cultivators."

After a critical examination of twenty so-called species of tuber-yielding *Solanums*, Mr. Baker could only regard six of them "as possessing a fair claim to be considered as distinct species in a broad sense," the majority of the others being regarded as forms of *S. tuberosum*, from which in his opinion "all the numerous varieties of Potatoes in cultivation originated." The six species, each having its own climatic peculiarities, are *S. tuberosum*, *S. Maglia*, *S. cardiophyllum*, *S. Commersoni* (syn. *Ohrondi*), *S. Jamesi*, and *S. oxycarpum*. In his remarks on these the prospective value of *S. Maglia* as a seed parent was first pointed out in the following words:—"As far as climate is concerned it cannot be doubted that *Solanum Maglia* would be better fitted to succeed in England and Ireland than *S. tuberosum*, a plant of a comparatively dry climate."

The differing characters of the two species, *S. tuberosum* and *S. Maglia*, were concisely and lucidly explained by Mr. Arthur W. Sutton in a letter which appeared in the *Times*, and was reproduced in this Journal, page 523, vol. ix., December 11th, 1884:—"Solanum Maglia was discovered by Darwin in the Chonos Archipelago, and is remarkable as having for its habit at low-lying marshy places near the coast, whereas *S. tuberosum*, from which the cultivated Potato springs, is a native of the higher Andes, where rain is almost unknown." From these facts the following practical deductions were drawn—"As in a wet summer and autumn the Potato disease is invariably much more virulent, while in a dry season its ravages are reduced to a minimum, it has been thought that the constitutional aversion of *S. tuberosum* to wet has probably induced its susceptibility to disease. On the other hand, it is hoped that the preference shown by *S. Maglia* for a damp soil and moist climate may lead to its being a parent of a new race of parents far more suitable to the climate of the British Isles."

With that object Lord Cathcart, determining to profit in the best manner available, from the suggestions of Mr. Baker, sent tubers of *S. Maglia* and *S. Jamesi* to Reading in March of last year, and Mr. Sutton also obtained examples of *S. Ohrondi* (*Commersoni*) from M. Blanchard of Brest. All these were well grown, and though every effort was made to cross the two latter with cultivated varieties of Potatoes, the essential differences between the plants were so great

that the attempt failed. But what is of more practical importance, three fully developed berries filled with seed were obtained from *S. Maglia* as the result of fertilisation with a variety raised by Mr. R. Fenn, and not yet in commerce. Though *S. Maglia* has been grown at Kew for upwards of twenty years, and two tubers of it were sent by Mr. Caldcleugh to the Horticultural Society's Gardens at Chiswick in 1823, and gave a yield of about 600, no instance is known of the species producing seed before. What may be the outcome of the Reading success it is impossible to anticipate. The results are already most encouraging, and may be of far-reaching importance. Lord Cathcart and Mr. Baker cannot fail to be gratified by the produce of the *Maglia* seeds, and they share the honour with Mr. Arthur Sutton in producing one of the most remarkable collections of Potatoes that has ever been arranged for examination.

From the seeds referred to twenty-eight plants were raised, and the produce of these plants, with representative examples of *S. Maglia*, *S. Jamesi*, *S. Commersoni*, and *S. tuberosum*, are systematically displayed in one of the offices in Messrs. Sutton's trial grounds. Baize-covered tabling is fixed round the sides of the building, divided with laths into as many compartments as there are varieties and species for occupying them, the first twenty-eight being the *Maglia* seedlings. When these are examined, and it is remembered they are the produce of one species fertilised by one variety, a feeling of wonder can scarcely be suppressed at the extraordinary diversity of the progeny. There is a family likeness, more or less marked, between some of them, yet all differ, and in many instances the dissimilarity is extraordinary; and, further, all differ from the parent *Maglia* as represented in a heap at the end of the room. It is purplish red in colour, the tubers, which may be described as of fair table size, being the reverse of uniform in shape. Some are nearly round, others more or less irregularly oval; some twice as long as they are wide, others knobbed and of no describable shape. They have deep eyes, and, on the whole, have a coarse appearance rather than otherwise; but their starchy quality is indicated by the rough or cracked skin. They are very dense, cook beautifully white and mealy, and the quality is superior to that of numbers of varieties in cultivation. It may be stated here that although only one cross was effected last year, this year Mr. Sutton has succeeded in crossing *Maglia* with three varieties of admitted excellence—Reading Russet, Walker's Regent, and Paterson's Victoria.

The seedlings, now on view appear to have inherited the rough skin of *Maglia*, that is all. It is true some of them are coloured; but not one of these has deep eyes like the parent, but are as symmetrical as could be desired, while the few that follow it somewhat in shape have rejected its colour and are white. In hybridising it is customary to have regard to form and habit in the seed-bearing parent, and to rely on the pollen-bearer for imparting other qualities; but here the form and character of *Maglia* are practically lost, and the dissimilarity in the growth of the plants is as great as in the configuration of the tubers, while the divergences in ripening and weight of produce are equally great.

The stems varied from 12 inches to 75 inches in height; the period of ripening extended over three months, the earliest being lifted at the end of June, the later varieties the end of September, and the yield ranged between 6 grains as the lightest weight from one plant to 2 lbs. 12½ ozs. the heaviest. It should be stated the seed was sown in March of the present year, the seedlings potted, and the whole of them planted out on June 11th. The smallest tubers are not larger than peas, the largest (only one) of good size for table, the majority ranging between the size of Damsons and Victoria Plums, those of one variety (No. 14) being the colour of that Plum. There are forty-three of them, weighing 1 lb. 7½ ozs., and the plant grew 54 inches high. It is noticeable that the taller the plants the later they were in maturing, and the heavier the yield. For instance, No 13 grew 54 inches high, produc-

ing sixty-one tubers weighing 2 lbs. 1 oz., white, of the shape of Paterson's Victoria. No. 19 grew 62 inches high, produced forty-four tubers weighing 2 lbs. 12½ ozs., blush, with eyes of the smallest and a variety of promise; this plant flowered. No. 22 grew 75 inches high, produced twenty-nine tubers weighing 1 lb. 9½ ozs., a flattish round variety with white crackled skin. The tops of four varieties were taken off and struck as cuttings with the object of increasing the stock, but the experiment failed, for the seedlings "bled and died;" but one of the plants—a cutting from a seedling—attained a height of 70 inches, producing eleven tubers, which weighed 1 lb. 2½ ozs., one of them large enough for cooking. This is a white round variety, and promises well as a cropper. All those mentioned ripened and were lifted in September. By way of contrast it may be noted that the combined produce of three plants that only grew a foot high, and lifted early, was only thirteen tubers weighing 28 grains. It is not necessary to particularise other varieties, as sufficient is said to indicate the character of these interesting seedlings.

The hope of substantial improvement rests in the production of strong-growing, great-cropping varieties of good quality, and there are not wanting indications that some such may be found in the Maglia race under notice. All past experience proves (the experience of "disease years") that of late, and consequently the most productive varieties, only those possessing inherent vigour, great leaf power, and woody upright stems, can resist the murrain, such, for example, as Redskin Flourball, Magnum Bonum, Scotch Champion, and others of similarly robust growth. It is much too soon to rejoice at the Potato disease being banished. The fungus will in all probability be seen again when climatal conditions are favourable to its growth, and it will be fortunate if varieties of Potatoes are then established that will resist its rapid increase and development. If the "fresh blood" of *Solanum Maglia* will contribute to this end, those who have been the means of its introduction will deserve well of their country. The species itself is not disease-proof, as weak plants of it have been affected; but strong plants, or varieties raised from it with more ligneous stems, may have greater disease-resisting power, and further experience with the varieties now raised and others to follow will be watched with interest by growers of Potatoes in this and other countries.

In the consideration of this question, the employment of *Solanum Maglia* as a seed parent, it is difficult to resist the impression that this species has not already had some share in establishing the present race of cultivated Potatoes. It has a much closer resemblance, both in its habit of growth and character and quality of tubers, with cultivated varieties than *S. tuberosum* has. Its improvement by cultivation in this country is much more decided than that of any other species; and it is perfectly clear that the Reading seedlings possess all the characters of English commercial Potatoes. There is nothing whatever, so far as regards the appearance of the tubers, suggestive of a different race, and there is at least a possibility of the Maglia species having been confused by old botanists with *S. tuberosum*, and consequently of the pollen parent employed at Reading being a descendant of *S. Maglia*. The published descriptions of the species Maglia and *tuberosum* in old and even comparatively modern works is very unprecise, and in several instances one might do for the other, for the sufficient reason that one writer appears to have relied on the other, at least to a very great extent.

One prominent characteristic of *S. tuberosum* seems to be pretty generally admitted—namely, the tubers being bitter, while those of *S. Maglia* are not. There is no suspicion of bitterness in the Reading stock, which is admittedly true. The tubers of Maglia already referred to as sent to Chiswick by Mr. Caldcleugh, and grown there sixty years ago, were also, according to Mr. Baker, undoubted examples of *S. Maglia*, and the figures of both of the tubers and growing stem represent the species grown at Reading much more closely than they represent *S. tuberosum*. Even the figures in both editions of Gerard's "Herbal" resemble *S. Maglia*,

especially that in the second edition by Johnson, which was borrowed from Clusius. What evidence is there that the Potato of Gerard (which he received from Virginia) was not *Solanum Maglia*? A botanist receiving a tuber-yielding *Solanum* that he had never seen before would quite naturally call it "*tuberosum*;" and it does not seem extremely probable that early explorers would pass over the coast plant called by the natives Maglia, and penetrate into the interior of the country, and only send home tubers of the true *S. tuberosum* found on the high mountain sides; as, apart from the trouble, not to say danger, involved, they would be collecting the inferior species. Caldcleugh's tubers were sent to Chiswick as *S. tuberosum*, and described as being bitter in Chili, but when grown they proved to be in flavour exactly like the young cultivated Potato. They were Maglias. The collector had apparently made a mistake, and it is at least conceivable that others may have fallen into a similar error. Even such famed botanists as Dunal and De Candolle accepted Sabine's figures of the Chiswick specimens as *S. tuberosum*. "There cannot"—to quote Mr. Baker's words—"be any doubt that they represent excellently the present type" (Maglia). Yet Mr. Baker, after all his laborious investigations and examinations of dried and living specimens, is "fully satisfied that all the numerous varieties in cultivation originated from *S. tuberosum*." This verdict may be correct, and supported by evidence that has not been made public; but at the same time it is impossible to overlook the weight of the Reading experiments, which tend to the contrary; and further, apart from possible mistakes of collectors, it must be asked, What became of the six hundred undoubtedly Maglia tubers raised at Chiswick? If, as is not unlikely, they were distributed among the members of the Society, have they left no impress on the varieties now in cultivation?

In reply to this question it may be asked in what manner their influence could be conveyed, since *S. Maglia* is not known to have produced seed before last year. And it can also be said that the flowers at Reading produced no pollen. It does not follow, however, that they produced no pollen elsewhere. As a matter of fact flowers of *S. Maglia* have produced pollen which has been gathered by Dr. Hogg, who grows the true species, so that it is not impossible that seminal changes have resulted from the casual distribution of the "six hundred," or from the introduction of *S. Maglia* under the name of *S. tuberosum*.

But quite apart from that contingency (fertilisation), changes can be effected by the sporting of growths and tubers. It is well known that pure white tubers have occasionally been taken from roots of red Potatoes, and *vice versa*, and that these "accidentals" retain their character. A striking example of sportiveness may be seen in the Reading collection, for already a white Maglia has been produced. The tubers of *S. Maglia* appear to vary somewhat in colour. Some of those sent by Lord Cathcart to Mr. Sutton were much paler than others, and the stock was thus divided into two sections; but the colours were not fixed, as the produce of both lots was practically identical; yet during the past summer one of the stems of a plant was light in colour (the prevailing colour of the stems is reddish). This light stem was taken off as a cutting, and the plant so established has produced white tubers, having all the appearance of tubers raised from a cultivated variety, and as such according to botanists a descendant of *S. tuberosum*. However this may be, there is every probability that next year varieties the produce of *S. Maglia* will be grown identical in character with Potatoes in general cultivation.

Humboldt, in his essay on New Spain, believes the plant described by Molina under the name of Maglia is the original stock of this useful vegetable. In De Bry's collection of voyages Heriot's report of the country visited by Sir Walter Raleigh is included, and the Potato is referred to as having tubers as large as Walnuts, some much larger. They grow in "damp places," and are good for food either boiled

or roasted. This is descriptive of *S. Maglia*, and Heriot was in the expedition of Raleigh when tubers were collected and brought to Ireland.

It has been observed that the figures of Clusius and Gerard (1633) are identical, the former work being published in 1601. Twenty years afterwards Bauhin's "*Prodromus*" appeared, with an original figure of a Potato plant. This perhaps still more closely resembles *S. Maglia*, and has scarcely anything in common with the figure of *S. tuberosum* as prepared at Kew and published in the Linnean Society's Journal. It is true there are a few incipient leaflets between those of full size, but these are not nearly so marked as in Baker's figure; while the whole character of the plant, and especially the large cordate terminal leaflet, is almost identical with Baker's figure of *S. Maglia*. This broad terminal leaflet is seen in late strong-growing varieties of English Potatoes, but is less prominent in the early Ash-leaved varieties, and these, too, have as a rule a greater number of leaflets, and of more uniform size than is common with the stronger and later section.

Mr. Baker's figure of *S. tuberosum* has a general resemblance to the Early Ashleaf type, and that species may have been the progenitor of this race, which, from a cultivator's view at any rate, is distinct from the other. This is a question for the consideration of botanists, and it may be mentioned that Dr. Hogg has failed in his attempts to cross *S. Maglia* with an Ashleaf; but Mr. Sutton has succeeded in crossing it with another variety. The question is, Is the Ashleaf a true descendant of *S. tuberosum*, and with little or no mixture of *Maglia* in its constitution?

Mr. Sutton grew thirty-six plants of the wild *S. tuberosum* from seed sent him by Mr. Thiselton Dyer of Kew sown last April, and treated exactly in the same manner as the hybrid seedlings. The total result from these thirty-six plants was sixty-eight tubers, weighing in all $1\frac{1}{2}$ oz., which bears but a poor comparison with some of the single hybrid plants. He also grew the wild *S. tuberosum* from a tuber obtained from the College of Pharmacy at Philadelphia, which was discovered by Professor Lemmon on the Xuachuca Mountains at an elevation of 9000 feet. The result of this plant was several small and apparently worthless tubers. In neither case would the plants of *S. tuberosum* cross with any of the cultivated forms of the Potato that were tried at Reading.

There is no increase in size in the case of the Philadelphia tubers, and those raised from seed are now about the size of the one tuber received from Philadelphia last winter.

Many attempts were made to cross *S. tuberosum* with the cultivated Potato, but in no single case was any result obtained. On the other hand it was found comparatively easy to cross *S. tuberosum* with *S. dulcamara* (Wild Nightshade) and *S. nigrum*.

The true Ashleaf Potato seldom flowers, but if flowers of the smallest form, called on the Continent the Marjolin, can be produced as Knight produced them by preventing the development of tubers, and pollen obtained, it will be worth while trying its effect on *S. tuberosum*.

Under any circumstances, Mr. Arthur W. Sutton is to be warmly congratulated on what he has so far accomplished in the important work with which he was entrusted, and we look forward with interest to the result of the experiments that will be conducted next year, other important crosses having been effected with *S. Maglia*.

THE COMING RACE OF ROSES.

If "A. C." will refer to page 82 I think he will hardly consider the report of Etendard de Jeanne d'Arc a very favourable one, and in fact this Rose seems likely to turn out "quality No. 2," for the whole appearance of the plant indicates a recurrence to the Bourbon side of the family, and quality is not the Bourbon's strong point. Deducing a hybrid's origin from its outward characteristics or habit may perhaps be objected to as only presumptive, and therefore inadmissible; but as there are so few records of the origin of Roses (and even those preserved generally give only the seed parent), until the hybridisation of these plants be much more

exactly effected and noted, no other method of classifying the bulk of the florists' varieties exists. That the origin of a hybrid may be fairly accurately deduced from the evidence of its exterior is indicated by cases where the exact cross has been recorded. Moreover, it is well known that seedlings raised from a hybrid frequently show a tendency to revert to the form of one of that hybrid's parents. Now it has long been held that Gloire de Dijon originated from the crossing of some Tea-scented Rose by a Bourbon variety. True, there was no yellow Bourbon that could have assisted in the production, but then Gloire de Dijon is only a yellow Rose by courtesy on a north aspect, and the opaque colour (as in Bourbon Queen) that seemed to overlie the yellow in the petals, the flat expanded flowers with the stamens all hidden by the doubled-over petals (as in Souvenir de la Malmaison), and the broad leathery leaves, were deemed sufficiently conclusive evidence. Myriads of seedlings have been raised from Gloire de Dijon, many inclining more to the Tea-scented type, as Belle Lyonnaise, &c., until now comes the white Etendard de Jeanne d'Arc, which at a little distance looks like the ghost of a Souvenir de la Malmaison. This seedling therefore affords an additional indication by reverting to a Bourbon type that the supposition, founded on its external characteristics, of Gloire de Dijon having been a hybrid between a Tea and a Bourbon was well grounded, and this may serve as an argument in favour of reasonable deductions of a similar kind in other cases.

To cite two other well-known varieties from the list of Hybrid Perpetuals in the National Rose Society's illustrated catalogue. La France is a Rose which, with its smooth dark glossy foliage, extreme freedom of flowering, and manner of growth, together with the delicate form and texture of its slightly pendulous blooms, at once recalls the general habit of the Tea-scented varieties, and we have M. Guillot's word for it that its seed parent was a Tea. While M. Lacharme's statement that Captain Christy resulted from a cross between Victor Verdier and Safrano may be readily credited from the outward appearance of this beautiful and worthily named Hybrid Tea—a term, by the way, that seems greatly to exercise some people's minds; for at a certain Rose show this year a medal for the best Hybrid Perpetual in the exhibition was awarded to a bloom of Lady Mary Fitzwilliam, a Rose in many ways resembling Captain Christy, and especially so in being of similar origin, for its raiser (Mr. Bennett) states that it resulted from a cross between Victor Verdier and Devoniensis. The judgment, however, was subsequently reversed, on the alleged ground that Lady Mary Fitzwilliam was not a Hybrid Perpetual. The question immediately arose, What is a Hybrid Perpetual? Is it a hybrid that flowers a second time in autumn? Clearly not, if Lady Mary be not one, for the second flowering of that Rose is as free as its first. Is it a hybrid in which there is no Tea blood? Certainly not; for in the National Rose Society's catalogue the best known Hybrid Teas, La France and Captain Christy, are classed as Hybrid Perpetuals, as they always have been since the date of their introduction. It would seem, therefore, that Lady Mary Fitzwilliam has been held to be not a Hybrid Perpetual, either because it flowers freely again during the autumn, or else because it is of similar race and origin to several other well-known Hybrid Perpetuals. Canon Hole might apparently have added another abstruse appellation to the amusing list on page 183 of his "*Book about Roses*." The National Rose Society did their best to uphold the cause of common sense by awarding the silver medal for the best Hybrid Perpetual in their Northern Show at Manchester to a bloom of Lady Mary Fitzwilliam, and no doubt the required definition will soon be forthcoming to remove the possibility of future heartburnings over such confusion as to the meaning of terms.

Now if the parents of a hybrid may be fairly accurately judged from its outward appearance, so it may also be surmised, though not with nearly so much certainty, what would be the result of any given cross. We already have varieties with perfect flowers in almost every shade of colour, and the demand that raisers in future will have to supply before Rose-growing will become as universal as it ought to be will be for varieties of equal beauty and much more vigorous habit of growth and more certain perpetuity of flowering—a quality which in a Rose of mixed race may be considered for the moment while "awaiting further instructions" to constitute a Hybrid Perpetual. Thus Louis Van Houtte and Marie Baumann, two perfect Roses when doing well, are in many localities but poor growers, and often die out after two or three years. Why should not some vigorous autumnals be fertilised by these more beautiful Roses, with a view to obtaining seedlings that shall unite in their strength and beauty the best points of their parents? It is with this view that rosarians should not be in haste to condemn such varieties as Madame Isaac Pereire to whom, even though expressions of contempt may sometimes cause her to glare green-eyed with jealousy upon her more beautiful sisters, a rough

exterior will be readily forgiven if she shall become a mother of giant heroes. In the same way Gloire Lyonnaise must not be at once discarded because it is not perfectly full, for it is distinct and very vigorous, and the thin Roses are the best seed-bearers. So let it be fertilised with all sorts of other varieties, and see if it will not give us seedlings worthy of the raiser of La France. For it cannot be expected that a race of faultless Roses shall spring up all of a sudden, and for a long time advantage must be taken of any valuable characteristic that any variety may possess. Thus at first there will be vigorous growers with fine flowers, but, subject to mildew, or not autumnal, good autumnals resisting mildew, but with flowers perhaps dull in colour or faulty in shape, and so on. There are already at any rate two Roses, George Baker and Mrs. George Dickson, that seem to have a wonderful power of resisting mildew, and additional encouragement to persevere in attempting to perpetuate this characteristic should be found in the success which has attended the efforts to raise seedling Potatoes capable of resisting disease. In the meantime rosarians must be content to wear their Roses "with a difference," and should be alive to the necessity of opposing a tendency to consider only the floral distinction without regard to main device displayed when criticising a cadet of the Rose family.

It was hoped that a beginning in really vigorous Hybrid Perpetuals had been made by Madame Gabriel Luizet; but unfortunately that vigorous and free-flowering variety seems to have been obtained by means of some summer Rose, so that it is a victim to mildew, and is very chary of its flowers in autumn. Lady of the Lake seems to have the vigour, but not the perpetual blooming. Perhaps Her Majesty will prove the paragon of all the virtues that her title implies.

But evidently these are the points to strive for in future in raising Roses—vigour of growth, perpetual bloom, and freedom from mildew; and let it be hoped that the lull in the rush of novelties alluded to by "A. C." may be owing to the growing conviction in the minds of raisers of the necessity of these qualities. It is quite possible that there may be shades of colour between which yet another may stand and be held distinct, but if there be not vigour no progress is being made. A perfect bloom of Mrs. Laxton, Constantine Tretiakoff, or Olliver Delhomme is as lovely as may be; but there will be deaths among such varieties every year, and it is this kind of Rose with no constitution that disheartens would-be growers who have not the time to give to their gardens which more fortunate enthusiasts manage to afford. And therefore it is important, without carping too critically at the imperfections of really vigorous Perpetuals of strong constitution, but noting their good qualities, to try and obtain from them such varieties that those who most need them, working hard elsewhere than in gardens, may in their brief leisure be refreshed during summer by first-rate Roses, which shall be there again to welcome them on their return home in September after their August holiday.—T. W. G.

CANKER IN FRUIT TREES.

I do not intend to trouble your readers with any lengthy remarks again on this subject. I happen to have an opportunity to send by a friend a young specimen tree, completely refuting the root theory of "Lathyrus's" cause of canker, page 247. The roots of this tree have never been 6 inches below the surface or in the subsoil. "Lathyrus's" treatment is excellent I have no doubt, but if I cure canker without disturbing a root by very careful pruning—i.e., cutting out all the cankered wood, and so getting rid of that containing the insects as I advised, I contend the cause is easily detected above ground.

I am well acquainted with half a dozen kinds of insects occupying cankered places, although I am unable to name all, but perhaps our friend "Entomologist" can give the name of the tiny fellows which are invariably found in every instance. I admit I assume these to be the cause of canker, for the good reason that they are always underneath the dying bark, and consequently cannot be seen eating it as we see a horse or cow grazing in the field. I should be sorry to charge even an insect wrongly, but why are we not to believe them to be the cause if always found there? We charge aphides, scale, mealy bug, thrips, and others with mischief without actually seeing them eat our trees and plants. If I get rid of canker by getting rid of the insects, I want no better proof of them being the cause and not the effect of canker. An hour with the microscope is of more use in such a case than any amount of writing.—J. HIAM.

[Some examples of cankered wood sent by Mr. Hiam have been examined by "Entomologist," who remarks on them as follows:—"The portion of Apple wood sent contained only a few perfect mites, but many exuviae and portions of bodies, suggesting that this species had been preyed upon by some parasite, presumably of the same tribe, but of another family. To ascertain positively the name of this insect would require an examination of various specimens by high microscopic power, and the group is acknowledged by continental observers, who know much more about the Acari than we Britishers do, to be one of unusual difficulty; the names are hard to determine, and their habits are obscure. I

feel, however, that I can hardly be in error when I pronounce it to be one of the beetle mites of the genus *Hoplophora*, and probably the victim frequently of a parasite nearly as large as itself, a Tyroglyphus, belonging to the cheesemite division of the Acari. How perplexing these creatures are is shown by the circumstance that what some naturalists regard as the adult stage of some *Hoplophora* has been considered by others to be a parasite which has lived in the skin of the mite which has been the vegetable feeder. The solution of these difficulties would not materially affect the question whether the insect is the cause or the result of the canker. Claparède of Geneva, who studied particularly one species of *Hoplophora* that occurs on the Fir, where it makes burrows of some length, remarks that it is found upon wood that is moist and decaying. A species was detected by Mr. A. Murray upon the roots of the Vine, but this appeared only to be present where phylloxera had brought the plant into an unhealthy condition. Such facts rather favour the theory that these mites make their attack on Apple wood when it has passed into a sickly condition."

Referring to the young tree sent by Mr. Hiam, we have to say that though the roots are quite clean, the union of the scion with the stock is so faulty, and the ligatures that had been employed were left in position so long, that the tissue was ruptured and the sap vessels contracted and obstructed to such an extent that the tree could not possibly flourish, no matter how good the soil might be in which it was planted.]

NOTES AT UPPER HOLLOWAY.

ORCHIDS.

MR. B. S. WILLIAMS' nursery at Upper Holloway has become so celebrated for its wonderful collection of Orchids, that a visitor naturally proceeds first to the houses devoted to them, and though October is not a month in which to expect a great display, it is surprising how many beautiful and rare plants are flowering there now. They are mostly scattered through the collection, but were they gathered into one house quite a gay little exhibition would be formed. In several of the houses there are banks of attractive plants facing the doors, and comprising the following—*Zygopetalum Gautieri*, a purple-flowered form, much in the way of *Z. maxillare*. *Vanda cerulea* is represented by several plants of good varieties, one bearing a spike of nine flowers. *Cattleya Gaskelliana* is also handsome, bearing flowers freely, four or more in a spike, the sepals and petals blush-tinted, the lip rich crimson with an orange throat. This is notable for the long period the flowers remain in good condition, those we saw having been expanded for three weeks, and they still looked quite fresh. *Cattleya superba* is represented by a grandly coloured variety; the bright yellow *Oncidium varicosum*, the graceful pale violet and white *Ionopsis paniculata*, and the old well-named *Odonoglossum grande* add their charms to the groups. Late-imported plants of *Oncidium concolor* are flowering now, this being a habit which Mr. Williams has repeatedly observed in this useful Orchid. *Oncidium pretextum* has several panicles of brown flowers. *Sophranitis grandiflora* has some large and brightly coloured flowers. *Leptotes bicolor* is charming suspended in small pots, its narrow white sepals and petals contrasting pleasingly with the crimson-purple lip. *Oncidium tigrinum* has numerous flowers. *Laelia autumnalis atro-rubens* is an exceptionally richly coloured variety, the flowers being flushed with deep crimson.

The lovely little *Pleiones maculata* and *lagenaria* are in capital condition, the former with white sepals and petals and crimson-spotted lip, the latter with pale purple sepals and petals, and a white lip with crimson streaks and tip. A few potfuls of these, with the larger *P. Wallichiana*, are particularly pretty at this time of year. They are now assigned to the genus *Cœlogyne*, but it will be a long time, for the much better sounding garden name will become obsolete. They have only one defect—viz., flowering without foliage, and to remedy this a few young Ferns are annually planted in the pots or pans with them. Another useful plant that is destined to become a great favourite is *Dendrobium Vealei*, of which Mr. Williams has an uncommonly fine specimen. The flowers are pure white with broad rounded petals, and are produced with great freedom, rendering them well adapted for cutting, and as white Orchids are scarce they will be much appreciated for that purpose. The plant in question has four racemes each with ten to fourteen flowers, that with the last named number being one of the finest we have seen. *Cypripediums* are represented by *C. punctatum violaceum*, one of the best of the insigne type; *C. Sedeni* with dozens of its rosy flowers; *C. Spicerianum*, now an established favourite; and *C. Harrisonianum*. *Cattleya Regnellii* is showing flower. *C. Harrisoni violacea*, having crimson sepals and petals, a white lip, and a crimson throat, is handsome; the curious *Cœlogyne Massangeana*, with white, buff, and brown flowers; the famed Dove Orchid, *Peristeria elata*, the old *Oncidium Lanceanum*, and several fine *Vandas* of tricolor insignis, Warner, and Dalkeith varieties are all both beautiful and interesting. The grand plants of *Cattleyas* are in the best of health, and showing sheaths as abundantly as could be wished.

In some other houses there are large stocks of choice Orchids, such as *Dendrobium superbiens*, which is remarkably well grown at Upper Holloway, though it is reputed difficult to obtain in satisfactory condition. None of this difficulty appears to be experienced at the establishment named, for the plants grow and flower splendidly. The temperature in winter falls as low as 57° occasionally, but the chief point in its success is considered to be providing a light position fully exposed to the sun to ripen the growth. It is a handsome Orchid, and worthy of all the attention needed, as the flowers last for an astonishing time. In the same house *Vanda teres* and *V. Hookeri* are grown with similar success, and look most vigorously healthy. *Dendrobium Ainsworthi*, *D. Bensoniae*,

and *D. Waltoni*, a variety of the crassinode style, are growing most strongly, while large numbers of *Calanthe Williamsi* have made wonderful pseudo-bulbs in 60-size pots. Some of the pseudo-bulbs of this charming addition to the genus are 9 inches high and 3 inches in diameter. In the cool houses is an extensive stock of *Masdevallias*, *Odontoglossum*, the cool *Oncidiums*, and other plants. Varieties of *Odontoglossum* *Alexandrae*, *Pescatorei*, *Ruckerianum*, *Andersonianum*, and *nævium* are flowering now, several being of great beauty. There is a surprising stock of *Epidendrum vitellinum majus*, at least 500 plants being suspended in one house, and there is about the same number of *Barkerias*.

MISCELLANEOUS.

But there is much besides Orchids in Mr. B. S. Williams' houses; much more, indeed, than can be enumerated now. A few jottings may, however,

basket Fern, *Adiantum dolabriforme* (fig. 58), which might well be added to any collection of Ferns. It is of similar habit to *A. lunulatum*, but instead of being deciduous, as that species is, it is evergreen. The pinnules are also rounder, and the fronds bear at their tips young plants like several other species of this section. The character of the plant is faithfully shown in the woodcut (furnished by Mr. B. S. Williams).

The *Nepenthes* constitute a beautiful display in the long house devoted to them, there being some hundreds of pitchers of fine proportions and variously coloured, all the best forms being represented, and several promising novelties are also coming forward. In other houses there are hosts of *Ixoras*, *Dipladenias*—which have long been a feature in this nursery—*Tabernaemontanas*, and *Gardenias*. Then in cooler houses are magnificent specimen *Camellias*, *Rhododendrons*, *Ericas*, and miscellaneous hardwooded plants innumerable. The collection of Heaths is

Fig. 58.—*ADIANTUM DOLABRIFORME*.

be given concerning the most prominent. Of general stove plants the stock is a very large one, comprising all the best of both the flowering and foliage types. The collection of Ferns is particularly rich, all the most ornamental genera being well represented by their best species, while those gems of the Fern world, the Filmy Ferns, *Todeas*, *Trichomanes*, and *Hymenophyllums*, are especially strong in numbers, including many rare and choice species. Of *Gleichenias* there are some fine specimens, which, for clean healthy growth could scarcely be surpassed. *Adiantums* are also largely and well grown, all the old favourites and the new introductions being included. Amongst the latter is a very graceful

an excellent one, the plants being just of a suitable size and in fitting condition for growing on into specimens for exhibition. It is regrettable that so many handsome *Ericas* have lost favour in gardens, but it seems very probable that they will regain the popularity they so well deserve.

EFFECTS OF EARLY PRUNING ON VINES.

SEVERAL correspondents have touched upon this subject, and the balance of opinion at present rather favours the idea that moderately severe shortening of the laterals is beneficial rather than injurious. Mr

Gilchrist, however, rather misinterprets the sense of my remarks, especially with regard to cutting back the laterals that have perfected exhibition bunches. What I plainly stated on page 274 was that those early and most severely pruned laterals do not, according to my experience, produce nearly such fine bunches the following season, but I did not express the opinion or imply that the remaining spurs would be also weakened. Then if this happens in the case of these particular spurs it is quite possible for much injury to be done by a wholesale premature shortening back. The instance I gave of such an injury apparently thus accruing may perhaps add but little to my theory, as overcropping, as Mr. Gilchrist suggests on page 321, may have been the sole cause. There is not the slightest doubt, I should say, about the wisdom of the judicious shortening of the laterals, and my object in referring at length to the by no means new practice was both to elicit opinions from others more experienced in the matter than myself, and also to warn others from a reckless abuse of the system. We cut this season about eighteen bunches of Black Hamburg for exhibition purposes, and in some cases we were almost unavoidably obliged to cut away the laterals to within 3 or 4 inches of the rods, and this from experience I can safely assert will result in the formation of smaller bunches on those particular spurs. They will, however, be marked and the results duly noted, and next season I hope to hear of a good many growers' experience in the same direction.

Now that so many of us have caught the "Chrysanthemum fever" early pruning will be extensively resorted to "in order that they may let in more light to the Chrysanthemums that have to be put inside;" but let us hope this "letting in of light" may not be overdone, the "Mums" being unduly favoured at the expense of the Vines. It must be remembered that it is in the autumn when the latter recoup their nearly exhausted energies, and it is at this time that the root-action should be particularly brisk, and if we remove the foliage at a wholesale rate we greatly diminish both the storing up of food and the formation of fibre. On the other hand, if we gradually shorten the laterals so as to leave about four or five fully developed leaves, these are sufficient to maintain a reciprocal action with the roots, and will store up the bulk of the food where it is most desirable—viz., at the base of the laterals. This judicious shortening also favours thorough ripening, and lets a certain amount of light into the house, but certainly not enough for a bank of Chrysanthemums, unless the Vines were either early or more thinly disposed than is usually the case.

In reply to "J. L. B." concerning the advisability of an early removal of the lower sub-laterals, I can only remark that in this as in many other cases very much depends upon circumstances. Our main rods are 42 inches apart, and we can therefore lay in the laterals to a good length, which we do, and closely rub out all the sub-laterals. All we aim to secure, whether rightly or wrongly, is plenty of fine foliage without unduly crowding it, and I fail to see what good the retention of the sub-laterals would do. Where the rods are only 2 feet or rather more apart, the laterals must be necessarily correspondingly short, and in this case the removal of the sub-laterals might very probably result in the premature bursting of many of the buds. Besides, if it is an undoubted fact that the leaves all contribute to the stock of stored-up sap, and if we cannot have them in one place we must preserve more in another.—W. IGGULDEN.

THOUGHTS ON CURRENT TOPICS.

I SHALL always be glad if any correspondent will advance a few ideas for me to think about. If they are good I will endeavour to profit by them; if of the other sort try to make the best of them. Our old critic "Non-Believer" has been tempted from his obscurity once more. Faithful to his *nom de plume* he only writes to oppose. His unbelief appears to be of a genuinely chronic kind, and the more attention he bestows on my humble efforts the greater the honour—to myself.

I DARE SAY your acute correspondent thinks he has fixed me on a crucial point—the degradation of exhibiting as exemplified in promoters of shows having as a main object the attraction of visitors and consequently good financial receipts in the form of gate money. But I shall survive the soft impeachment (no emphasis on the "soft" please). If the proceeds of horticultural exhibitions were appropriated by the managers, then their action would be "low" indeed and absolutely indefensible; but as it is not so, as numbers of them work zealously and gratuitously, and are out of pocket into the bargain, I am prepared to say their procedure is commendable.

LET us think the matter over calmly before passing a verdict of condemnation on the managers of exhibitions who strive to do their duty. In the first place "where does the money go" that is received for admission? First to the necessary administration, then in the form of prizes to successful competitors. If gardeners were content to show for smaller prizes, and esteem the honour of winning a reward in itself, plus costs incurred, persons who are responsible for the success of societies would be delighted, as they would be relieved of a great cause of anxiety in respect of the finances.

THE fact of the case is this—nine-tenths of those who make themselves responsible for the success of exhibitions of garden products are imbued with a deep love of gardening, and are animated with an earnest desire to induce others to love it too. They are willing to work almost night and day in what they believe, and I believe, and what I think the majority of the readers of these notes believe, is a worthy object, and the efforts they make to obtain the necessary means for achieving their end is, I respectfully submit, in every way creditable and not degrading.

THE greater the number of visitors who attend shows the better in every way—the better for the visitors, who not only derive pleasure from inspecting the products of skilled cultivators, but are animated with a desire to become cultivators too, and thus a wider and deeper interest is taken in the art of horticulture. The more visitors the more money; the more money the larger the schedules and better the prizes; the better the prizes the greater the competition; and the greater the competition the better the products must be to secure honours. Thus it seems to me that superior culture is the most encouraged by those societies that are the most financially successful. When gardeners are willing to exhibit as well for small prizes as they do for large, and when the affluent will defray administrative expenses, it will be soon enough to denounce "gate money;" but such a millennium is not yet arrived, and judging by past episodes is not approaching. Instead of gardeners magnanimously ignoring money, I could tell of more than one who in their view had not received their "pound of flesh," threatened managers of shows with actions, and of disputed cases being settled under protest to avoid proceedings that would not have tended to the promotion of horticulture. I doubt very much if even "Non Believer" will non-believe that.

I THOUGHT it a little curious that, with the object of drawing up a "protest," the weight of the names of such once-eminent personages and old-time horticulturists as Mr. Knight, Mr. Wedgwood, and Sir Joseph Banks should be invoked. By the association of such personages with himself your correspondent may have given a literary finish to his production; but however eminent the quartet the trio at least knew little more about the management of horticultural shows of the present period than did old Mother Hubbard, and far greater authorities on the subject are the secretaries of Horticultural Societies now established, who know very well that without good financial support they are powerless to "encourage horticulture" in a satisfactory manner. They therefore exert themselves to obtain that which is a necessity of the very existence of societies, and those which are the most flourishing reward merit the best and advance the art and industry of horticulture the most effectually.

AFTER this defence of a body of men who are accused of being engaged in a "low" calling, "Non-Believer" may have some sort of excuse for rivetting me to a creed. He had none whatever before, and the critic who cannot discriminate between a narration of circumstances—the acts of others, and the formulation of a creed by the narrator, is either wanting in perception or is animated by an object of not a particularly elevating character. The credit of the suggestion, that I do not care whether fruit and flowers are well cultivated or not, rests with him who advanced it, and I have an impression that he will not have a rush of followers who will covet a share of the "honour." I have the happiness of entertaining a better opinion of others who may differ from me on sundry points, and envy not the disposition of any person who derives pleasure in searching for and attributing to others motives of professional disloyalty.

AS to the question of exhibiting summer Grapes only at late summer and autumn shows, I have as yet seen nothing to induce me to alter my expressed opinion, and if "Non-Believer" is in a position to say that he has never exhibited Grapes that were not ripe and in the best condition for table, and on that account received no prize for them, I shall attach more weight to his remarks than I am able to do at present. As I expect no declaration from others I am unwilling to make myself, I at once say that, whatever disadvantages I happen to labour under, I am at least not a disappointed exhibitor, and am absolutely without prejudice in discussing this matter.

NOR do I think all the writing that is indulged in will result in any satisfactory Grape competition in the winter on the lines that have been suggested. It will do good if it impresses on managers of shows the importance and even the necessity of greater care in the appointment of Judges; and if, as was previously mentioned, a line of guidance were appended to certain classes in the schedules, neither exhibitors nor Judges would have any excuse for any mis-

takes they might make. At the same time there need be no exclusion of varieties, and the collections staged would be as large, varied, and interesting as ever. The prizes offered for Grapes at Chrysanthemum shows are such as only local exhibitors are expected to compete for, and I am not at all surprised that the directors of the National Chrysanthemum Society should decline to vote such a large sum as would be needed for insuring a great display of late Grapes in January. And, besides, however well represented late Grapes might be at a show in midwinter, that would have no bearing on the incongruous association of varieties in summer and autumn and of size handicapping quality then, which is the real grievance with many. If there is to be a late Grape gathering let it be under the auspices of the Royal Horticultural Society at South Kensington, not a mere offshoot of a Chrysanthemum show at the tail end of the season.

I HAVE been requested to express an opinion on the subject of what may be termed half-pruning Vines in summer and autumn—that is, shortening the laterals to say half their length some time before the leaves fall. Mr. Iggulden, who seems to be a pioneer in introducing subjects for discussion, has doubts as to the soundness of that practice. Other correspondents have not. The differences, I think, may be resolved into a question of time. If a few bunches are cut very early with a good length of lateral, and before the foliage has deposited any material amount of nutrient matter in the stems, and at the same time the other laterals are permitted their full length and even to extend, it is conceivable that the shortened laterals would be weakened; but if the foliage is quite matured, or, in other words, if the laterals are shortened after the fruit is fully ripe (say in September instead of July), the case is entirely altered. I am of opinion, and it is founded on observation and experiment, that if as soon as the foliage shows signs of change, no harm, but rather good, is done to healthy Vines by a general shortening of the laterals, and it is certainly good for plants that have often to be placed in houses in the autumn long before the leaves fall from the Vines on the roof. If the crop of Grapes were cut, and it was desired to fill the vinery with Chrysanthemums, I should not hesitate a moment in shortening the laterals, provided, and this is important, at least four good leaves could be left on the portions remaining. That is my little contribution on this interesting subject, and it will depend on circumstances as to whether I refer to it again.

POTATOES have been to the fore again, as is natural at this period of the year. On this subject "A Plain Gardener" has made some practical suggestions. It is certainly important to know within a week or two when varieties are ready for lifting, and it seems clear that we are no longer indebted to Americans for new varieties. I suspect some of those regarded by your correspondent as "new" are more extensively cultivated than he imagines. Reading Hero, Reading Russet, Beauty of Hebron, and Schoolmaster I have seen grown in fields for market. Perhaps, as your correspondent is of such a utilitarian turn of mind, he will favour us with a short list of varieties that he has found reliable for maintaining a regular supply of superior produce—a little matter which in his zeal for "plain" information he appears to have overlooked.

ANOTHER bone of contention is thrown by "Euphrasia" for critics to pick at, and I may as well have a nibble before it gets stale. The "bone" is a soft one—Cucumbers. It is true they are often curiously judged. Sometimes it would appear as if the prizes were given for length of fruit, sometimes for weight, and occasionally for quality. It is not, I think, customary to award prizes to "varieties." The best judges give them to the best fruits staged, and they could not well do anything else; but at the same time quality is the first consideration, and fresh, uniform, short necked and nosed examples, a foot long, with the flowers adherent, are placed before coarser specimens of twice that length by competent judges.

I HAD no idea until I read the article on page 323 that Trinity College Botanic Gardens, Dublin, were so extensive and richly furnished as they appear to be. Your correspondent, according to his remarks at the bottom of the page, appeared to be somewhat bewildered as to know where to begin, and intimated that seven numbers of the Journal would be required for him to say all he desired. I thought, Now for something exhaustive and elaborate, but on turning over the page the great work was condensed into ten lines. Perhaps, after all, it is better to describe Mr. Burbidge's work in instalments. Many a good hint has been sent over from Ireland, and I always read Mr. Murphy's notes with pleasure.—A THINKER

THE Committee of the GARDENERS' ROYAL BENEVOLENT INSTITUTION will meet early in November to consider the proposed additions to the pension list. Baron Schröder, The Dell, Egham, has been elected Vice-President in place of the late Edmund Wilder, Esq.

— MESSRS. HODDER & STOUGHTON, 27, Paternoster Row, have issued a little volume on BIBLE FLOWERS AND FLOWER LORE, which comprises a series of papers that originally appeared in the *Jewish World*. It includes 151 pages, is neatly printed and bound, and gives a full account of the plants mentioned in the Scriptures. It is somewhat in the same style as Mr. J. Smith's work on this subject, but is not illustrated.

— RELATIVE to the GRAPE JOHN DOWNIE, a correspondent writes:—"I think both Mr. Downie and Mr. Dunn ought to take some notice of Mr. McIndoe's letter on page 310. It is said in Scotland that the raiser of John Downie had a black berry come in a bunch of Muscat of Alexandria, and the two seeds in this berry produced the two John Downies that are to be seen at Dalkeith. It will be interesting to know something more of this phenomenon."

— THE well-known plant collector, Mr. BENEDICT ROEHL, recently died in Austria at the age of sixty-two. Mr. Roehl had travelled widely in America, especially in the central and southern districts, and collected enormous numbers of plants; indeed, it is said that in one journey he forwarded 8 tons of Orchids to London.

— MANY florists will learn with regret that Mr. SAMUEL BROWN, Crompton Road, Handsworth, Birmingham, died on the 16th inst. at the age of seventy-one years. For more than forty years he has been a successful cultivator of the Carnation and Picotee, and has gained a much more than local reputation.

— WE learn that the Geneva Natural History Society offers a prize of 500 francs for the best MONOGRAPH OF A GENUS OR FAMILY OF PLANTS. It can be written in Latin, French, German, English, or Italian, and should be sent to M. le President de la Société de Physique Naturelle de Genève, à l'Athénée, Genève, Switzerland.

— A CORRESPONDENT recommends the following plan of PRESERVING DAHLIA TUBERS, which he says is practised by M. Viards-Clirot, vigneron et forestiere de l'Aube. He pulls up the roots about the 15th of October, and then leaves them to dry in the sun for several days. He then takes barrels with one end off, places hay at the bottom and round the sides, and fills up the central space with the clusters of the tubers, which are placed one above the other, covers with hay, so that the barrels should be well filled, replaces the end, and stands them in a dry place, to be opened again about the end of March.

— A WORK ON FRUITS AND FRUIT TREES, HOME AND FOREIGN, by Mr. Leo H. Grindon, has just been issued by Messrs. Palmer and Howe, Manchester, which contains a variety of interesting historical particulars and folk lore relating to the principal cultivated fruits. We just notice the issue of this book now, but shall have occasion to refer to it at greater length another time.

— GARDENING APPOINTMENTS.—We are informed that Mr. Wardle is resigning charge of Mrs. Joicey's garden, Newton Hall, Stockfield-on-Tyne, to commence business for himself as landscape gardener and nurseryman; he is to be succeeded by Mr. Dundas Macrae, late head-gardener to Viscount Massereene and Ferrard, Antrim Castle, County Antrim, Ireland.

— MR. F. W. BURBIDGE, Trinity College Botanic Gardens, Dublin, sends us a choice collection of SEEDLING CROWN ANEMONES from St. Brigid's garden on the Hill of Howth, near Dublin, and remarks that "They are now (October) not so fine, of course, as they will be next spring (March), but still they are bright and beautiful at this dull season of the year. These flowers are the produce of seed sown in March last, 1885. They are extremely fine blooms for the time of year, large, full, and varied in colour, the tints being very rich and bright."

— THE EXETER APPLE AND PEAR SHOW that was held on the

22nd inst., appears to have been a great success. There were ninety-five exhibitors as compared with eighty last year; the number of classes fifty-three, as against thirty-eight; and the number of entries 734, against 522. In the competing classes 1690 dishes of Apples were arranged, representing 10,000 fruits; and 338 dishes of Pears, representing 1680. The entries in Tomatoes and other fruit brought up the total to 12,190. Besides these there were numerous exhibits not for competition. Among them the magnificent fruits exhibited by Messrs. Lucombe, Pince & Co. were conspicuous for their excellence. They had on view 336 dishes. The firm's collection of Pears was a splendid assortment of some of the choicest kinds. Messrs. Veitch & Son had an exquisite assortment of 130 dishes well displayed; and other exhibitors, not for competition, were Mr. Stokes, St. Thomas, who sent thirty boxes of French Pears; Mr. Moore, Torquay, whose collection of Tomatoes was very much admired; and Mr. Bunyard of Maidstone.

— AT the YEOVIL CHRYSANTHEMUM SHOW, which is to take place on November 17th in the Corn Exchange of that town, a silver cup, value £5, or cash if preferred, will be offered for twenty-four blooms, twelve Japanese, and the same number of incurved. Two of the National Society's silver medals and two certificates are also offered, as well as numerous prizes for table plants and fruits. The Hon. Sec. is Mr. C. Tite, Fair View, Yeovil.

— THE sixty-second ordinary meeting of the ESSEX FIELD CLUB will be held in the Loughton Public Hall, Loughton, Essex, on Saturday, October 31st, 1885, at half-past six o'clock. The following paper will be read:—"Mosses and their Allies, with special reference to those of Essex," by Professor Boulger, F.L.S., F.G.S., &c., Vice-President, E.F.C. In connection with Professor Boulger's paper, exhibits of herbaria and fresh specimens of Mosses (especially Essex forms) will be very welcome. The Secretary will be happy to pay carriage or other expenses incurred in sending up such collections to the head-quarters or to the meeting-room. Mr. W. Cole will exhibit on behalf of the Rev. O. W. Kenworthy, M.A., Vicar of Braintree, an interesting collection of stone implements, mainly found in the neighbourhood of Braintree and Bocking, Essex. The Hall will open at six o'clock for the convenience of exhibitors.

— THE Floral Committee of the NATIONAL CHRYSANTHEMUM SOCIETY held their second meeting of the year on Wednesday, October 28th, in the Westminster Aquarium. There was a small display of exhibits, although Dahlias and Tuberous Begonias were admitted besides Chrysanthemums. Several of the latter shown as new varieties were worthless as far as could be judged from the blooms sent, and the Committee will act wisely in restricting their certificates to really meritorious varieties. If they wish to add interest to the meetings they could invite growers to send blooms, and award cultural commendations for those deserving them. Mr. Wright of the Middle Temple; Mr. R. Owen Maidenhead; Mr. W. E. Boyce, Holloway; and Mr. Forbes, Roehampton, were the principal exhibitors, the first-named having some of the best blooms and varieties. Val d'Andorre, certificated at Kensington was also honoured here, and Mons. Freeman, an incurved scarcely in condition, was certificated. Mr. Wright also had good blooms of Souvenir d'Haarlem, a rosy-crimson Japanese. Mr. Forbes had M. Mousillac, Fleur de Bas, and M. Leon Brunel, the latter a curious quilled variety.

— MR. SYDNEY J. HICKSON, Batavia, contributes some notes to *Nature* on BOTANIC GARDENS IN JAVA, of which the two following paragraphs are interesting:—"On entering the gardens at Buitenzorg the stranger is at once struck with the wealth and luxuriance of the vegetation he sees, the great height of the trees whose trunks and branches are in many cases covered with heavy creepers, the dense copses of the different species of Bamboo, the eccentric-looking Screw Pines and the handsome Palm trees; but the scientific observer is also struck with the care that has been taken to arrange all these many varieties of tropical plant life in, as far as possible, their systematic order, and that each specimen has its scientific, and in many cases its Malay name also, clearly and distinctly printed on a little board by its side. Many families have probably more representatives in these gardens than in any in the world. The Sapotaceæ, for instance, so rarely seen in Europe, are here represented by a great variety of genera and species, and the Palmaceæ, the Rubiaceæ, the Burseraceæ, the Orchidaceæ, and other families have now a large number of rare and interesting representatives. The herbarium which is attached to the garden contains a large collection of dried plants and seeds collected together from the

many expeditions into the little or unknown parts of the Archipelago and from other sources."

— THE same writer continues—"The GARDENS AT TSI-BODAS are situated on the slopes of the Gedeh Mountains, at an altitude of 5000 feet, and here I found Dr. Treub at work in the comfortable little house which is attached to the gardens. From this spot a very wide range of vegetation may be studied, from the rich and varied vegetation of the plains to the interesting vegetation of the Gedeh and Pangeranso peaks, at an elevation of 10,000 feet. In the gardens themselves a very fine collection of Coniferæ from America, China, Australia, and other parts of the world has been got together, and spaces have been cleared for the growth of the various species of Eucalyptus, Cinchona, and other plants. Year by year the surrounding forest is being encroached upon by these gardens to make room for new importations. I saw, however, enough to convince me of the great importance of these gardens for the advancement of our botanical knowledge and the great opportunities they afford for research into all branches of the science. I need hardly say that the climate in this region is extremely pleasant and invigorating, and the neighbouring village of Sindanlaya is much resorted to by Europeans and others whose health has suffered on the coasts or low-lying districts of the Archipelago. At Buitenzorg the climate is by no means unpleasant or unhealthy, but as it lies a few thousand feet lower than Tsi-Bodas, it is naturally a good deal warmer; but I am assured that several Europeans have worked there for several years without feeling their health the least affected."

— MR. WALTER KRUSE thus describes his method of MAKING ZINC LABELS FOR FRUIT AND OTHER TREES WITH INK FOR WRITING ON THEM. Sheet zinc is cut of the desired shape, and a hole punched in it large enough for admitting a piece of No. 8 galvanised wire, the top of this is bent into S shape for securing the label, the lower part for inserting in the ground. This is the purport of what appears on one side of the paper, on the other the writer proceeds—"To make the ink for the label purchase some sulphate of copper, which is very cheap, at a chemist's, and make a saturated solution of it in water; that means that you cannot add too much copper, as the water will only dissolve a limited quantity, and the rest remains at the bottom of the bottle until more water be added. Use a quill pen. Shortly before being written on—as with all zinc labels—the surface of the label will probably require cleaning by being rubbed with some fine emery paper. The above-described label will last for years, does not force itself on the observation, especially as with some plants it can be placed almost out of sight among the foliage, and it can be made at home on a wet day when the men have not much to do. They can be used for a different name after being rubbed with emery paper. For tying without the galvanised stem to fruit trees I use strips of leather, as I consider wire dangerous, because if not seen to occasionally when the tree enlarges the wire injures it. With dwarf Rose trees tied labels are a nuisance, because every time the old wood is pruned away the label has to be shifted."

JUDGING AT FLOWER SHOWS.

MR. WILLIAMSON'S well-timed and able paper on "Judging at Flower Shows" I expected would ere this have received the attention of the critics, for the subject surely is of some interest. That some rules for the guidance of all concerned is fast becoming a necessity will, I think, be admitted by all practical men, whether from the standpoint of judge or of competitor. When Mr. Williamson tells us how his friend the nurseryman proceeded with the Roses judging—page 257—he shows the absurdity of our present system of judging cut flowers; and that plants, fruits, and vegetables are in many cases equally mismanaged is, I think, perfectly apparent. How all this may be remedied is a question of importance, and one calling for the consideration of our most experienced horticulturists. I consider Mr. Williamson's most able paper a step in the right direction. The plan he recommends seems practicable, and requires only to be more definitely put into form to pass the theoretical and find its place in actual practice. Convinced of this, and knowing that a thing well begun is more than half done, I beg to supplement Mr. Williamson's and submit the following.

First, Fruits and Vegetables.—Let a fixed national standard of maximum value be given to every kind of fruit and vegetable usually shown, and in accordance with such have test sheets printed and made up into books of convenient size, and which every horticultural society can procure for the use of its judges. I send two sketches, based on Mr. Williamson's model, to illustrate my meaning.

Second, Plants and cut flowers.—Here I must modify our system, for no fixed value can possibly be admitted, and the question may even arise, Are they then worth the trouble of a test sheet? This point I will not attempt to decide.

Now a word as to the standard value of the "mark." Mr. Williamson suggests four as the integral value. Here we differ for the first time. The decimal advance of our arithmetical notation suggests to me five or ten as a more convenient measure, and I should prefer to add the points to the marks rather than reduce the marks to the lower denomination. In conclusion, I may state that I by no means assume that the maximum values as rendered will be anything like just; they are simply added as they occur to me to complete the illustrations.

Since writing the above I have read "Thinker's" remarks on subject on page 313. I certainly concur with much that he says, but it must be remembered that good judges are not always at command, and in the nature of things the young and inexperienced must at some time make a beginning. No judges, we are aware, would think of troubling with points except in very close competition, and it is there that the value of a fixed standard would be acceptable.—W. A.

[It is not necessary to publish the blank tables, as they are practically the same as those represented on page 221 of our issue of September 10th, the only difference being that a column giving the maximum or standard number of points for each fruit or vegetable, as the case may be, the columns for marks and points awarded by the judges following the space for "remarks." In the "standard" column for fruit our correspondent places 10 marks for a Pine Apple, 9 for Grapes, 8 for a Melon, 7 for Peaches and Nectarines, 6 for Figs, 5 for Oranges and Apricots, 4 for Pears and Plums, 3 for Apples, 2 for Cherries and Strawberries, and 1 point each for Currants, Raspberries, and Gooseberries. In the "standard" column, as representing the relative merits of vegetables, the points are as follows:—Cucumbers and Tomatoes, 10 each; Vegetable Marrows, Celery, Leeks, and Onions, 9; Peas and Cauliflowers, 8; Asparagus, Seakale, Globe Artichokes, and Mushrooms, 7; French Beans, 6; Beet, Parsnips, and Carrots, 5; Cabbage, Turnips, Potatoes, and Brussels Sprouts, 4; Savoys, 3; Broad Beans, 2; Borecole, 1—a method of assessment which is open to discussion, as we suspect growers and exhibitors are not quite unanimous in their views on the subject. In the table for plant-judging space is provided for the names of all the specimens in the classes to which prizes are awarded, with accompanying columns for marks, points, and remarks.]

TREE MIGNONETTE.

THE earliest plants that have been prepared for this mode of growth have covered their trellises, and should be removed from the pits in which they have been grown to light airy positions safe from frost. The side stages of the Rose house is a capital place for them until it is necessary to use fire heat or keep that structure close.

These plants are quickly ruined in a close confined atmosphere. They must have plenty of light and air to insure strong sturdy growth, which is the secret of fine spikes of flowers. The earliest plants may be tied down, and then allowed to come into flower if they are required. All later batches should be trained as they require it to their trellis, and all the flowers removed directly they appear. It is important that Mignonette be carefully supplied with water, never allowing them to suffer by the want of it, or the shoots turn woody and cease extending. Clean soot water in a weak state may with advantage be given to those that have filled their pots with roots. Strong stimulants must be avoided, for they are certain to prove fatal. In addition to the soot water we apply to the surface of the soil a little artificial manure about once a month, which keeps the roots active upon the surface and invigorates the plants.—B.

SOME NEW AND OLD POTATOES—THE GENERAL CROP IN IRELAND.

You did well in your leading article, last issue, to invite further information as to experience on the above gained during the past year. Besides the general farm crop I grow all the new varieties I can conveniently procure in an experimental plot, with the view of being able to answer the queries of my neighbours in reference thereto, and for my own information. Many of your readers do the same possibly, and can add further useful observations. Looking at the matter broadly after being much about in Ireland lately, I may sum up my experience by saying the general field crop has been one-third deficient as compared with last year. This is already becoming evident in 2d. per stone more than last year being charged by retail in the local markets. Three-fourths of the Potato crop in Ireland and Scotland consists of the Champion, the "seed" or "sets" coming principally from the latter to the former. If the Champion, or rather "Scottish Champion," fails, what variety shall take its place? This interests millions. Already the haulm, no matter how manured or grown, is less than half the height and with half the vigour it had when first introduced. Every variety degenerates. If anyone denies this let him take up a list of varieties of thirty, or even twenty, years ago, and see where they are grown now.

The Magnum Bonum with me, too, is not so vigorous or as heavy a cropper as in former years, and what is worse, though the past season did not encourage fungoid diseases—being an unusually dry one—a larger fraction of the crop is diseased than the last or previous. It is, however, like the Champion, still one of the freest from blight. Both those varieties being grown the largest of any others in the United Kingdom I take them first; they are, however, different in every respect. Take one essential point rarely remembered. The Champion should be used for the table from September to May, the Magnum Bonum from April to August. I have heard the Magnum Bonum described as only fit for cattle and

swine, but on inquiry I found this was because it was used at the wrong time.

The same thing, but in a less degree, applies to such heavy croppers as White Elephant, Vicar of Laleham, Adirondack, and Wormleighton Seedling. I am inclined to name a new variety, the Helen Potato, I had last year for the first time, but I reserve it for further trial. Beauty of Hebron is of fairly good quality, not so early as Early Rose or Extra Early Vermont, but, like all Potatoes of American introduction, they flicker for a few seasons and degenerate in our moist and semi-sunless climate. Patterson's Victoria, Regents, Kemps, White Rocks, Porter's Excelsior, and Schoolmaster, either from degeneracy or a predisposition, are too liable to disease to ever regain the extensive culture they formerly had. For early use I ask nothing better than Sukreta (Carter's) I had last year for the first time; but for general purposes, everything considered, I consider Reading Hero the Potato of the immediate future. Grown side by side with two newer Scottish introductions on the farm—viz., Scottish Queen and Emperor, I readily give it the preference.—W. J. MURPHY, *Clonmel*.

ANNUAL MEETING OF THE YORKSHIRE

ASSOCIATION OF HORTICULTURISTS.

ADDRESS BY THE REV F. D. HORNER.

[At the last annual meeting of the above Association, held at the rooms of the Paxton Society, Wakefield, the Rev. F. D. Horner delivered an interesting address upon the general objects of the Association, and this was supplemented by a lecture on the Auricula. We have been favoured with the MSS. of both these, and as they are of far more than local interest we present them to our readers.]

(Continued from page 355.)

THE AURICULA.

I WILL ask you to take my own feelings about this beautiful spring flower "as read." I am speaking only of that section of the flower known to florists as the Auricula, and I will only say of my acquaintance with it that I have known it from my very childhood. To the first Auricula Show I ever saw my father led me by the hand, and I had to stand on tiptoe to see the plants upon the tables. With none other interruptions than those which needs must come across the path of life between childhood and man's estate, I have kept the Auricula in sight; and to all those who are conversant with it the flower has evidently within late years, say the last twenty, been passing through a very progressive era of its culture. In the present stage of its history it has quite turned over a new leaf. It had the character of being a difficult, almost immovable flower, and a plant of fastidious tastes.

Variation of course could always be had from seed at, so to say, about a year's notice; but improvement was thought so like crying for the moon that few attempted it. Many old growers would never save seed, and thought it an impious thing to risk the life of a valuable plant over seed-bearing. A few would grow seed saved by such florists as the late George Lightbody, but they were looked on as embarking in an enterprise that would be fruitless—men who would never succeed in rounding the Cape of their Good Hope. "You do not know to what vanity and vexation you are committing yourself. Be content to live on the labours of the past. You cannot, in the Auricula, be better than your fathers were." Thus the old sorts and the few gems among them came down from hand to hand, revered as venerable heritages beyond which there were no great expectations. Between one leading flower and its next great rival years and florist generations might intervene, as, for example, between the appearance of the grey edge Lancashire Hero in 1846 and its next illustrious class fellow G. Lightbody in 1860. But this was no innate obstinacy in the flower. There is found no extraordinary risk in letting a healthy young plant, however valuable, carry seed; and now that branch of culture which was supposed to tend nowhere but to an endless variety of tormenting disappointments affords the keenest enjoyment and richest results.

I should like at the outset to remove any impression if such there be, that the Auricula is a flower to be frightened of, in the sense of being a difficult, miffy, slow thing to grow. It has great adaptability to hard circumstances. The plant is perfectly hardy, easily handled, moveable at almost any time, quite content with a 4-inch pot, of short convenient habit and great and varied beauty of foliage, tolerant of a smoky air, a plant of a simple and regular life, and by no means the epicure in the complex and not nice composts which old time treatise on its culture tell us were the necessities of its life. It was never likely to get such indigestibles naturally, and that alone is enough to prove them needless and worse. In duration of life it is what I may perhaps call a limited perennial, one stem or plant living a few years more or less, and giving off a few offsets from time to time that perpetuate the parent variety in all its identity. No such identity is possible from seed, for no two seedlings are ever alike. The florist Auricula as we have it is so far removed, so far

developed past resemblance to any wild original, that it is nothing but of an acquired flower. There is therefore this touching point in its history, that its very existence, in all its fascinating distinct elaborated beauty, depends upon its finding new friends as old ones pass away. It has no native country. Like the dog it has left all its (wild) kindred and made its home with man. If it once were lost not our children's children could in their lives recover it.

I do not know what light upon its early parentage may be thrown by the Primula Conference to be held next year in London. The Auricula will be a prominent Primula there, for the Conference is to be held in its presence—on its show day in the south (April 23rd, 24th). There is the Primula Auricula of the Alps, for one remote ancestor of our cultured flower, and its nearest relatives (wild with us) are the Mealy or Birds'-eye Primrose (*P. farinosa*) and also *P. scotica*. Then there is *P. marginata* with serrated mealed foliage of recognisable resemblance and lilac flowers, with rudiments of that meal which is so intensely developed on the Auricula. There are several more Alpine species with a habit of foliage in white and green, quite that of the Auricula, together with such others as *Primula intermedia*, *pubescens*, and *viscosa*, with pink and purplish flowers and the habit of diminutive Auriculas. So have *P. glaucescens* and *Wulfeniana*, but the texture of their foliage, hard and almost horny, is distinct. In fact, all primitive and allied forms are a far remove from the flowers derived through so long a period of culture as the 300 years in which there have been Auriculas, says Gerarde, in English gardens. Those early varieties are described as being yellows, browns, and purples, all of them favourite colours still among seedling Auriculas. Browns and purples are not to be wondered at, for such their immediate parents may have been. But the persistency of yellow is remarkable, it is the expression of a wonderful kind of early impress or memory of the flower. For instance, I grow no yellows, but yet among maiden seedlings as they bloom a few yellow ones generally come. Yellow selfs will come from self parents of any other colour but that. Even the edged flowers, type furthest removed of all from the simplicity of wildness, will exhibit a like impression of a prehistoric past, and a seedling, say from a green-edged parent, will take indeed the emerald edge, but substitute for a black body colour some fanciful tint of yellow.

As to the derivation of the Auricula, to some extent, and certainly as to its progress in a very great degree, my belief is that the flower will tell its past history best and most convincingly itself. It might be tried with what wild species it would hybridise while in its infinite variability from seed, by which attribute it has the fundamental qualification for being what is known as a florist flower, it makes the most interesting revelations of the past to the raiser of its seedlings. In them the history of the past will repeat itself in varied retrospect, and among those that must be discarded as missing the standard they were intended to equal or excel are many in which the very faults are but tracings of their derivation towards its distant sources. They show how petals now substantial round and flat had been flimsy frilled and pointed, the dense meal thin and ill defined, and how the beautiful edge of green or pearly grey or snowy white was at first a slight and broken rim.

I am keeping for the Conference a special seedling, of best parentage, that is not worth a single mark in any one property of the florist Auricula. It is a highly worthless flower in that respect, but still perfect in its wilful way. It reminds me of an oil painting for which Mr. Barlow once gave 1s., and said if it were one touch the better he would not give 1d. for it. It was some warlike scene apparently, but the vendor said opinions varied as to the subject. It had been taken for the battle of Waterloo, and I know when we counted for curiosity the legs in a front file of soldiers, who seemed to have no particular reason to be where they were, we found that one warrior had three! That was a priceless discovery, for a man is oftener a leg short than one over in action.

(To be continued.)

HOUSES OF MIXED GRAPES.

I THINK it is generally admitted that where gardeners are able to devote a whole house to the growth of one or two varieties of Grapes that are found to do well together, the task of producing fruit of the highest excellence is much easier than where many varieties are grown together. In gardens where the means at command are great and the grower confines himself to a few good sorts, with good culture the result is certain to be highly satisfactory. But there are many who like to grow a number of varieties for certain good points that each possesses, either for their good colour, fine berries, exquisite flavour, large bunches, sure cropping, and free-setting qualities, and Grapes, like many other

garden products, are grown to look at as well as to eat. I believe the gardeners who are well acquainted with the best varieties of Grapes are well able to decide for themselves which are the better suited to their wants, according to the circumstances in which they are placed. Those who have had experience in the management of vineries in which numbers of varieties are grown are well aware of the difficulties of this system of cultivation during the flowering and ripening periods. A Vine of one variety will often come into flower two or three weeks before another growing beside it, and when seven or eight varieties are grown in one house the flowering time will extend over four or five weeks, which necessitates keeping the atmosphere of the house much drier than is good for either the foliage or the Grapes that are swelling while the backward varieties are still in flower. This evil is still greater when colouring commences, many of the varieties requiring much longer to ripen and a higher treatment than others.

It is not my intention to depreciate the system of mixed planting, because if it were not adopted many would be unable to grow some of the best varieties in cultivation, nor could they keep up a supply for so long a time. I think, however, by taking notes of those that come into flower and ripen about the same time under similar treatment, and also by turning to good account the warmest and coolest parts to be found in most vineries, the evils above mentioned may be in a great measure counteracted. With this end in view I append the result of my own observations in that direction, and I have no doubt that many much more able than myself could supplement these remarks should they think the subject worthy of their consideration.

In planting early Vines, consisting principally of Black Hamburgh, many cultivators like to have one Vine of Muscat of Alexandria in order to get that much-esteemed variety in presentable condition as early as possible; but I have never yet seen it quite satisfactory under such conditions, and I think such varieties as Foster's Seedling and Buckland Sweetwater are preferable for the dessert or the exhibition table till Muscats can be had in really good condition. Black Hamburgh, Madresfield Court, Buckland Sweetwater, and Foster's Seedling will succeed well together in an early house; and if the Sweetwater is planted in the warmest position, Foster's Seedling in the coolest position, and the other two varieties occupy the rest of the house, three of the varieties will ripen about the same time. The Madresfield Court will require longer time to do so, but the cool treatment necessary when the others are ripe will just suit this variety, provided the hot-water pipes are kept warm in dull weather to prevent the berries cracking. For a midseason house I am of opinion that Gros Maroc, Alnwick Seedling, and Madresfield Court would succeed well together, but I cannot speak from experience on that point; perhaps anyone who has grown them together will be able to give us a little information about these three fine Grapes.

Muscats should, if possible, have a house to themselves, although Trebbiano, Mrs. Pince, and Gros Guillaume will do very well under the same conditions; but if the bunches of the latter variety are large they will require a much longer time to ripen than even the Muscats, which, of course, is an objection, because the Muscats will shrivel from the effects of the fire heat necessary to finish the Gros Guillaume. The two varieties that require a longer time to ripen than others that I am acquainted with are Gros Colman and Gros Guillaume. Mrs. Pince is almost as long, and these three succeed well together and make a grand show. Gros Colman should have the warmest position. Another good combination for a late house is Lady Downe's, Alicante, and Abercainy Seedling. I do not wish to infer that these are the only varieties that will do well together, because it is a subject that may be experimented with in so many ways, but the varieties mentioned are safe ones to plant together. Perhaps there are others who may be induced to give us the result of their experience in the matter.—H. DUNKIN.

SELECT PASSIFLORAS FOR STOVE AND GREENHOUSE.

BEAUTIFUL and numerous as other genera and species of stove and greenhouse climbers are, but few can surpass in beauty the magnificent family of Passifloras, with their gorgeously coloured flowers and handsome fruit and foliage. Travellers in tropical America describe in glowing language the rich character of the scenes presented to their eyes by the handsome foliage, flowers, and fruit hanging in festoons on the long shoots of the Granadilla (*P. quadrangularis*), which climb from tree to tree in the forests. The fruit of the Granadilla, which is deliciously sweet and fragrant in flavour, is much esteemed by the natives of those tropical regions as an article of food, and even in England it is highly esteemed by some, and forms a valuable adjunct to the dessert. The latter, however, rarely produces fruit in this country unless planted out and can make root and growth unrestrictedly, and even then to insure fruiting the flowers must be artificially fertilised by the pollen of another species, as its own pollen is impotent. A few other species, such as *P. edulis*, *P. incarnata*, and *P. laurifolia*, are usually described under the general term of Granadilla, as all produce edible and luscious fruits, but with the exception of the species described as the true Granadilla and *P. edulis* these are not generally grown in English gardens. The last-named is, perhaps, more grown than the former, as it is more accommodating in its requirements, and will grow, flower, and fruit freely in a greenhouse or intermediate temperature.

Those whose experience has been confined to growing these beautiful climbers in pots can form no idea of their real character of growth and freedom of flowering when planted out and allowed to grow unrestrictedly, especially so in the case of the many beautiful hybrids between *P. alata* and *quadrangularis*, and *vice versa*, of which *Buonaparte* (fig. 59),

Decaisneana, and *Impératrice Eugénie* are charming examples. We have the three latter varieties, with *P. quadrangularis princeps*, *P. alata*, and *P. edulis* planted out at intervals in a bank of rich soil consisting of equal parts good turfy loam, peat, leaf mould and sand, thrown up round the inner walls of a large octagon house. Here they grow vigorously and

and temperature. *Impératrice Eugénie* was the first to bloom in May. Its petals are rosy lilac, and the filaments of the corona violet and white; leaves, three-lobed, and of a dark green colour. It lasted in bloom from May to the end of August. It has a graceful habit of growth, and is supposed to be a hybrid between *P. alata* and *P. quadrangularis*, or *cœrulea*.

Fig. 59.—PASSIFLORA BUONAPARTEA.

develop their true characters more fully than when grown in pots, but this vigour is not maintained at the expense of its freedom of flowering. The temperature of this house never exceeds 55° in winter, and is often 7° or 8° below that. No fire heat is employed after the end of May until the middle of September, and we may mention by the way that *Combreum purpureum* is planted out and growing freely in the same house

P. Buonapartea is one of the most handsome of the *Passifloras*, both as regards foliage and flowers. This, too, is a hybrid between *P. alata* and *P. quadrangularis*, possessing the sweet-scented and richly coloured flowers of the former with the handsome foliage of the latter. It possesses the merit of flowering freely in a young state, quite the reverse of its parents. It is a moderate grower, and in a cool temperature the leading

shoot does not run up without making abundance of lateral shoots. The laterals when 1 foot to 18 inches long commence to flower freely. The flowers are borne singly in the axils of the leaves, the petals of which are of a beautiful reddish crimson, slightly pointed at their outer extremities, with a corona of rich red, white, and blue filaments, and deliciously sweet-scented. Leaves large, ovate-acuminate, and of a rich dark green colour. This variety should have precedence of all others where space can be afforded for planting it out.

P. Decaisneana is a hybrid between *P. quadrangularis* and *P. alata*, with flowers very similar in colour to the latter variety, but has a more slender and straggling habit of growth. It is a variety well worth growing where plenty of space can be given it to grow, but is inferior to *P. Bonaparteana* in many respects. The well-known species *quadrangularis* has already been mentioned, and it will suffice to say that it is a magnificent climber, with flowers of the same character as its two hybrids just described. The fruit is very handsome when any can be induced to set and come to perfection on the plants; but, as has already been stated, resort must be had to artificial means to do so.

Of the remaining popular and well-known species, *P. princeps* or *racemosa* and *P. edulis*, much has been written concerning them from time to time. We may mention for the benefit of those unacquainted with them that *P. princeps* is a beautiful species, with simple smooth lanceolate leaves, a slender habit of growth, and brilliant scarlet flowers borne in racemes, which hang suspended from the main and lateral stems. *P. edulis* is a very free-growing and flowering species, with slender habit of growth and dark green, three-lobed, smooth leaves. The flowers, which are borne in profusion, are white and blue, and these are succeeded by dark purple egg-shaped fruits, which, when eaten, are of a delicious flavour. This variety will succeed in a cool greenhouse.

All of the foregoing are readily propagated by means of the young growths taken with a heel of the old wood in spring, and inserted in sandy soil under a bellglass or in a propagating frame. It is necessary to occasionally prune the stronger-growing kinds to keep them within bounds. This is best performed early in the year before growth commences. *Passifloras* are very much subjected to mealy bug and thrips, but these can be kept in check by use of the ordinary remedies.—T. W. S.

THE NATIONAL PEAR CONFERENCE AT CHISWICK.

THE Exhibition of Pears at Chiswick must be regarded as equally successful in its way as the Apple Congress of two years ago, for though the total number is smaller than was provided at the last-mentioned gathering, the most sanguine of the Pear Conference promoters could not have expected that between 6000 and 7000 dishes, representing so nothing like 40,000 fruits, would be obtained. Yet such is the case, and these exhibits fill the large vinery and two marquees of considerable size, making a display of Pears such as never has been seen before and probably never will be again. It is also thoroughly representative, for there are contributions from all the principal English counties, together with some from Ireland, Scotland, the Channel Islands, and France, and we see all gradations from perfect specimens to the undersized examples produced by trees in unfavourable northern districts. Taking the grand fruits from Barham Court, Maidstone, as the best of the English produce, a gradual decrease in size can be traced in the fruits as we go north, until the same varieties from far up in Scotland can be scarcely recognised, except where they have been grown in orchard houses, and then they attain as good proportions and appearance as if they had been grown out of doors several hundreds of miles farther south.

The suitability of different stocks to dissimilar soils or districts is readily seen, for a variety may be noted in one collection particularly fine from the Quince stock, and in another it will be seen equally good from the Pear stock. The greatest difference in size of fruits, though, appears to be affected by the form of tree or training adopted. Thus the samples from cordons are throughout extremely good, and even in the south of England are generally much superior to all others, though fan-shaped trees and palmette verriers yield numbers of handsome specimens, as also do espaliers. From bush trees some good fruits are shown, and after these come the standards and pyramids as regards the size of fruits, though the bulk of the exhibits are probably from the latter, especially in the southern contributions. Upon all these matters much information of great interest will undoubtedly be afforded when Mr. A. F. Barron has been able to tabulate and arrange the innumerable facts that the exhibitors have furnished in connection with their collections.

The following report is a record of the principal exhibitors in the various counties, and the varieties named are those which for size and general appearance were the most notable in the several collections, and therefore to some extent indicate which are best suited for the districts where they were grown. In the northern counties few varieties are named, for in the majority of cases they are not of full size, especially from trees out of doors.

MIDDLESEX.—As remarked last week, this county heads the list in number of exhibits, surpassing Kent, which was foremost at the Apple Congress. This is chiefly due to several large trade collections and to the wonderful collection of the Society's Chiswick garden, which is the largest from one establishment in the whole Exhibition. It comprises 212 varieties, the majority of which are fairly represented, but there are necessarily some small ones amongst so large a number, many of the varieties being of little value. All the best in cultivation are, however, well shown, and the collection altogether is most creditable to the garden. Very interesting, also, is a collection from Messrs. J. Veitch & Sons, Chelsea, which comprises 120 dishes. This is a handsome exhibit, the fruits above medium size from pyramid, espalier-trained, and cordon trees, but chiefly from the first-named, and on the Quince stock, though there are also some fine specimens from Pear stocks. The best fruits are of the following varieties:—*Duchesse d'Angoulême*, *Louise Bonne de Jersey*, *Beurré Capiaumont*, *Marie Louise d'Uccle*, *Gansel's Bergamot*, *Glou Morceau*, *White Doyenné*, *Beurré Hardy*, *Seckle*, *Kingsessing*, *Beurré Bachelier*, *Doyenné Gris*, *Beurré Diel*, *Pitmas-*

ton Duchess, *Vicar of Winkfield*, *Bellissime d'Hiver*, *Princess of Wales*, *Triomphe de Jodoigne*, *Uvedale's St. Germain*, *Calebasse Grosse*, *Chancellor*, *Brown Beurré*, *Beurré Baltet père*, *Beurré d'Amanlis*, *British Queen*, *Easter Beurré*, *Marie Louise*, *Catillac*, *Brockworth Park*, *Durondeau*, *Huyshe's Victoria*, *Van Mons Léon Leclerc*, *Maréchal de Cour*, *Beurré Clairgeau*, and *General Todtleben*. There are also some fine fruits of *Bismarck* and the *Sandringham Apples*. Messrs. C. Lee & Son, Hammersmith, exhibit eighty-six dishes of good fruits, representing most of the varieties named in the preceding collection.

The contributions from private gardens are numerous, Mr. J. Roberts, Gunnersbury Park, Acton, having an excellent collection, the fruits chiefly from upright cordons on the Pear stock. Especially fine were *Marie Louise d'Uccle*, *Beurré Clairgeau*, *Pitmaston Duchess*, *British Queen*, *Beurré Superfin*, *Beurré Bosc*, *Doyenné Boussoch*, and *Baronne de Mello*. The others are from pyramids chiefly, also on the Pear stock; *Catillac*, *Marie Louise*, *Chaumontel*, *Duchesse d'Angoulême*, *Beurré Diel*, and *Easter Beurré* being most notable. Mr. Hudson, gardener to H. J. Atkinson, Esq., M.P., Gunnersbury House, Acton, has thirty-four varieties from orchard and pyramid trees of good medium size. Mr. G. Thompson, gardener to W. E. Wells, Esq., Croxby House, Hounslow, has twenty-four dishes of good even samples, the best in appearance being *Winter Windsor* from standard on the Pear stock, which is of fine colour and good shape. It is an interesting Pear, being one of those mentioned by Parkinson; but though handsome it is of little value, as it soon decays at the core. Mr. E. Chadwick, gardener to E. M. Nelson, Esq., Hanger Hill House, Ealing, shows a collection of forty dishes, the fruits mostly of fair size.

Mr. J. Woodbridge, gardener to the Duke of Northumberland, Syon House, Brentford, contributes thirty varieties, comprising large fruits of *Duchesse d'Angoulême*, *Uvedale's St. Germain*, *Beurré Diel*, and *Pitmaston Duchess*. Mr. A. Wright, gardener to E. H. Watts, Esq., Devonhurst, Chiswick, shows twenty-four dishes, in which some fine fruits of *Easter Beurré* from a tree on the Pear stock trained to west wall are very notable. Mr. R. Dean, Bedford, has a small collection of fourteen varieties, *Beurré Diel*, *Catillac*, *Nouveau Poiteau*, *Swan's Egg*, and *Marie Louise* being well represented. Mrs. Sanderson, Duke's Avenue, Chiswick, has fourteen dishes; Mr. Draper, Kinneswood Cottage, Acton Green, shows six dishes; and Mr. J. W. Odell, gardener to W. Barber, Esq., Q.C., Barrow Point, Pinner, contributes thirty dishes.

KENT.—From this county we have the finest examples of English Pears, which in size are second only to those from Jersey. Even from this favoured district much difference is observable in the size and condition of the fruits, proving how much depends upon culture. Prominent amongst the best, as might be expected, are the magnificent fruits from Mr. C. Haycock, gardener to R. Leigh, Esq., Barham Court, Maidstone, which, with the Jersey samples, are the great attractions of the Exhibition. In size, colour, and general appearance these are all that could be wished, and show the characters of the finest Pears to the best advantage. They are from cordons, palmette verriers, and pyramids, the fruit from the first-named being extremely handsome. All the under-mentioned varieties will be found there in first-rate condition:—*Grosse Calebasse*, *Easter Beurré*, *Doyenné du Comice*, *Triomphe de Jodoigne*, *Marie Benoist*, *General Todtleben*, *Beurré Clairgeau*, *Pitmaston Duchess*, *Emile d'Heyst*, *Beurré Diel*, *Bellissime d'Hiver*, *Nouveau Poiteau*, *Glou Morceau*, *Reine des Tardives*, *Louise Bonne de Jersey*, *Beurré Bachelier*, *Beurré Hardy*, *Beurré Superfin*, *Catillac*, *Beurré d'Amanlis*, *Passe Crassanne*, *Emile d'Heyst*, *Marie Louise d'Uccle*, *Fondante de Noël*, *Huyshe's Prince Consort*, *Vineuse*, *Bonne d'Ézée*, *Thomson's*, *Marie Benoist*, *Doyenné d'Alençon*, *Duchesse d'Orléans*, *Durondeau*, *Beurré Hardy*, *Doyenné Boussoch*, *Jersey Gratioli*, and *Beurré de Capiaumont*. With these is also included a dish of a Japanese Pear named *The Daimio*, which is recommended as very ornamental, bearing large numbers of globular bright yellow fruits that cannot, however, be rendered eatable by any form of cooking.

An interesting and beautiful collection of 100 varieties is staged by Messrs. George Bunyard & Co., Maidstone. Particularly fine are the following:—*Calebasse Grosse*, on the Pear; *Beurré de Capiaumont* of very fine colour, on the Pear; *King Edward*, large; *Gansel's Bergamot*, handsome fruits, on the Pear; *Catillac*, on the Quince; *Beurré Rance*, on the Pear; *Beurré Hardy*, on the Quince; *Doyenné d'Alençon*, on the Pear; *Belle de Noël*, on the Pear; *Uvedale's St. Germain*, on the Quince; *Durondeau*, on the Quince; *Glou Morceau*, on the Pear and Quince, equally fine; *Beurré Clairgeau*, also on the Pear and the Quince; *Pitmaston Duchess*, on the Quince; *Beurré Diel*, on Quince. Other notable varieties were:—*Beurré Bachelier*, *Doyenné Boussoch*, *Daimio*, *Bunyard's Baking*, *Flemish Beauty*, *Beurré Rance*, *Brown Beurré*, *Gansel's Bergamot*, *Huyshe's Bergamot*, *Beurré Superfin*, and *Fertility*. Mr. C. Davies, The Moat Park Gardens, Maidstone, has fifty dishes of fine fruits, the best being *Beurré Diel*, on the Pear stock, perpendicular cordon; *Beurré Bachelier*, on the Quince, similar tree; *Pitmaston Duchess*, on the Pear, oblique cordon; *Marie Louise d'Uccle*, on the Pear, oblique cordon; *Duchesse d'Angoulême*, on the Quince, pyramid; *Durondeau*, on the Pear, perpendicular cordon, very handsome; *General Todtleben*, on the Pear, perpendicular cordon; and *Marie Louise*, on the Pear, similar tree. Mr. W. Divers, The Gardens, Wierton House, Maidstone, has twenty-four varieties, the fruits of medium size. Mr. Thomas Bunyard, Ashford, has fifty-two varieties, including good examples of *Grosse Calebasse*, *Beurré Clairgeau*, *Pitmaston Duchess*, *Marie Louise d'Uccle*, and *Durondeau*. The others are mostly medium size, the curious little *Poplin Pear* being pretty.

Mr. Butler, gardener to H. J. Thomas, Esq., Sittingbourne, Kent, shows ten dishes of Pears, all handsome, well coloured, especially those from the Quince stock. Of these *Pitmaston Duchess* grown as a pyramid are extremely fine, *Louise Bonne de Jersey* is of fine colour, *Beurré Clairgeau* large, *Beurré Diel*, *Maréchal de Cour*, *Doyenné Boussoch*, *Marie Louise d'Uccle*, *Durondeau*, and *Emile d'Heyst*. Some of the best of those from Pear stocks are *Beurré Bosc*, *Jersey Gratioli*, *King Edward*, *Leon le Clerc de Laval*, *General Todtleben*, *Duchesse d'Hiver*, and *Dr. Troussau*. Mr. R. Smith, The Gardens, Kenwards, Yalding, Maidstone, exhibits eighteen dishes, comprising good specimens of *Gansel's Bergamot*, *Chaumontel*, *Marie Louise*, *Pitmaston Duchess*, *Beurré Rance*, *Glou Morceau*, *Catillac*, *Fondante d'Automne*, and *Beurré Bachelier*.

Mr. T. W. Sanders, The Firs, Lee, Kent, has a small but interesting collection of twenty-four varieties, including several French varieties. The

fruits are of good size, particularly the following:—Bergamotte de Millepieds, Marie Louise, Delices d'Hardenpont, Bezi Louvain, and Directeur Alphonse, all on the Quince stock. Mr. Selway, The Gardens, Updown Park, Sandwich, Kent, has thirty-two varieties, rather small. Mr. W. Rogers, The Cedars, Ashford, has twenty varieties; and Mr. W. Herrington, Bettborough Rectory Gardens, Sandwich, has twenty varieties, mostly small.

HAMPSHIRE.—Next in order of merit, though not in numbers, come the Hampshire Pears, as shown by Mr. W. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Winchester, who has ninety varieties, forming a beautiful collection, the fruits all of good size, clean, and even. The best varieties were as follows:—Beurré Diel, Calabasse Bosc, Colmar d'Arenberg, Winter Nelis, Catillac, and Urbaniste on the Quince. Durondeau on the Pear is shown of good size from bush trees, but fruits of the same variety on the Quince from cordon trees are equally fine in size and much better in colour. Beurré Beauchamp, good. Directeur Alphonse, fine from a cordon on the Quince. Pitmaston Duchesse on Pear, trained to a west wall, is much finer than same variety from pyramid on the Quince. Easter Beurré on the Quince. General Todtleben and Doyenné du Comice, both on the Quince, are finely represented, as also are Chaumontel, Verulam, Beurré Benoist, Beurré Sterckmans, Marie Louise, Gros Trouvé, Bellissime d'Hiver, Glou Morceau, Thompson's, Louise Bonne of Jersey, Beurré Hardy, and Maréchal de Cour. Rev. J. L. Carrick, Springfield School, Southampton, shows twelve varieties, Grosse Calabasse being very large, and Beurré Clairgeau of fine colour, all on the Pear stock. These were the only collections from Hants.

BERKSHIRE.—There is not a great display from this county; but Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, has twenty-eight dishes of fine fruits of Pitmaston Duchesse, Easter Beurré, Catillac, Doyenné du Comice, Uvedale's St. Germain, Bergamotte Reinette of a fine golden hue, and British Queen—all on the free stock. Mr. W. Allen, The Gardens, Rainshury Manor, Hungerford, shows eighteen dishes, his best samples being Duchesse d'Angoulême from the Quince, Beurré Clairgeau from the Paradise, and Beurré Diel from espaliers on the Quince. Mr. C. Howe, gardener to Sir R. F. Sutton, Bart., Benham Park, Newbury, has twenty-four varieties, Gansel's Bergamot and Doyenné Boussoch being especially good, while Mr. J. Lawrence Ardmillan, Caversham, Reading, has fourteen dishes of rather small fruits.

HERTFORDSHIRE.—There are several good representative collections from this county, and though the fruits are not large they are generally even and fairly satisfactory. Messrs. Rivers & Sons, Sawbridgeworth, show eighty varieties mostly from Quince stocks as pyramid trees, comprising very good examples of Beurré Bachelier, Catillac, Marie Louise d'Uccle, Durondeau, Beurré Clairgeau, Beurré Alexandre, Lucas, Bishop's Thumb (of fair size from Quince, double grafted), Pitmaston Duchesse, Lebrun, General Todtleben, Magnate; Princess, handsome; Beurré Diel, from an espalier, fine; Beurré Langelier; and Duchesse d'Angoulême. Messrs. W. Paul and Son, Waltham Cross, contribute 150 dishes, including good specimens of the following: Doyenné Boussoch, Marie Benoist, Doyenné Gris, Doyenné du Comice, Autumn Colmar, Gilgil, Gansel's Bergamot, Maréchal de Cour, Beurré Clairgeau, Beurré d'Anjou, Beurré Diel, Easter Beurré, Marie Louise d'Uccle, Catillac, Pitmaston Duchesse, and Triomphe de Jodoigne. Messrs. Paul and Son, Chesham, have eighty dishes of average-sized fruits, some of the best being Marie Louise d'Uccle, Bishop's Thumb, Doyenné Boussoch, Delices d'Hardenpont, Beurré Clairgeau, and Catillac. Mr. J. C. Mundell, gardener to Lord Ehury, Moor Park, Rickmansworth, contributes sixty dishes of good fruits generally, including fine samples of Catillac, White Doyenné, Gansel's Bergamot, Beurré Clairgeau, Uvedale's St. Germain, Marie Louise d'Uccle, Doyenné Boussoch, Beurré Bosc, Glou Morceau, British Queen, and Beurré Clairgeau. Mr. Norman, gardener to Marquis of Salisbury, Hatfield House, Herts, has a collection of unnamed fruits, some of good quality.

SURREY.—The most important contribution from this county was that of 110 varieties from Mr. G. W. Cummins, gardener to A. H. Smea, Esq., The Grange, Wallington, which was a good representative collection, the fruits not of great size, but even and clean. The best varieties were Beurré Clairgeau, fine colour; Beurré Superfin; Beurré Diel; Doyenné du Comice; Catillac; Forelle, brilliant colour; Gansel's Bergamot; Uvedale's St. Germain; Bezi Mai; Beurré Diel; and Duchesse Tardive, a very free variety, in season from December to February. Mr. W. Shepherd, Greenhurst, Capel, Dorking, exhibits a small collection, chiefly from cordons on the Quince, but, except in a few cases, the fruits are not large.

Other exhibitors are W. Roupell, Esq., Harvey Lodge, Roupell Park, twenty dishes; Mr. T. Taylor, gardener to J. McIntosh, Esq., Duneevan, Otlands Park, Weybridge, twelve dishes; Mr. B. Greaves, The Gardens, Broom Hall, Dorking, twenty dishes; Mr. J. Coombes, Sheen House, Gardens, Mortlake, thirty dishes; Mr. J. Dean, gardener to G. Leveson, Esq., Titsey Park, Limpsfield, twenty-four dishes; Mr. A. Evans, gardener to J. S. Hodgson, Esq., Lythe Hall, Haslemere, twenty-four dishes; Mr. D. East, gardener to F. Wigan, Esq., Clare Lawn, East Sheen, eleven dishes; Mr. H. Matthews, Betchworth, thirty dishes; Mr. F. Ewerson, Grove House Gardens, Roehampton, twenty-four varieties, of good size and colour; Mr. E. Burrell, Claremont, Esher, twenty-four dishes; Mr. J. Forbes, Dover House Gardens, Roehampton, thirty dishes, a handsome collection of fine fruits; and Mr. J. Burnett, The Gardens, Deepdene, Dorking, fifty-five dishes, capital samples.

SUSSEX.—Some good fruits are shown by Sussex growers, prominent amongst whom is Mr. S. Ford, gardener to W. E. Hubbard, Esq., M.P., Leonardslee, Horsham, who has seventy-eight dishes of good average fruits, principally from pyramids on the Pear stock. The leading varieties are Vicar of Winkfield, Durondeau, Nouveau Poiteau, King Edward, Uvedale's St. Germain, Allman's Sussex Monster, Beurré Clairgeau, Chaumontel, Pitmaston Duchesse, Beurré Bachelier, General Todtleben, Thompson's, Duchesse d'Angoulême, Beurré d'Anjou, and Marie Louise d'Uccle. Messrs. J. Cheal & Son, Crawley, have a handsome collection of fifty-four varieties, many of which are from the cordon trees which they grow so well in their nursery. The following are capitally represented—Beurré Bachelier, Pitmaston Duchesse, Calabasse Grosse, Beurré Clairgeau, Uvedale's St. Germain, Beurré d'Amanlis, Van Mons Léon Leclerc, Catillac, Duchesse d'Angoulême, Beurré Diel, Beurré Hardy, Maréchal de Cour, Jersey Gratioli, Chaumontel, Vicar of Winkfield, Olivier des Serres, Doyenné du Comice,

Doyenné Boussoch, and Durondeau. Mr. Breese, gardener to Lord Leconfield, Petworth, has fifty dishes, all excellent fruits of good size, chiefly from cordons on the Quince. The principal varieties are Duchesse Tardive, Beurré d'Anjou, Doyenné du Comice, Durondeau, Marie Benoist, Pitmaston Duchesse, Calabasse Grosse, Beurré Bachelier, Beurré Diel, Marie Louise d'Uccle, Emile d'Heyst. Others equally fine were Uvedale's St. Germain, Bellissime d'Hiver, Catillac, and Beurré Clairgeau.
